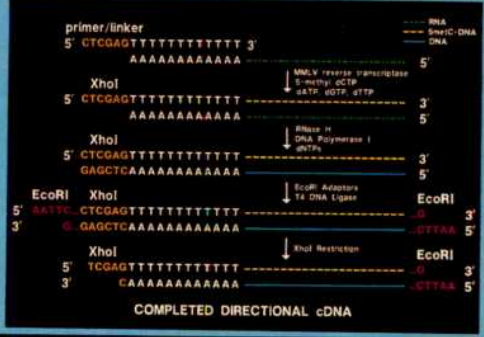
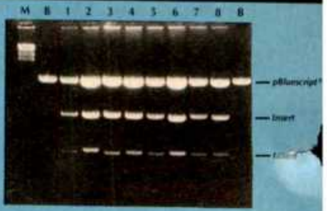
cDNA Synthesis

One Way is the Best Way

- ***Undirectional cDNA***
- ***Fast: Fewer Reactions Than Most Kits***
- ***Efficient: Up To 2.5 x 10^7 Recombinants Per 5 Micrograms of mR***
- ***Easy: No Enzymatic Methylation Required***
- ***Complete: Everything Included (except radiolabel)***
- ***Expression Libraries In the Lambda ZAP® II vector***
- ***RNase H Method For Extended 5′ Ends***
- ***No Linkers***



cDNA with Xho I and EcoR I ends is constructed with the rapid and efficient procedure diagrammed. The procedure is unique in that an **Xho I linker/primer** is used to prime first strand cDNA synthesis. In addition, **dCTP is replaced by 5-methyl-dCTP** in the reaction. Second strand synthesis and EcoR I adaptor additions are performed according to standard protocols. With this procedure the Xho I sites in the cDNA **but not in the linker/primer** are methylated and protected from digestion with Xho I.



A test RNA template is provided in the cDNA synthesis kit. Construction of a test library with this template **in your laboratory** verifies that full length, directional clones that contain the internal Xho I site are obtained with Stratagene's cDNA kit. Shown is an agarose gel analysis of clones obtained from a library constructed with the test RNA template. Eight recombinant clones were excised from the Lambda Zap® II vector *in vivo* in the pBluescript® plasmid and digested with Xho I and EcoR I; all clones exhibit the expected restriction map, demonstrating that all aspects of the kit performed optimally.
M: markers, B: pBluescript® plasmid/EcoR I/Xho I.

HARMACIA LKB BIOTECHNOLOG

1 9:00

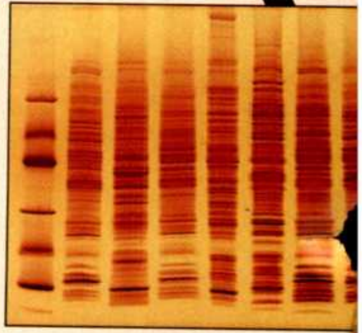
Choose a precast gel from an extended range of 9 different PhastGel® media. Place gel and buffer strips in the separation unit.

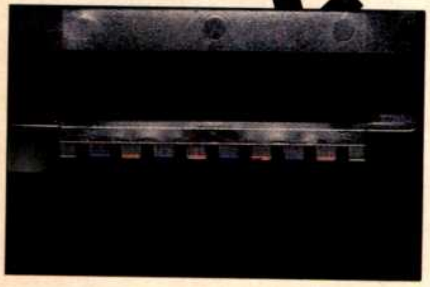
3 9:07

Program and run the method.

4 9:37

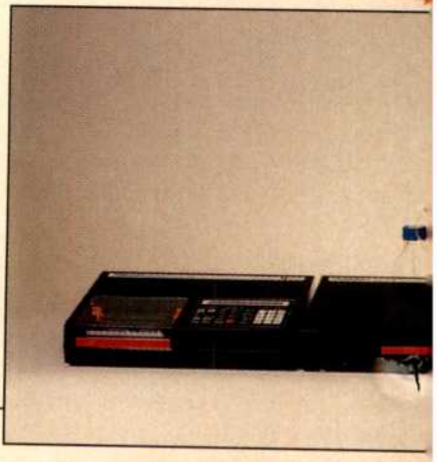
Develop the gel automatically with silver or coomassie staining kits.





2 9:02

Load sample. Application is automated.

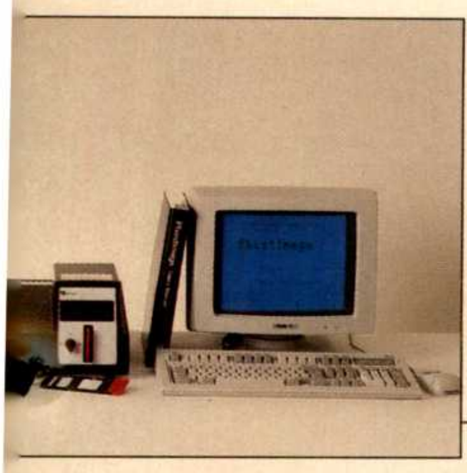


6 steps ahead

With PhastSystem™ you're at least 6 steps ahead of where you'd be with a conventional electrophoresis system. In the same time it takes to cast gels and prepare buffers for a conventional system, you could be ready to store results from a protein analysis run on PhastSystem. In less than an hour you can obtain accurate and reproducible results from any typical SDS- or native-PAGE separation. And an average isoelectric focusing run takes just 30 minutes.

HARMACIA LKB BIOTECHNOLOG

5 9:37
Transfer proteins to a membrane in 15 minutes.



6 10:07
Scan and evaluate your results.

Once you've gotten ahead, PhastSystem helps you to stay ahead. For fast, reproducible and economic transfer of PhastGel media results, we now offer *PhastTransfer*™, a new electrophoretic blotting system. With the small format of PhastGel media, PhastTransfer uses less detection reagents than other electrophoretic blotting units. And it consumes only 5 ml of buffer.

Then when you need to accurately and reproducibly evaluate results – whether they are in a PhastGel, an autoradiographic film or a PhastTransfer membrane – image analysis with the help of *PhastImage*™ is the final step. PhastImage is easy to operate and the same scanning procedure is used for one and two-dimensional gels.

After scanning, PhastImage determines band boundaries, defines the baseline, determines the optical densities of the bands or spots and integrates the volume. With the help of a personal computer for instrument control and data evaluation, PhastImage dramatically increases the information handling capability of PhastSystem.

PhastSystem — it's about time.

The Molecular Biology of Immune Diseases and the Immu

..........15 Years of Monoclonal Antibodies

For more than two decades, the Symposia have been the premier forum for applied molecular biology. Please join us once again for a double-barreled program highlighting basic research and commercial application:

Plenary Sessions

MONDAY (morning)
Antigen-Specific Receptors
Fred Alt, Columbia
James P. Allison, UC-Berkeley
Harald von Boehmer, Basel Inst.

MONDAY (evening)
Lynen Lecture*
Philippa Marrack
John W. Kappler
National Jewish Center for Immunology And Respiratory Medicine

TUESDAY (morning)
Distinguished Service Award**
Cesar Milstein

TUESDAY (morning)
Antigen Recognition and Lymphocyte Activation
Jack L. Strominger, Harvard
Richard D. Klausner, NIH
Dennis Y. Loh, Washington University

THURSDAY (morning)
Special Achievement Award***
Wallace Coulter, Coulter Electronics

FRIDAY (morning)
Molecular Mediators of Immune Pathogenesis
Kendall A. Smith, Dartmouth
Thomas Malek, University of Miami
Marian E. Koshland, UC-Berkeley
Eckhard R. Podack, University of Miami
Anthony Cerami; Rockefeller University

Molecular Pathogenic Mechanisms

MONDAY (afternoon)
Diseases of Abnormal Antigen Receptor Formation
Ilan R. Kirsch, NCI-NMOB
Hitoshi Sakano, UC-Berkeley
Terence Rabbitts, MRC

TUESDAY (morning)
Molecular Mechanisms in Autoimmunity
Lawrence Steinman, Stanford
Chella S. David, Mayo Medical School
Bonnie Blomberg, University of Miami

TUESDAY (afternoon)
Disordered Regulation of Lymphocyte Activation
Cox Terhorst, Harvard Medical School
Mark L. Tykocinski, Case Western Reserve
Ira H. Pastan, NIH

THURSDAY (morning)
Genetic Disorders of Surface Molecules
Gerald T. Nepom, Virginia Mason Research Center
Bernard F. Mach, University of Geneva
Yee Hon Chin, University of Miami

THURSDAY (afternoon)
Molecular Mechanisms of Immune-Mediated Tissue Injury
Victor Nussenzweig, New York University
Joan Stein-Streilein, University of Miami
Gilla Kaplan, The Rockefeller University

Biotechnology and the Monoclonal Antibody—The Second 15 Years

MONDAY (afternoon)
Receptors, Immunological Structure, and Pharmaceutical Development
Mark I. Greene, University of Pennsylvania
Donald C. Wiley, Harvard
Jeffrey Greve, Molecular Therapeutics
Eckhard Wimmer, SUNY

TUESDAY (morning)
Manipulating the Monoclonal I
James Larrick, Genelabs
Andreas Pluckthun, Max Planck Institute–Martinsreid
Jorge Gavilondo-Cowley, Center for Genetic Engineering and Biotechnology–Havana

TUESDAY (afternoon)
Manipulating the Monoclonal II
Ellen S. Vitetta, University of Texas
Peter G. Schultz, UC-Berkeley
Christopher L. Reading, M.D. Anderson Cancer Center
Sherie L. Morrison, UCLA

THURSDAY (morning)
The Biotechnology of Allergy
Kimishige Ishizaka, Johns Hopkins
Kevin W. Moore, DNAX Research Institute
Jean-Pierre Kinet, NIH
Tse-Wen Chang, Tanox Biosystems

THURSDAY (afternoon)
New Directions in Immunogenetics
Ursula Storb, University of Chicago
Tak W. Mak, University of Toronto
Charles J. Epstein, UC-San Francisco

*Lynen Lecture sponsored by GIBCO/BRL, a division of Life Technologies
**Distinguished Service Award sponsored by Elsevier Science Publishers
***Special Achievement Award sponsored by the University of Miami School of Medicine
****Monday morning Plenary Session sponsored by Boehringer Mannheim

Response.........Molecular Pathologies..

Molecular Pathogenic Mechanisms.
The immune system is an information processing and communication network rivaled only by the nervous system itself. The complexity of its molecular genetics and the subtlety of its cell-to-cell communication—their function and malfunction—have inspired some of the best science of recent decades, research that has provided a wealth of new tools, powerful ideas, and potential products—from vaccines to allergy, from human gene therapy to arthritis and AIDS; from the monoclonal antibody to interferon and erythropoietin.

Biotechnology and the Monoclonal Antibody—The Second 15 Years.
In a decade and a half, the monoclonal antibody has become a dominant force in molecular biology—a cornerstone of successful research and the foundation of nearly every biotechnology product now on the market. The future promises not only hundreds of new applications in familiar modes, but new forms of molecules applied to new kinds of problems—vaccines, anti-cancer therapeutics, drugs for treating heart attack, even the solution to common allergies. We will see how far this still-new technology has come, and try to discern where it will go by 2005.

Posters.
Periods of free communication, in the form of poster sessions, are scheduled for the morning of Jan. 22, the afternoon of Jan. 23, and the morning of Jan. 24. Poster presentations will be published as Short Reports in the Conference Proceedings (IRL Press/Oxford University Press). Authors of selected posters may be asked to give 15-minute oral presentations at general symposia sessions. For more information, please write to Short Reports at the conference address, or call 800-642-4363. **The deadline for poster submissions is November 1, 1989. If your research is relevant, please contact us now.**

Placement Service.
For decades, the Symposia have brought employers and job-seekers together. If you are looking for a position in academia or industry, or are looking for a top candidate, register on the attached coupon,or call .

Workshops.
During non-conference hours, the Symposia's popular technical workshops will offer hands-on introductions to help you master the latest in research tools and concepts.

Hotels.
Reservations for reduced-rate Symposia housing should be made through the central housing office, not through the individual hotels. You will receive housing information when you register. Or call 800-MIA-GENE for more information.

Travel Arrangements.
Discounts of up to 50% are available through the Symposia's agency. Call Travel Services Group at 800-336-0227 for details. Please refer to the Miami Bio/Technology Winter Symposia by name.

Sponsors.
The Symposia gratefully acknowledge the support of its major corporate sponsors:

- Elsevier Science Publishers
- GIBCO/BRL-Division of Life Technologies
- The University of Miami School of Medicine
- As well, Genentech has made a financial contribution to the Symposia.
- Boehringer Mannheim is sponsoring the printing of the final program.

Getting in Touch.
If you have any questions, please contact the Miami Bio/Technology Winter Symposia in the most convenient manner.

- By mail: P.O. Box 016129, Miami, FL 33101 U.S.A.
- By courier: Room 6054, Medical Research Building 1600 NW 10th Avenue, Miami, FL 33136
- Leave a toll-free message: 800-MIA-GENE (800-642-4363)
- Phone: 305-547-6265
- Telefax: 305-324-5665
- Telex: 519308

23 NOVEMBER 1989

Moderation of abortion debate

The chairman of the US Republican Party is not the most familiar source of wisdom on abortion, but everybody will benefit from what Mr Lee Attwater has learned in this month's elections in the United States

THE months ahead may see a marked attenuation of the public rows about the practice of legitimate abortion. That, at least, seems to be one of the portents of this month's elections in the United States, when New York elected its first black mayor, when governorships were up for grabs in states such as New Jersey and Virginia and when several candidates for less exalted offices discovered, against expectation, that a strong anti-abortion platform could be an electoral disadvantage. The shift was marked enough for Mr Lee Attwater, the chairman of the Republican National Party proclaim that his party is a tolerant party that welcomes a variety of opinions, even on matters as contentious as abortion. Most of the anti-abortionists disappointed at the polls appear to be Republicans.

That abortion is a contentious issue, and will remain so, requires no explanation. Whatever the resolution of the tediously familiar argument about the point at which human life begins (conception, implantation, the emergence of the neural crest or the like), there is no doubt that the majority of fetuses now aborted are alive by almost any criterion. That is why, where abortion is permitted (in the United States, abortion is the prerogative of state governments, but the Supreme Court could change that), explicit conditions must be satisfied before an abortion can be carried out. The general principle derives from the notion that if, at childbirth, there is a choice between the survival of the mother and of the child, the mother's life takes precedence. To be able to demonstrate, say by amniocentesis, that a fetus is genetically handicapped is not by itself a sufficient cause for legalized abortion, in principle, at least, it is necessary for a woman seeking an abortion also to demonstrate that the birth of such a child will be damaging to her, if not physically then psychologically.

Opponents of abortion are of three kinds: those who call abortion murder whatever the circumstances, those who complain that the conditions that must be satisfied before an abortion may be legally carried out are insufficiently stringent and those who complain that the preconditions are so loosely applied that legal abortion is elective abortion. The arguments for legalized abortion, in similar order of increasing moderation, are that a woman's body (and whatever is inside it) is at her own disposal (the feminist view), that unwanted children are genuinely damaging and that legal but regulated abortion is preferable to illicit practice on a similar scale. In an ideal world, governments would seek to blunt unresolved argument by diminishing the scale of the problem by post-abortion counselling and easier access to birth-control clinics, but these measures are not popular with extremists. Until this month's elections, this seemed to matter to politicians. It may be less important now.

This journal has no brief to grind an axe on the abortion issue proper and does not do so, but there are several related issues that affect what happens in laboratories. In the United States, the Secretary of Health and Human Services has just extended a moratorium on the use of fetal tissue in transplants out of — it now seems — misplaced respect for anti-abortion forces (see *Nature* **342**, 105, 1989). In Britain, the government's bill to regulate embryo research due to be published this week will be a vehicle for a parliamentary battle on abortion. But everywhere even those content with the legislation on abortion that may be in force should be concerned that its extreme opponents ('right-to-life' or 'abortion rights', as the case may be) are implacably opposed. It cannot much benefit grown-up societies that there should be apparently irreconcilable conflicts over the propriety of the law.

Despite a long history of bitter dispute, there is a chance that the two sides will be able to reach an accommodation with each other. That does not require that conflict should vanish overnight, but merely that people who are implacably opposed should learn that the other side has a case, but perhaps not the whole of what the extremists claim. Attwater may not be the most likely source of good sense on abortion, but his plea for tolerance deserves a hearing. ☐

Brain drain in flood

Migrations of skilled Europeans in the past few weeks are only the beginning. Employers should respond

BY the end of 1989, the numbers of people who will have moved permanently from one country to another will be a record for recent times. Even before the East German frontier with the West was opened last week, some 50,000 people had made their way around it in the previous two months. That exceeds, but not by much, the numbers who will have left the Republic of Ireland (mostly for the

United States) in 1989. Almost as a direct consequence, Turkish guest-workers will be displaced from West Germany in numbers comparable with those of the ethnic Turks being expelled from Bulgaria. In present circumstances, ethnic Hungarians in Romania would be heading for Hungary if their government would let them go, but the Soviet Union may end this year having lost 500,000 people, mostly to the United States and Israel. And then there are the boat people from Vietnam, not to mention those who escape from Cambodia while they can.

It is natural to regard these huge migrations as welcome signs of the liberalization of frontiers all over the world, but even voluntary migration is never trouble-free. People who complain of the trauma of moving house within a single country should multiply their impressions by some large number, say ten, to allow for the difficulties of settling into an entirely unfamiliar environment. That is why the populations picking up their own roots to go elsewhere are naturally self-selected to include the most employable, which means those whose skills are technical and thus most portable.

There is worse to come. If Eastern Europe and the Soviet Union now keeps to the spirit of the Helsinki agreements, *perestroika* will have to be made to work to keep the skill it needs where it is needed. But even within the West, the growing conviction that the European Economic Community will yet become a true common market will mean that there are quite unpredictable movements of skilled people between member countries, which will further complicate the general drift of people to North America. What the British call the brain drain will become a general phenomenon.

How can the losers in this new labour market defend themselves? The only simple answer is that they will have to pay market prices in some sense or another. That does not necessarily mean that money salaries must everywhere become identical; working and living conditions are also important. Researchers and academics generally, but also people with skills in electronics and computer usage, are especially vulnerable in present circumstances. Wise employers, governments included, should begin planning now for the structural changes required to succeed in the coming competition for competence. □

Conduct unbecoming

Runners-up to science prizes receive no recognition but should know better than to complain.

ONE of the stipulations in Alfred Nobel's will, finalized a year before his death in 1895, was that the prizes to be awarded annually in his name should be awarded for discoveries made in the preceding year. Almost without exception, this stipulation is disregarded. But another, which limits to a maximum of three the number of people who may share a prize, is still honoured. Dominique Stéhelin, a French virologist, continues to argue (see page 329) that he should have been the third person named for this year's prize in physiology or medicine, awarded to Michael Bishop and Harold Varmus.

As all agree, Stéhelin was the main pair of hands behind the experiments that first showed that the oncogenes of tumour viruses are stolen and corrupted versions of genes from the cells that the viruses infect. So much is acknowledged by the fact that he is the first author on the 1976 *Nature* paper that reported this discovery and which the Nobel assembly cite as the seminal piece of work. Nevertheless, only the head of the laboratory in which Stéhelin was a visiting scientist and the head of an associated research team have been awarded the prize.

Is this rough justice? With the absolute rule that all Nobel decisions are final and without appeal, it will be 50 years before the reasoning of the Nobel committees can be examined. It seems likely, however, that two questions that will have been asked are these: would Stéhelin, had he been working in any other laboratory, have been an author on the seminal paper, and would the paper have emerged from the Bishop/Varmus milieu even had Stéhelin not been there? It is likely that the answers were no and yes, respectively, considerably diminishing Stéhelin's case.

Nonetheless, there is no rule to stop the Nobel authorities from including Stéhelin had they so wished. Precedent was clearly against it, with the exclusion of Jocelyn Bell from the 1974 physics prize although it was she who spotted the pulsar for which, in particular, Antony Hewish was awarded his half of the prize, as a notable example. On the other hand, Georges Kohler, the visiting scientist who worked on the discovery of monoclonal antibody technology in César Milstein's laboratory, shared the 1984 prize for physiology or medicine. It is, of course, up to those who award prizes to set the rules but in the case of the relative merits of dirty hands to fertile minds there seems not to be one.

Stéhelin's immediate reaction was ungentlemanly. His claims can surely not have been overlooked. There is no doubt that it is harder to achieve international visibility in Lille than in San Francisco, but Stéhelin, who shared with Sydney Brenner and Walter Gehring the valuable and esteemed 1987 Jeantet prize for European biomedical scientists, was certainly in view from Stockholm.

But how wise is his new outburst, which seems largely to have been occasioned by some remarks by a member of the committee that recommended the winners? If the press has accurately reported these remarks, Stéhelin has some cause for complaint, but his response will do him no good. Even so, his contributions should be generously acknowledged at the prize-giving ceremonies in Stockholm next month. That will also be a time for the Nobel authorities to reconsider the terms of the prizes. With teamwork now the rule rather than the exception in research, for how long can they continue to award their prizes on the basis that the winners take all, and the runners-up receive no recognition? □

COBE starts its search for galactic fingerprints

- Satellite launched after four-year delay
- Looking for cosmic microwave irregularities

Washington

THE launch on 18 November, of the COBE (Cosmic Background Explorer) satellite from Vandenberg Air Force Base in California marks the start of a long-awaited astrophysical mission that had been delayed almost four years after the explosion of the space shuttle Challenger.

COBE's principal job is to look for irregularities in the cosmic microwave and far infrared backgrounds, an urgent task for cosmologists but one which has mostly passed beyond the capabilities of ground-based or balloon-flight experiments.

COBE was due to go on a shuttle flight soon after the Challenger disaster of January 1986, but NASA (National Aeronautics and Space Administration) decided shortly thereafter to switch it to a *Delta* rocket. This necessitated dismantling the finished satellite and putting the same instrumentation into a much smaller package. The reduction was achieved by omitting on-board thrusters, which would have been needed to propel COBE into its 900-km high, approximately polar orbit from the low shuttle orbit. The Delta launcher can put COBE directly into place.

The $160-million COBE satellite carries three instruments, and will scan the entire sky twice during it's one-year mission. By virtue of its polar orbit, COBE looks always at right angles to the direction of the Sun, whose light it must avoid to prevent damage to the detectors and interference with the measurements.

The two conical antennae of the Differential Microwave Radiometer will measure the difference in intensity of the cosmic microwave background, at three different frequencies, between two slightly displaced spots in the sky. This will yield an all-sky map of the variation of the microwave background from its average temperature of 2.7 K.

Temperature variations at some level are predicted by all theories of galaxy formation, the primordial variations in the cosmological density which acted as the 'seeds' of modern galaxies must also have left their mark as small irregularities in the microwave background.

Over the past two decades, experiments done from the ground, balloons and short-flight rockets have produced no conclusive detection of temperature variations. When the earliest experiments were done, simple galaxy formation theories predicted temperature variations of as much as one part in a thousand, but as increasingly sophisticated instruments have brought the upper limit down to as little as a few parts in one hundred thousand, galaxy formation theories have been of necessity refined and adjusted to creep under the lowering wire of the measurements. There is a general feeling now that theory has few recourses left, and that if COBE does not find any temperature variations at a level perhaps an order magnitude less than the present best observations, then revision of standard cosmological ideas may be unavoidable.

The job of another of COBE's instruments, the Far Infrared Absolute Spectrophotometer, has become more crucial during the enforced delay of the satellite's launch. Last year, researchers from Nagoya University and the University of California at Berkeley published measurements obtained by a rocket-borne detector which indicated a substantial excess in the background intensity at wavelengths between 1.0 and 0.1 mm, above the peak frequency of the microwave background, but below infrared emission from interstellar dust. The Nagoya–Berkeley team saw emission in this far infrared region an order of magnitude more intense than they expected, no convincing theoretical source has yet been identified, and some cosmologists believe that the detection is the result of some systematic instrumental error. COBE's far infrared detector should confirm or invalidate the Nagoya–Berkeley measurements, in either case telling cosmologists something about a region of the spectrum which, because of atmospheric opacity, has been little studied so far.

COBE's third detector, the Diffuse Infrared Background Experiment, goes to even longer wavelengths, and will look for emission which could be the accumulated radiation from distant, early galaxies.

By scanning the sky over a frequency range from microwave to infrared, COBE is in effect scanning the process of galaxy formation, from the imprint of density fluctuations retained by the microwave background to the faint, red-shifted emission reaching us now from the first generation of protogalaxies. Cosmologists are guaranteed to get something to think about, especially from the microwave experiment: if COBE finds the long-sought irregularities, they will at last have some numbers to put into their theories, if it finds nothing, they will need some new theories.

David Lindley

PRIZES

Nobel dispute continues

London

DOMINIQUE Stéhelin, the French scientist who claims he should have shared this year's Nobel prize in physiology or medicine, has expounded his case in an open letter to the committee that recommended the winners, Michael Bishop and Harold Varmus. But the committee has no intention of responding.

In his letter, Stéhelin amplifies his view that it is unjust to have excluded from the prize the person who carried out the crucial experiments for the key discovery cited in the announcements of the awards. He argues that his exclusion is strongly detrimental because the "prize carries an unparalleled aura and prestige, lending it absolute and unquestioned authority in scientific quarters and the eyes of the public", and requests that the committee finds a way to repair the damage that has been done.

Apart from the fact that his name does not even appear in the documents that accompanied the announcement, most of Stéhelin's complaints are directed at comments made by one member of the committee in response to Stéhelin's initial outburst. Erling Norrby was quoted in newspapers as saying that the French researcher had not published anything of interest since 1976, when the key paper by Stéhelin, Varmus, Bishop and Peter Vogt was published in *Nature*, and that whereas Bishop and Varmus's contributions had already been recognized by several prize awards, Stéhelin had none.

Stéhelin, who directs a unit within the Institut Pasteur in Lille, responds that among the more than 100 papers he has published since 1976 are reports of the discovery of six new oncogenes, and that he has been awarded four prizes, among which is the 1987 Jeantet prize for European biomedical research, which he shared with Sydney Brenner and Walter Gehring.

Jan Lindsten, secretary of the Nobel committee that recommended Varmus and Bishop, says that Norrby was speaking in a personal capacity, and that the committee will not be responding to Stéhelin. It is, he said, increasingly difficult to select the appropriate winners as research is increasingly a collaborative affair. While pointing out that the committee is empowered to consider only those who have been nominated, he refused to say whether there were any nominations for Stéhelin. Lindsten emphasized that the prize was given for more than the 1976 paper alone and that the parts played by Stéhelin and many others had been considered by the committee.

Peter Newmark

DATABASES

Johns Hopkins as international host

Washington

With funds from the Howard Hughes Institute (HHI), researchers at Johns Hopkins University (JHU) in Baltimore, Maryland, are planning an international network of databases to support the mapping and sequencing of the human genome. The selection of JHU as host to the first database in the network puts a question mark over the future of the human genome mapping library in New Haven, Connecticut, which is directed by Frank Ruddle of Yale University, and has been supported by the HHI since 1985. But Purnell Choppin, president of HHI, said that researchers at JHU are also seeking federal funds and if they are successful the institute will not fund the database next year.

The new database at JHU, formally named the Genome Data Base (GDB), will provide access to primary data and literature citations, and daily updates of information generated by scientific workshops, the database's scientific editors and individual laboratories.

Users will also have access to OMIM, the on-line version of Mendelian Inheritance in Man, Victor McKusick's classic encyclopaedia of human genetic diseases. Peter Pearson, who worked at the University of Leiden in the Netherlands before he was hired by the HHI to be scientific director of the database, says that he was given a choice between Yale and JHU as the home of a new, more modern database, and that access to OMIM was one of the reasons he chose JHU. With access to both GDB and OMIM, users "will certainly get more for their money", he said. Other databases with which Pearson also hopes to forge links include the mouse genome database at Jackson Laboratory in Bar Harbor, Maine, and that at the Centre d'Etude du Polymorphisme Humain in Paris.

The second centre in the network will be created in London, with the collaboration of the Imperial Cancer Research Fund. Data from the GDB will be transferred at the international human gene mapping workshop in the United Kingdom, and at every subsequent workshop the data will be updated and transferred to a new centre. Eventually there will be an international network of human genome databases.

Kenneth Kidd of the school of medicine at Yale University, a consultant to the Yale database, says that it is trying to obtain funds from other sources, including the federal government, to replace the support from the HHI which this year was about $1.2 million. The university was rejected as a candidate to host the new database amid complaints that the database there is in an outdated format, difficult to access and non-portable. **Christine McGourty**

NUCLEAR POWER

Japan presses on regardless

Tokyo

In spite of the growing anti-nuclear movement and the changing political environments, Japan is maintaining its commitment to expand nuclear power as its primary energy source, according to this year's white paper (policy document) on atomic energy, released last week by the Atomic Energy Commission (AEC).

Japan now has 37 commercial nuclear power plants in operation, supplying nearly 30 per cent of its electricity, and in its annual report two years ago the AEC outlined ambitious plans to increase that figure to 40 per cent by the year 2000. But in the latest report, such optimistic projections are conspicuously absent. The AEC notes that nuclear power has suffered setbacks outside Japan: in the United States, no new plants have been brought into operation for over a decade, West Germany has cancelled plans to build a nuclear-fuel reprocessing plant, and Sweden, Austria and Italy have voted against nuclear power.

Nevertheless, the Japanese report concludes that nuclear power is still "steadily expanding" worldwide and will remain central to Japan's energy policy.

But within Japan, opposition to nuclear power is growing (see *Nature* **333**, 199, 1988). In the past 18 months, the government and power industry has poured tens of millions of dollars into advertising campaigns, lectures and a telephone service to try to win back public support for nuclear power. But surveys earlier this year show that opponents of nuclear power outnumber supporters two to one (see *Nature* **337**, 494, 1989).

The government faces two severe tests of its nuclear power policy in the near future. A huge commercial complex to enrich uranium, reprocess spent nuclear fuel, and store low-level radioactive waste is scheduled to begin operations in 1991 in Aomori Prefecture, on the northern tip of the main island of Japan, but local farmers vehemently oppose the plan.

And in 1992, Japan hopes to start taking shipments of plutonium from Britain and France. The plutonium is derived from spent nuclear fuel from Japanese reactors, and is intended for use in advanced thermal reactors, Japan's first prototype fast-breeder reactor should become operational in 1992. But plans to ship the plutonium by air have already been abandoned because of opposition in the US Congress.

The AEC and the Science and Technology Agency (STA), which oversees Japan's nuclear power research and development, want to construct a new ship, to be operated by the Maritime Safety Agency, for plutonium transportation. But some members of the ruling Liberal Democratic Party (LDP) insist that existing ships of the Maritime Self-Defense Force should be used. However, despatch of these ships overseas is likely to cause public controversy, as it may violate military restrictions in Japan's post-war constitution. In addition, Japan has to face up to the problem of decommissioning nuclear reactors. Throughout the AEC report, nuclear power is referred to as "inexpensive" and "economical".

But the UK Central Electricity Generating Board, which has in the past promoted the low costs of nuclear power, had to admit at a recent public inquiry that the costs of decommissioning and waste disposal make nuclear power more expensive than coal power. This admission weighed heavily in the British decision two weeks ago to abandon plans to privatize the nuclear sector of the power industry (see *Nature* **342**, 213, 1989).

However, British reactors are bulkier, older and more inefficient than their Japanese equivalents. Yukiko Araki, deputy director of STA's Office of Atomic Energy Policy Research, said at a briefing on the AEC report that decommissioning and waste disposal are expected to increase the cost of electricity from nuclear power plants in Japan only to ¥10 (7 cents) per kilowatt hour from the present rate of ¥9. The power industry recently established a fund derived from utility charges to cover the extra costs.

But finding a site for disposal of Japan's high-level waste is another headache for the government. Early plans for deep-sea disposal were abandoned because of objections from neighbouring Pacific island nations. A borehole survey of a site on Hokkaido, Japan's northern island, has been carried out and, says Araki, the government plans to bury high-level waste there at a depth of hundreds of metres. But Hokkaido residents oppose the plan and finding alternative sites will not be easy, especially because of the prevalence of volcanoes and earthquakes throughout Japan.

Finally, the recent rise in strength of the Japan Socialist Party (JSP), following a series of money and sex scandals that have forced the resignation of two prime ministers this year, has added a new political force to the fight against nuclear power.

The JSP has traditionally advocated the abolition of nuclear power, but now takes the more pragmatic position that it will not expand the industry if it gains power in the imminent general election.

Araki says that people in the industry do not now expect Japan to reach the commission's target of 40 per cent nuclear-power-derived electricity by 2000, and that the Ministry of International Trade and Industry is working on new targets. **David Swinbanks**

EARTHQUAKE AWARENESS

Not just in California . . .

Washington

THE biggest earthquake of historical record in the United States occurred not on the West Coast but near the town of New Madrid, Missouri, about 200 miles north of Memphis, Tennessee.

During a period of seven weeks in 1811–12, three earthquakes, each of estimated magnitude greater than 8 on the Richter scale, altered the course of the Mississippi River, and were felt in Chicago and Washington. Although no very large earthquakes have hit the American midwest since that time, one of the political aftershocks of the recent Loma Prieta earthquake in California (see *Nature* **341**, 676; 1989) has been an effusion of public concern over the dangers of earthquakes throughout the country. In order not to be accused of geographical chauvinism, Congress held a hearing last week to discuss the activity of the New Madrid fault zone, and the readiness of local authorities to cope with a catastrophe.

Unlike the geological instability of the west coast, which occurs at the boundary of different tectonic plates, faulting in the New Madrid region is caused by a mid-plate rift. As in the Mid-Atlantic and Red Sea rifts, subterranean material wells up as lateral forces pull the plate apart, but the New Madrid fault, according to Dallas Peck, director of the US Geological Survey, is now virtually static. The faults are buried beneath alluvial deposits carried down by the Mississippi, making the system complex and unpredictable.

Empirically, faults between magnitudes 6 and 7 are estimated to occur about every 90 years. As recent events in California and Armenia have demonstrated, the difference between disruption and disaster from earthquakes of this magnitude has much more to do with building codes and education than geology (see *Nature* **337**, 107; 1989). Arch Johnston, director of the Center for Earthquake Research and Information at Memphis State University, said at the hearing that progress on a local statute enforcing tougher building standards had accelerated remarkably after the Loma Prieta earthquake, and that new laws could be in place by the end of this year. But those measures apply only to the city of Memphis and its local county, and contain no requirements for retrofitting of existing buildings.

Although these issues and others, such as the availability and cost of earthquake insurance, were seriously discussed, it is unlikely that any real initiatives will emerge from last week's hearing. As Don Ritter (Republican, Pennsylvania) put it, "the 1812 New Madrid earthquake is probably as far from the thoughts of the citizens of Memphis, Tennessee, as the 1812 overture is from the citizens of Nashville".

David Lindley

LOMA PRIETA EARTHQUAKE

Stanford in squabble over relief funds

San Francisco

STILL reeling from the physical damage, estimated at $160 million, suffered in the Loma Prieta earthquake on 17 October, officials at Stanford University, 40 miles south of San Francisco, found themselves on the public relations defensive last week after a senator in the California legislature maligned them for a lobbying campaign to get state relief funds that, it was suggested, were better deserved by more needy groups.

The controversy started when Democratic state senator Bill Lockyer tried to limit to $1 million the amount of state aid a private, non-profit institution such as Stanford could receive. But he quickly ran into opposition as the package wound its way through the layers of state government. First, the limit on funds was raised to $5 million. Then, when the bill was finally signed into law earlier this month by Governor George Deukmejian (Republican), the limit was waived altogether unless relief funds ran out.

The final form of the law upset Lockyer, who directed his anger at Stanford University. "Stanford was the main lobbying force arguing against any cap at all", he claimed, adding that representatives of the university attended all the discussions: they were "in the common hearings, at the lobbying gate, visiting people's offices and buttonholing them for the whole week". The senator was incensed that the wealthy institution used its considerable legislative weight to try and push through its package, especially as it has a $1,800-million endowment. "I'm not a Stanford basher", Lockyer said, "I think it's a wonderful institution, and their contributions to our culture are enormous." What irked him, he said, was that "a lot of other people or organizations that are less fortunate don't have similar capacities to take care of their own problems". For their part, Stanford officials were stunned by the accusations, and have written to the editors of both the campus paper and a local newspaper defending their actions. "I'm really surprised that this has somehow become newsworthy", said spokesman Larry Horton. He acknowledged that the cap was the subject of a major debate in the Senate, but said that the university was only supporting what it thought was the most reasonable position.

Robert Buderi

MAX-PLANCK SOCIETY

Zacher is new president

Munich

THE senate of the Max-Planck Society (MPS) last week selected Hans Zacher, now director of the Max-Planck Institute for foreign and international social law, as the organization's new president. Zacher, who was the only nominee presented to the senate, will begin a six-year term in mid-1990. He is the first president to emerge from the humanities section of the MPS in its 41 years, and succeeds Heinz Staab, who returns after his six-year term to the Max-Planck Institute for Medical Research in Heidelberg.

MPG/Filser

Zacher will take office in mid-1990.

With 62 institutes and an annual budget of DM1,240 million ($670 million), MPS is the largest research organization outside the universities in West Germany. Only ten of the institutes are in the humanities, the rest covering biology and medicine, chemistry, physics and technology. Zacher, who is 61 and a pioneer of social law research for whom the institute for foreign and international social law was founded in 1980, now faces problems familiar to the heads of all science organizations in West Germany: an expected wave of retirements among directors late in the next decade, accompanied by the need to find positions for a flood of young researchers. Some MPS members worry that the organization of the society is not flexible enough to handle all the changes (see Nature 340, 335; 1989).

Steven Dickman

PERESTROIKA

Market economy needed

Moscow

A transition to a regulated market economy, along with a large-scale decentralization of management, is the prescription given by the Soviet Academy of Sciences for the ailing Soviet economy.

These changes, and a number of urgently needed steps to bring them about, were recommended after a round-table discussion held at the academy on 9 November, and attended by economists, People's Deputies (members of parliament) and officials from federal ministries and departments.

Many of the recommendations are aimed at 'westernizing' the consumer market: to bring money that is at present held as individual savings back into circulation, housing and land should be put up for sale, and businesses should offer shares to the public; more industrial manpower and resources should be allocated to the production of consumer goods and services; more consumer goods should be imported directly, instead of being made from imported raw materials. At the same time, the academy recommends, measures should be taken to restrain wage growth and restrict credit. With these changes, experts say, inflation will fall from its present rate of 8–10 per cent per year to 5–6 per cent, and consumer shortages will largely disappear in three years.

To support this new strategy of gearing the Soviet economy to the needs of the population, there must be stable investment in heavy industry, a reduction in the output of mines and a slashing of military spending: this will permit the present investment in consumer goods production and the service sector to be doubled, and still allow a 50 per cent increase in social spending.

But the authors of the academy report, which is to be submitted to the Supreme Soviet and to the government, say that it will be impossible to maintain a Western-style consumer goods market without complete reform of the pricing system and the creation of free markets in investment and credit, in manpower and in convertible currency. The present system of price-setting, in which the prices of fuels, raw materials and chemicals, for example, can be greater or less than the going world rate by as much as a factor of two, is fundamentally flawed, the report declares, and should be gradually changed. By 1995, the ratio between the numbers of products with fixed and market prices could be 30 to 70.

With price reform and a massive changeover to wholesale trade, the academy believes that the range of products in short supply would begin to shrink and most goods would then begin to circulate freely on the consumer market. But some economists are more cautious, believing that a radically revised system can succeed only if shortages, and the consequent social tensions, are alleviated first. That problem is inseparably linked with the question of state subsidies for foodstuffs, which now total over 100,000 million rubles a year. Retail price reform would allow this figure to be reduced by as much as 75 per cent, but the population would have to be protected from the inevitable increases in foodstuff prices by comparable increases in income.

Concomitant with all this, a commercial banking system would have to be installed. The report foresees that a free money and investment market, coupled to a realistic foreign exchange rate, could take shape between 1993 and 1995.

But a genuine market economy has its own set of ailments, notably inflation, unemployment and bankruptcy. To safeguard the population against these negative effects of reform, the academy proposes, for example, linking wages wit some kind of regularly revised an published consumer price index. Th future of *perestroika* depends, the economists assert, on the ability of th government to overcome the public's distrust of the state, which means that th state must give up its universal proprietorial rights and concede the idea o diversified ownership.

The report criticizes draft Soviet legislation on leases, arguing that it constitute an insufficiently radical reform of stat property, and that it should be modified t allow unreservedly the rights of leaseholders to control income from a lease acquire productive assets and hire labour provided only that terms are agreed i advance. The academy also comments o a proposed new tax system, and says tha the minimum taxable income should b higher and the maximum tax rate, now 8 per cent, lower. **Oleg Borisov,** Novost

NUCLEAR PROLIFERATION

Nuclear technology for Brazil

Munich

Despite opposition charges that Brazil has used West German nuclear technology to develop bomb-making capabilities, West Germany last week extended, for five years, an agreement to provide Brazil with more technology. The government withstood a fiery attack in the Bundestag (parliament) from the opposition Social Democrats (SPD) and Green Party, who claimed that the government was pandering to industry. Brazil is a significant importer of West German nuclear technology, which has lost its domestic market.

The government says there is no proof that Brazil can make nuclear weapons, and points to a clause in the Brazilian constitution that forbids Brazil from developing nuclear weapons.

Ulrich Irmer (Free Democrat) cited in an October debate in the Bundestag a report prepared by the West German intelligence service *Bundesnachrichtendienst*, according to which Brazil is not capable of producing weapons-grade uranium.

Nuclear reactors in Brazil are subject to oversight by the International Atomic Energy Agency in Vienna, and the West German government says it is satisfied with these various safeguards. But the Social Democrats (SPD), who have been pushing for tighter export restrictions in sensitive areas such as nuclear power and chemical weapons (see *Nature* **337**, 678; 1989), say that government is not telling the whole story. Because Brazil has not signed the Nuclear Non-Proliferation Treaty (NPT), SPD Bundestag member Edelgard Bulmahn argues that it ma have a military programme intent o developing weapons. Only by signing the NPT, which would allow internationa monitoring of all its nuclear facilities could Brazil give a clear signal that it doe not intend to develop weapons.

The SPD cites the Brazilian military' so-called 'parallel programme' t develop nuclear technology as a threat and says that a reorganization of Brazil' nuclear programme in 1988 legitimize the drive toward nuclear weapons. Bu Claus Jäger (Christian Democrat), wh accused the opposition of trying to "stir u a scandal", says that government is "convinced" that nothing significant ha changed. The original West Germa agreement, signed in 1975, was to provide up to eight nuclear reactors as well a enrichment and reprocessing technolog to Brazil over a 15-year period.

Financial problems and technical hitches have led to a scaling-down, and Brazil now plans to build just three reactors.

Nevertheless, Brazil imports a considerable amount of nuclear technology from West German companies. Sources in the Bundestag estimated the value at DM 600 million ($330 million) in 1989 alone, and the collapse of the market for nuclear power plants in West Germany, along with the decision not to reprocess spe nuclear fuel at home, makes the nuclea industry more dependent than ever on foreign markets. **Steven Dickman**

■ For more on Brazil's nuclear capabilities, see page 374 of the supplement "Science in Brazil".

FRAUD IN SCIENCE

Indian zoologist suspected

New Delhi

A researcher at Bharatiyar University in the south of India is being investigated by the university for a deception allegedly practised on his British and US colleagues during scientific visits last summer. Professor G. Sundara Rajulu, head of the zoology department at Bharatiyar, has been accused by two US scientists of having 'perpetrated a hoax' by pretending that blood samples he collected in Britain came from a rare worm he claimed to have found in India.

The allegations were made in a letter written on 10 October to the chancellor of Bharatiyar University by Joseph Bonaventura, director of the marine biomedical centre at Duke University, North Carolina, and Charlotte Mangum, professor of biology at the College of William and Mary in Williamsburg, Virginia. Rajulu had spent two weeks as a guest in their laboratories during May and June.

The affair began when Rajulu contacted Bonaventura and Mangum, claiming that he had found haemocyanin, the copper-containing analogue of haemoglobin, in the rare Himalayan species *Eoperipatus Weldoni* a member of the phylum Onycophora. He wanted to bring some samples to the United States for further analysis. Onycophora are thought to be a link between annelid (legless) worms and arthropods, and the presence of haemocyanin could shed light on the link. Bonaventura and Mangum invited Rajulu to bring some live specimens to the United States for further analysis.

But when he reached their laboratories, Rajulu had no live specimens, and said they had been confiscated by US customs officials. Instead he produced a frozen blood sample and a preserved specimen of what he claimed was *E. Weldoni*.

The blood sample did indeed contain a haemocyanin typical of crustaceans, but on further examination turned out to have a general composition more characteristic of marine than land organisms. Mangum then discovered that Rajulu had come to the United States after a visit to Muriel Walker at the University of Leicester in England. An exchange of letters with Walker revealed not only that the blood sample Rajulu took to the United States was from a British shore crab, but also that he had told his UK hosts the same story about confiscated specimens that he had related to Bonaventura and Mangum.

Rajulu was supposed to have brought to Walker and her colleague Robert Harris live specimens of some other Himalayan creatures, but said that UK customs officials had confiscated all but one partial sample, which Harris later ascertained to be part of a common marine worm. The blood sample that Rajulu presented to Bonaventura and Mangum was collected at his request by Harris.

Rajulu admits he has been served with an "explanation notice" by Bharatiyar University, but is surprised at the fraud allegation because, he says, Bonaventura and Mangum expressed no doubts about his discovery of haemocyanin during his visit to their laboratories. But on 26 July, after he had gone back to India, Rajulu sent Bonaventura a brief note saying that "in my anxiety to do things I committed a lot of mistakes" and apologizing for the matter. But no other explanation of the incidents was offered.

The Indian National Science Academy has also been sent a copy of the allegations but has yet to take any action. Bonaventura and Mangum agree that no great damage was done by the incident, apart from the waste of several researchers' time, but want to have the matter investigated because Rajulu is in the habit of arranging annual scientific visits outside India. Mangum says she knows of trips to Korea, Belgium and Vancouver, but has had no success in discovering if any similar deceptions occurred on those trips.

JAPAN

Huge profit from drugs

Tokyo

JAPAN's hospitals and doctors are reaping enormous profits through sales of prescription drugs because pharmaceutical companies sell the drugs to medical professionals at a price far below the government's official reimbursement prices, an official of the Ministry of Health and Welfare admitted in the Diet earlier this month. The discounting practice has long been known to exist and is a major driving force behind excessive consumption of prescription drugs in Japan. But it is the first time a government official has put a figure on drug profiteering.

During a session of the auditing committee of the House of Representatives on 8 November, Tatsuhiko Sakamoto, director-general of the Health Insurance Bureau of the Ministry of Health and Welfare, under questioning by a member of the opposition Komeito party, revealed that the profits amount to about ¥1.3 million million (nearly $10,000 million) per year. Medical institutions charged patients and the health insurance system about ¥5.15 million million yen for drugs in 1987 on basis of the ministry's official prices, but Sakamoto estimates the actual cost to the institutions to be only ¥3.83 million million.

Unlike medical practice in most developed nations where doctors are not allowed to sell drugs, nearly all hospitals and general practitioners in Japan have their own in-house pharmacies. To promote sales, pharmaceutical companies sell drugs to medical institutions at below the government's official price (the price that determines charges). There is thus a strong incentive for doctors to overprescribe and to prescribe drugs unnecessarily because they make a profit on every sale.

The profiteering and overprescription is a massive drain on the national health system and also has serious consequences for the health of the nation.

One example is antibiotics. In the West, doctors try to avoid prescription of antibiotics because of the risk of development of antibiotic-resistant bacteria. But in Japan, antibiotics are liberally prescribed for all sorts of minor infections.

Another example is blood products. In the early 1980s, consumption in Japan surged with the import from the United States of cheap blood products which companies then sold to medical institutions at well below the government's official price. Among them were blood coagulants infected with AIDS, and most of Japan's 1,000 or so AIDS patients and carriers of the virus are haemophiliacs infected by the imported products.

For years, the ministry has been trying to separate the dispensing of drugs from doctors (a process called *bungyo* in Japanese). One approach has been to encourage the use of so-called 'legal prescriptions' which are handled by pharmacies outside the hospital. In response, large numbers of 'second pharmacies' have sprung up — although at first sight independent, they are in fact linked to medical practitioners. The doctor's wife, for example, may own the pharmacy.

Doctors and hospitals maintain that profits from drug sales are essential for management of their institutions. But slowly they are being brought 'reluctantly' towards full-scale *bungyo*, says Luke Gander of Pharma Japan, a newsletter for the pharmaceutical industry. But Gandor does not expect complete separation of doctors and pharmacies for 10 to 15 years.

There are too many vested interests to bring about rapid change. Pharmaceutical companies, both foreign and Japanese, are happy with their high sales in Japan. Doctors are happy with their profits. And the unquestioning Japanese public are happy to take home their bagfuls of unlabelled drugs after they visit the doctor. As the representative of one British pharmaceutical company observed, "It doesn't seem to do them any harm. The Japanese have the highest life expectancy in the world."

David Swinbanks

GENETIC TESTING

CF screening premature?

Washington

At its annual meeting last week in Baltimore, Maryland, the American Society for Human Genetics (ASHG) issued a statement urging caution in the use of screening tests to alert couples to the presence of a genetic defect associated with cystic fibrosis (CF) and the consequent possibility that their children might be born with the disease. Geneticists agree that testing should be offered when either partner has a close relative affected with CF, but say they have "serious reservations" about widespread screening.

The race to develop a new test was prompted by the announcement in August of the cloning of the gene for CF by researchers at the University of Michigan, the University of Toronto and the Hospital for Sick Children, Toronto (see *Science* **245**, 1059; 1989). Before then, CF could be detected only using conventional linkage analysis, which was available only to those with a family history of CF and with an affected relative still living. The discovery of the genetic mutation meant that a quick and cheap test could be developed based on a DNA probe specific for the mutation.

But the new test can still detect only about 70 per cent of CF carriers, because only that proportion of victims of CF have the identified mutation. Some researchers say that there should be no widespread screening for CF until the identification of additional mutations, which is expected within a year; others argue that the test is valuable despite its shortcomings and that widespread screening is worthwhile.

At its meeting last week, the ASHG erred on the side of caution, saying general screening should wait until a larger proportion of CF carriers can be detected and also until there is a better idea of the education and counselling that could be given to CF carriers. To this end, says the ASHG, pilot screening programmes should be started as soon as possible. Peter Lanciano, the general manager of Integrated Genetics Inc., one of the companies providing a CF test, endorsed the ASHG statement, saying that it would do a disservice to the public to rush ahead with widespread screening "just because you can do part of the work".

He said that the company will refuse to provide the test to anyone who does not have a family history of CF. Frank Fujimura, scientific director of molecular biology at the Nichols Institute said that the institute would advise against taking the test but would not refuse it. But he admitted that resources are not available for providing counselling services on the scale required for routine widespread carrier screening for CF.

Fujimara said that although the laboratories involved are highly regarded, there is widespread concern at the lack of mechanisms to ensure that standards are maintained. In last week's statement, the ASHG also called for centralized quality control; both it and the College of American Pathologists are considering some kind of certification procedure for laboratories. The ASHG is now establishing a working group to study all the issues raised by the new test and produce a report next year. **Christine McGourty**

HUMAN FRONTIER PROGRAM

Strasbourg office opens

Tokyo

The long-awaited opening of the office for Japan's Human Frontier Science Program in Strasbourg, France was due to take place on Tuesday, 21 November (see *Nature* 340, 329; 1989). As of 17 November, more than 130 research groups led by scientists from the seven summit nations (Japan, United States, Canada, Britain, West Germany, France and Italy) and the European Communities had applied for the 20 or so $500,000 grants that will be available, for research on the brain and molecular recognition, in the first year of full operation of the programme. Because of delays in opening the office in Strasbourg, the deadline for grant, fellowship and workshop applications will be extended to the end of this month, according to Toichi Sakata, director of the Frontier office at the Science and Technology Agency. David Swinbanks

BIOTECHNOLOGY

Celltech to change hands?

London

The major shareholder in Celltech, the largest UK biotechnology company, is to sell its 36.4 per cent holding. It is considered likely that potential buyers will bid for all of Celltech's shares.

British and Commonwealth Holdings has been a shareholder from the start of Celltech in 1980. It has decided to sell its shares for "strategic reasons", and has asked the board of Celltech to identify possible buyers.

The news follows an announcement by chief executive Gerard Fairtlough, that he is to stand down from the company he has led from the start. Celltech, best known for its monoclonal antibody products, recorded its first profitable year in 1987. Last year was also marginally profitable.

Peter Newark

FOOD IRRADIATION

Limited use approved in India

Bangalore

India's National Monitoring Agency (NMA), set up by the government to study the problems associated with food irradiation, has approved limited irradiation tests with a view to general commercial use of the process, which kills bacteria that cause deterioration of food. Food irradiation became controversial in India following public protests over the import by India of Irish butter-oil that was alleged to have been contaminated by fallout from the Chernobyl nuclear explosion.

But now M.R. Srinivasan, chairman of India's Atomic Energy Commission, says that the NMA has approved the irradiation of spices and frozen sea food for export, as well as the irradiation of onions for the home market. To further the prospects of commercialization, the Department of Atomic Energy has joined with Gujarat Agro Industries Corporation and the Spices Board of Kerala, and intends soon to set up gamma irradiation facilities in a number of places in India.

Radhakrishna Rao

SOUTH AFRICA

New CSIR president

Cape Town

Dr Brian Clark, 41, has been appointed president-elect of the South African Council for Scientific and Industrial Research (CSIR). The appointment was announced earlier this month by the Minister of Trade, Industry and Tourism, Mr Kent Durr. Clark will succeed Dr Chris Carberts, the current CSIR president, in September next year. He will be the sixth and youngest president of the organization, which is the largest of South Africa's three major research councils.

Clark joined the council's National Physical Research Laboratory as a technician after leaving school in 1965, and completed both his undergraduate and postgraduate training at the University of Pretoria as a part-time student.

Clark's present post in the CSIR is executive head of research, development and implementation (RDI). In this capacity he has been responsible for leading last year's restructuring of the organization into 12 technologically orientated divisions in the hope of attracting more research contracts from the private sector and government departments (See *Nature* 332, 197; 1988). In the current financial year, he expects outside contracts to amount to R174 million, accounting for 35 per cent of the RDI's budget.

Clark said in a statement that he hoped "to manage the CSIR in such a way as to make a major contribution to the ongoing development of South Africa".

Michael Cherry

WEST GERMAN UNIVERSITIES

Battle for youth plan

Munich

AT the same time as West German education minister Jürgen Möllemann has become the favourite of science organizations, he has become the bane of the education ministers of the *Länder* (states) in a simmering territorial dispute. Now he faces an all-out battle to gain support for a programme to support young researchers that could shape research and teaching at West German universities for the next 30 years.

Education had traditionally been a rump ministry when Chancellor Helmut Kohl chose Möllemann (Free Democrat or FDP) for the post in March 1987. When the ministry was created in 1972, the weekly newspaper *Die Zeit* wrote that if West Germany needed separate ministries for research and education, it should also set up separate ministries for letter post and parcel post. But circumstances besides his own ambitious nature helped Möllemann to overcome these hindrances: the FDP saw in the post a chance to put its liberal programmes across, and the federal budget was beginning to fatten after several lean years.

Möllemann soon realized that there is little for an ambitious education minister to do. His official brief covers just a few areas, including funding of the Deutsche Forschungsgemeinschaft (DFG), and construction at universities. So he began to try to steal areas of authority from other jurisdictions, mainly the *Länder* and, to a lesser extent, the Research Ministry.

Möllemann's style is to find a topical issue, overcrowding at universities for example, which brought students onto the streets a year ago in larger numbers than had been seen in 20 years (see *Nature* **336**, 704; 1988), then identify himself with the issue in the press — in this case by visiting the Munich university at the height of the unrest, where he was pelted with tomatoes. Finally, he makes a proposal to solve the problem: combined federal and *Länder* investment to provide more teachers and facilities in overcrowded fields such as business studies.

Möllemann's *Staatssekretär* Fritz Schaumann lists a number of achievements of which the minister is most proud: an increase in federal aid for students from middle-income families; the establishment of 40–60 graduate colleges to encourage more rapid progression to the PhD level; support for more research at technical colleges; and big increases in university building funds and for DFG.

For the long-term health of university research and teaching, the most important challenge is the plan to support young researchers for up to ten years until large numbers of professorships become available (see *Nature* **341**, 94; 1989). This could help to persuade the best young people to remain at universities instead of going into industry or business. Despite criticism from finance ministers and even some education ministers in the *Länder*, the plan still has a fair chance of being passed at a 21 December 'education summit' with Kohl and *Länder* politicians in Bonn.

But the government will be hard pressed to find the DM6,000 million ($3,200 million) that Möllemann wants for the plan. Priorities in Bonn have shifted since the huge influx of East German refugees began this summer.

West German education minister, Jürgen Möllemann.

Another important task, according to Schaumann, will be smoothing the way for the integration of West German courses of study into the European Communities, a tricky problem complicated by the differences in norms among the *Länder*, which fear losing autonomy to Brussels as well as to Bonn. Möllemann's activities have disturbed the *Länder*, to whom education policy is one of the last remaining bastions of power in an increasingly centralized country.

"Compared to what he has promised, the results are meagre", complains Thomas Goppel of the Christian Social Union (*Staatssekretär*) in the Bavarian Ministry of Science. "If he wants his programmes to succeed, he should discuss them with us first," says Goppel, "he achieves ten per cent of what he has promised and then sells it as success." And "Möllemann is only interested in headlines", says Uwe Knüpfer of the Social-Democrat-run science ministry in North Rhine-Westphalia: "he ignores issues where behind-the-scenes negotiations would be more helpful than publicity campaigns." Goppel and Knüpfer say that Möllemann has done more for his own career than for students and professors.

But Möllemann has admirers in the science organizations. DFG president Hubert Markl says the minister "should be given credit" for this year's budget increase; Markl's pleading fell on deaf ears in the parliament and the government until Möllemann made DFG an issue. And Dieter Simon, chairman of the *Wissenschaftsrat*, says Möllemann's concern for science has done a lot of good: "even though his suggestions are not always the best, the fact that he keeps making them is a big help." Even critics such as Goppel agree that Möllemann has given a higher education a "new valuation" in the public mind. But both supporters and critics say that the biggest test for Möllemann — gaining federal and *Länder* support for his ideas — lies ahead. He cannot afford to walk away empty-handed from the 21 December education summit or the lasting effect of his contribution will, in the words of Knüpfer, "vanish in a puff of smoke". **Steven Dickman**

RESEARCH FUNDS

More money for UK science

London

As part of UK Government expenditure plans announced last week, about £60 million will be added to the science budget for each of the next three years. Of the £61 million added to next years budget, £17 million is earmarked for the construction of a new research vessel for the British Antartic Survey. Small sums are also allocated to the British Geological Survey, to enable it to set up a National Geological Information Service.

Next year's budget will now be £897 million, 27 per cent more than was spent in 1988–89. The Advisory Board for the Research Councils, which had been pushing for an even greater increase, will be deciding on how the extra money should be distributed among the research councils.

A simultaneous announcement of extra expenditure on higher education anticipates a predicted increase in the number of extra students. A system of student loans is to be introduced as part of the plan to boost numbers. Peter Newark

Reasonable doubt?

SIR—George F. Wood's letter (*Nature* **341**, 100; 1989) suggests that some of your readers may not be aware of the legal profession's understanding of certain "issues involving probability". A substantial body of case law and commentary addresses the two issues he identifies. On the question of "what probability represents the 'reasonable doubt' beloved of the legal profession", see, for example, *Branion* v. *Gramly*, 855 F.2d 1257, 1263 n.5 (7th Cir. 1988) ("reasonable doubt means 0.9 or so, with adjustments depending on the gravity of the offense"); J. Kaplan *Stanford L. Rev.* **20**, 1065–1092 (1968). On the "purely statistical" proof of an elevation in "death rates due to . . . external circumstances", see, for example, *Sindell* v. *Abbott Laboratories*, 26 Cal. 3d 588, 163 *Cal. Rptr* 132, 607 P. 2d 924 (1980); D. Kaye *Am. Bar Fdn Res. J.* 487–516 (1982).

No paying twice

SIR—Henry Gee's News item (*Nature* **342**, 110; 1989) correctly explains the background and purpose of the programme of the European Science Foundation (ESF) on the molecular neurobiology of mental illness. ESF is asking for FF10 million ($1.6 million) from its member organizations to run this programme for five years. Clearly this sum will not pay for all of the science involved; in each ESF country, the cooperating scientists will have to use normal national routes to raise the research funds required.

The ESF's FF10 million will be spent largely on coordination: interchange between scientists, collection of new pedigrees, computer services and the initiation of Southern blot analysis of chromosomal regions outside the normal interests of mental illness specialists, to ensure complete mapping of the genome.

There can of course be no question of anyone "paying twice" for the same work – no ESF member organization would do that.

Gee reports the concern of scientists about two points. First, I can reassure colleagues that the formal code of practice of the programme contains provisions for allotting particular regions of the genome to research groups that can justify a deep involvement with that region. Otherwise allotment will be 'random' to ensure both fairness and complete coverage of the genome. Second, the data facility of the programme will not perform any linkage analysis unless help is specifically requested by the members supplying the data.

We hope that this programme will help to identify innate risk factors in mental disease and provide a tool for the refinement of psychiatric diagnosis. These are high ambitions; to further them, we must of course satisfy both our professional colleagues and the proper concerns of funding organizations. We believe we are doing so.

Purge the bombers

SIR—The problem of terrorist bombings of airplanes in flight might be solved by a simpler and possibly more effective means than large, expensive thermal neutron analysers (TNAs). Specifically, the solution can make use of the elementary principle in chemistry that oxidation, including spontaneous combustion of plastic explosives, requires oxygen. Exclusion of oxygen, rather than or in addition to bombs, from airplane cargo holds could be accompanied by purging with nitrogen, an inert, completely non-toxic and non-polluting gas comprising nearly 80 per cent of the Earth's atmosphere. Perhaps more realistically, the large bins used to contain checked passenger luggage could be purged, and the purge maintained through slow release of nitrogen from a liquid or (small and safe) compressed source within each bin.

This proposal to exclude oxygen from luggage bins can be economically implemented in airports of even the most technologically non-advanced nations. The universal problem of flight delays would be turned into a benefit by providing time before airplane take-off for nitrogen substantially to replace oxygen within each piece of luggage. To function, a terrorist bomb would have to carry its own oxygen supply, or use air contained within hermetically sealed luggage to support an exclusion of sufficient intensity to breach the nitrogen-purged luggage bin, whereupon the explosion could accelerate by using air in the cargo hold, assuming it has not also been nitrogen-purged. It should be easy to scan luggage for hermetic sealing and/or the presence of compressed oxygen. Nonetheless, it would be desirable to identify any or all conditions under which single pieces of luggage could carry sufficient non-compressed oxygen to sustain explosions of the intensity required to breach nitrogen-purged luggage bins.

In airports equipped with TNAs, nitrogen-purging can address the problem of unacceptably frequent false-positive TNA scans. Instead of manually searching numerous items of luggage yielding positive TNA scans, such luggage could be placed in nitrogen-purged bins, with some obvious trade-offs. As a final point, the feasibility of this low-technology solution can be tested in the short term, before major resources are committed to developing costlier high-technology solutions to be available only in the more distant future.

Nobel infallibility

SIR—The debate over the fairness or otherwise of the award of this year's Nobel Prize for Physiology or Medicine is reminiscent of the controversy over the 1952 prize for the discovery of streptomycin. This was awarded to Selman Waksman alone, specifically for his discovery of the antitubercular antibiotic streptomycin. Streptomycin was in fact discovered by one of Waksman's research students, Albert Schatz. Schatz had senior authorship on the main papers that announced the discovery and also appeared on the streptomycin patents. In addition, Waksman and others signed sworn affidavits to the effect that Schatz was co-discoverer. Finally, following a lawsuit, Schatz was legally defined as streptomycin's co-discoverer.

When Schatz's colleagues learned that Waksman alone was to be awarded the Nobel Prize for streptomycin, they began lobbying to correct the injustice. Some leading scientists, including William Feldman, sympathized with Schatz, but felt it politic not to intervene on his behalf. Amazingly, in reply to probing on Schatz's behalf, the committee that had awarded the prize admitted that it had never heard of Schatz. So much for the investigative abilities of the Nobel prize committees. It seems that nothing much has changed over the past 30 years or so. Indeed, the rules of the prize mean that no corrections can be made; essentially the Nobel committees regard themselves as infallible, and do not admit to mistakes. Stehelin should be warned that the scientific establishment does not take kindly to the Nobel prize boat being rocked. The career of Albert Schatz was blighted by his attempts to gain due recognition for his work. We can only hope that the same fate does not befall Stehelin.

Popper on Schrödinger

SIR—I have read, somewhat unwillingly, P.W. Atkins' review of a biography of my late friend Erwin Schrödinger, which appeared under the title "Physicist and philanderer" (*Nature* **341**, 193; 1989). I should be grateful if you would print this defence of a great man against the accusation of cowardice ("Schrödinger also appears to have been a coward . . .").

I do not know and I do not care who originated the accusation. But the accusation is absurd, as I will show. It illustrates how some people fail to understand the situation that prevailed in Germany and in Austria under Hitler.

Atkins writes of Schrödinger: "After fittingly succeeding Max Planck in Berlin in 1927, he (a Protestant) escaped to Oxford in 1933". This is a *suggestio falsi*: Schrödinger did not 'escape' from the Nazis, as did so many scientists (and others) who had been dismissed and who were threatened by a fate worse than dismissal. On the contrary, like Planck, von Laue and Heisenberg, Schrödinger was, in Hitlerian terminology, an 'Aryan', and like them he could have stayed in his position in Berlin and enjoyed wealth, power and influence. He did nothing of the sort. He gave up his position as the leading physicist in Berlin, and he chose, very soon after the dismissals had started in 1933, to join his 'non-Aryan' colleagues of his own free will. He did so with a public declaration expressing his disgust with Nazism.

Owing to the help of Professor Frederick Lindemann (later Lord Cherwell), he came to Oxford where I visited him in 1935 and 1936. I found him intensely unhappy. He was grateful to the powers that had made his reception at Oxford possible. But he was particularly unhappy about the scientific atmosphere there (or rather about the complete lack of it). He was not, of course, exclusively interested in physics: he was also very interested in classical scholarship. But he complained that, in Oxford, no serious discussion about scientific or scholarly problems was possible. It just was not 'done'. It was regarded as banausic. Instead, one gossiped about people — usually running them down — and often rejected them in spite of their obvious competence and devotion to their subject. Schrödinger rejected this kind of snobbery (as did Churchill); and some silly people interpreted his open rejection (the openness of an apparent refugee) as ingratitude towards Oxford, and even towards England, which Schrödinger loved. That he ever "abused" Lindemann, or that he showed him "ingratitude", I regard as absolutely impossible. But Schrödinger was unused to dissembling, was highly temperamental and even a bit irascible. And, as I know only too well from many discussions I had with him, he did not suffer fools gladly. But at the same time he was ready to make amends by showing special kindness. To say that he "considered himself to be God" is again absurd: he was very conscious of being far too frequently in the wrong, even morally.

During my visits to Oxford, when Schrödinger told me of his unhappiness, he also mentioned that he might leave Oxford and accept a chair in Austria which, in those days, was ruled by Schuschnigg who tried to keep the Nazis down. I implored Schrödinger to give up this mad idea. I told him that I was trying to leave Austria because Schuschnigg, who was after all a dictator like Mussolini and Hitler, was bound to succumb to Hitler. But Schrödinger thought that the allies would not let Hitler annex Austria — nor would Mussolini; and he said that, after all, if Hitler were to endanger Austria, he would emigrate again.

Not very long after this, I heard from Hans Thirring (my teacher in theoretical physics) that Schrödinger had declined Thirring's offer to vacate, in his favour, the chair in Vienna for a vacant chair in Graz, but that Schrödinger had himself accepted another chair in Graz.

In 1938, Hitler invaded Austria after a crisis of only a few days which left Schrödinger no time to escape (this time, the term 'escape' is appropriate). Being a known opponent of Nazism, he was at once in great danger. He was forced (like Galileo) to recant his anti-Nazi views; but being a little younger than Galileo was at the time, he managed an adventurous escape: he put a small suitcase with his most important documents into his old car and drove to the Italian frontier, where he left his car standing in a side road and crossed the frontier with his wife on foot. Once on the Italian side, he took a train to Rome. There he telephoned Dublin, trying to contact Eamonn De Valera, the Irish prime minister, who had invited him before. De Valera, he found out, was in Geneva. So he rang Geneva and, with some difficulty, reached him. He told him about his situation, and that his money was running out rapidly while he was telephoning. De Valera said he should at once take a train to Geneva. On the Italian–Swiss border, Schrödinger and his wife Annemarie were stopped by the *carabinieri*: they were forced to get out of the train, which left without them. They thought that the Nazis had alerted the Italian fascists. They were both searched, but they were allowed to continue by a later train. (It turned out that because they had hardly any money on them, they had been suspected of trying to export money illegally.) Once across the border they were safe.

Letters submitted for Correspondence should be typed, double-spaced, on one side of the paper only.

Some of my ('Aryan') friends in Austria managed to leave under tragic and dangerous circumstances. One of my closest friends, Otto Haas, a lieutenant in Hitler's army during the war, tried to organize a resistance movement and was hanged in 1944.

Some of my friends made their peace with Nazism. They were in danger for they had been *Judengenossen* (associates of Jews). Who is to blame them? Who is to call them cowards?

But Schrödinger was not one of them: he left Austria soon after its annexation under the most dangerous circumstances, even though he would have been welcomed by the Nazis had he recanted. Galileo did recant. Who dares to call him a coward?

A last remark on poetry, on *What is Life?*, and all that.

When in 1927 I first read Schrödinger's *Abhandlungen zur Wellenmechanik*, I was overwhelmed, not merely by the beauty of his theory, but by the sheer poetry of it: I knew then that he was a real poet. When, long after his death, I read some of his poems, I remembered, and felt confirmed in my opinion.

When I read, 40 years ago, *What is Life?*, I was greatly excited. But I soon realized that this was a kind of manifesto without much content; that Schrödinger the poet had run away with Schrödinger the scientist. After all, he was inspired by the views of Max Delbrück, and the book was meant as a popularization of Delbrück's ideas. (Schrödinger's own suggestion that what characterized a living organism was that it sucked up negentropy was not to be taken seriously, for every washing machine does that, without coming to life.) However, the book worked as a biologist's manifesto, and inspired many young people: no doubt, Schrödinger's poetic powers succeeded where, as I believe, his biology failed. Here, as everywhere else, I disagree with your reviewer. (But I largely agree with Linus Pauling, and more or less with Max Perutz, in their contributions to *Schrödinger*, edited by C. W. Kilmister, which was published by Cambridge University Press in 1987.)

A last word: gossip about Schrödinger's philandering is not my business; nor, I suggest, is it anybody else's business. And I find it hard to swallow that Annemarie Schrödinger is being made part of the gossip.

The nature of science

Sir—While A. Travis (*Nature* **341**, 10; 1989) may be bemused by the Universe, he is certainly befuddled about the nature of science. It would seem that, to Travis, only when a model can be "tested experimentally can it be held as truth". I, and I am sure many other scientists, would take issue with this statement.

Science cannot and should not claim to be discovering truths. As fallible human beings and scientists, our best hope is to propose theories (or hypotheses) that are rigorous enough to withstand repeated testing and to be supported by the evidence that can be gathered. Many of the theories simply will not withstand the testing and will either be falsified outright or, more likely, be replaced by a new and better corroborated theory. This is the strength of the so-called 'scientific method' in attempting to understand the world around us. It cannot proclaim ultimate truths as Travis would suggest, for those who do so step out of the realm of science.

A more debatable issue is whether only experimental science is truly science. Both the aforementioned statement of Travis and a later comment that "untestable theories in science (such as the evolution of life through random diversification followed by natural selection) are permissible, but not if they involve forces from an unknowable source", suggest that Travis would hold to the stricter 'experimentalist' perception of science. By most scientists' perception of their profession, however, if a theory is untestable it is not science and is not permissible, at least within the realm of science. The statement only makes sense if one replaces "untestable" with "non-experimental". If this is done, I have less quibble with the statement, because much of testable science is in fact non-experimental. Every science, but some more than others, has an historical component that represents a unique series of events that took place in the near or very distant past. The experiment has been run, but the evidence is there and can be corroborated over and over again just as an experiment can hopefully be repeated.

Sir—A. Travis feels compelled to invoke a 'creative force' when considering the mysteries of the observable Universe, in particular those aspects that appear least amenable to scientific investigation. I doubt, however, whether it is appropriate to label such areas of mystery as being particularly 'religious'. Such labelling is similar to that which became popular following the deistic movement of the early eighteenth century, in which 'god' or 'religion' were invoked to explain phenomena for which science had not yet found satisfactory theories. Not surprisingly, such a 'god-of-the-gaps' faded like the smile on the Cheshire cat as science continued its advance. The invoking of a 'creative force' to fill the present gaps in our scientific knowledge does not seem any more satisfactory. The task of science is to construct better and better 'maps' that will incorporate an increasingly sophisticated understanding of the world around us, and there is no reason to suppose that topics such as 'human intelligence' and the 'origin of life' will not be much better defined in future maps than they are on the rather poor ones that we have at present.

Those who laid the foundations of modern science in the seventeenth century did not look for gaps in their scientific knowledge in which to make room for their religious beliefs. Quite the reverse: they saw behind the complete 'map' of scientific knowledge a God whose continuing creative activity made it a worthwhile enterprise to look for consistency and reproducibility in physical phenomena in the first place. Their sense of awe at the world around them came not so much from its unexplained mysteries as from the fact that it was explicable, and could be expressed particularly in the language of mathematics. For example, Galileo saw God as the "divine mathematician", who had made a universe that was intelligible by the human mind, so that investigating "the true constitution of the universe" was "the most important and most admirable problem that there is"[1]. Three hundred years later, our investigations of the 'true constitution of the universe' have a very long way to go, but it is good to emphasize that religion, at least the kind of religion that Galileo espoused, still has no hidden investments in scientific ignorance. The role of religion and philosophy is to address the much broader questions of whether the very existence of the 'map' itself, with ourselves as part of it, has any particular meaning in a more ultimate sense, and also to tackle the vital ethical questions as to how our scientific knowledge should be used. Peter Medawar has recently reminded us that the scientific method itself is not equipped to provide answers for such questions[2]. But as we attempt to tackle them at other levels, the proposal of 'unknown, creative forces' as religious-sounding plugs for the gaps in our present scientific knowledge is as inappropriate for religion as it is for science.

Sahni visit denied

Sir—In normal circumstances, I would have ignored V. J. Gupta's statement (*Nature* **341**, 11–12; 1989) that my father, the late M. P. Sahni, had visited his (Gupta's) localities in 1964, as not being central to the main issues at stake in the matter of the 'peripatetic fossils'—see the article by Talent (*Nature* **338**, 613–615; 1989) and those by others (*Nature* **341**, 13–16; 1989). But the present situation is far from normal and warrants that the truth be made known regarding M. P. Sahni's involvement in the matter. Sahni had an unblemished and distinguished record of meticulously conducted research spanning nearly half a century. It is therefore all the more distressing that his name has been dragged into a controversy after his death, and this has provoked several of his friends, ex-colleagues and well-wishers to ask me to set the record straight.

The facts are that Sahni attended a seminar at Srinagar (Jammu and Kashmir) in October 1964. He left Srinagar on 16 October, seen off at the airport by Dr S.K. Shah, one of the organizers of that seminar and now professor of geology at the University of Jammu. During his brief halt, Sahni neither visited the graptolite localities nor did he accompany the post-seminar field excursion and I have documentary evidence to substantiate this.

The controversy over the 'peripatetic fossils' has caused intense introspection and soul-searching among Indian earth scientists in general and palaeontologists in particular. Open systems based on trust are fragile institutions prone to attack, but the strength of such systems derives from the internal reaction and response in the hour of crisis. By this yardstick, the national response has been spontaneous and extensive: exposure in the news media and the setting up of two major commissions of inquiry and other bodies of investigation. Introspection has led to action.

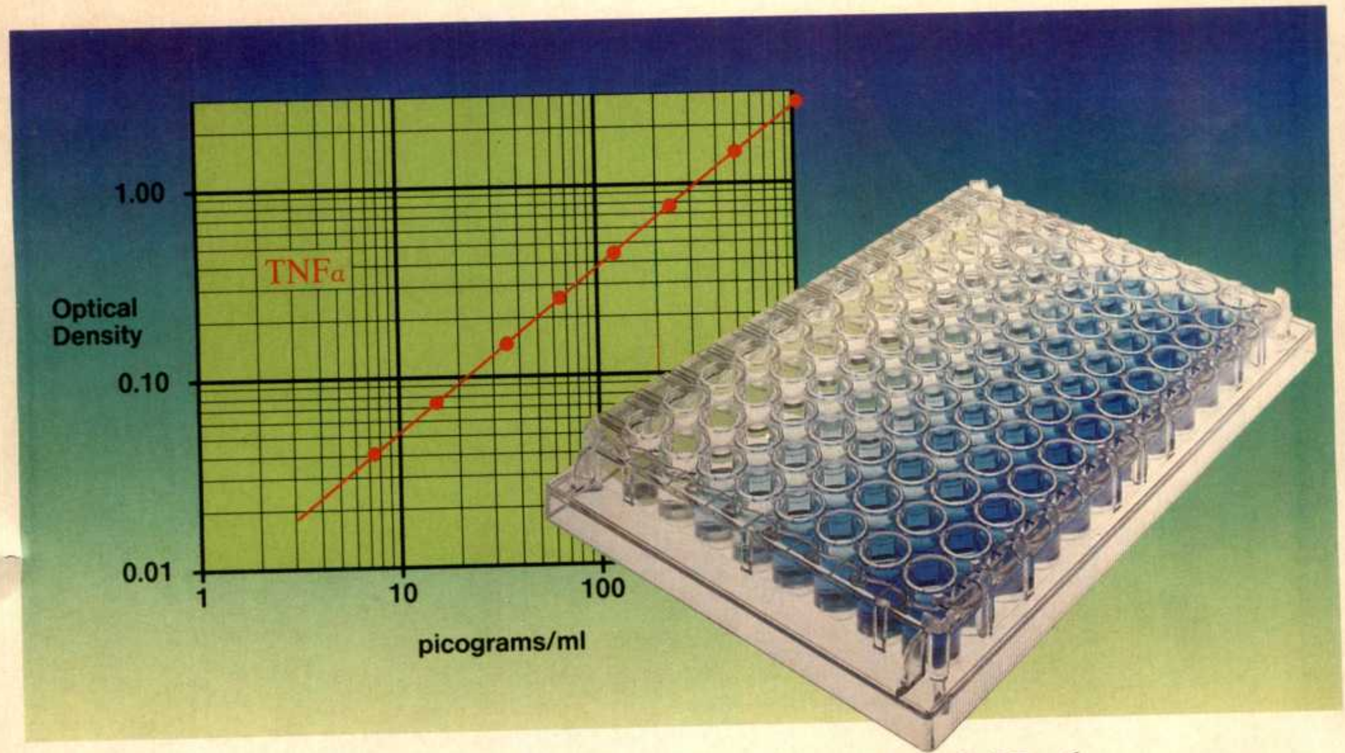
Quantikine™

For the Precise Quantitation of Cytokines.



ELISA Kits for TNF-α, IL-1β*, IL-4*, IL-6

R&D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive:	linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.
Precise:	well-to-well CV <8%
Specific:	results not influenced by the presence of other cytokines.
Accurate:	eliminates the inherent imprecision of bioassays.
Rapid:	simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample…Incubate (2 hours)…Wash…Add Detection Antibody…Incubate (2 hours)…Wash…Develop…Read Results.

To place an order or request product information, call us at **1-800-328-2400.**

Q: Why do we have radioactive waste anyway?

A: *All industries produce waste. The nuclear industry is no different. If we want the benefits of nuclear electricity and nuclear medicine we have to accept the waste. But even if we could stop using nuclear technology, waste that already exists would still have to be safely disposed of.*

Q: What sort of waste is UK Nirex Ltd. responsible for?

A: *Only low and medium level radioactive waste. Low level waste has been routinely disposed of for 30 years and medium level waste has been stored.*

Tough questions. Honest answers.

Q: Why isn't radioactive waste stored in the place it's produced?

A: *Many reasons. In particular it will be less safe in the long term to have stores dotted around the country close to man and the environment than to have one high quality disposal site protected by hundreds of feet of rock.*

Q: What is the likelihood of radiation escaping and harming people?

A: *The chances of anyone being harmed are less than one in a million, which is about the same as the risk involved in smoking just one cigarette in a year. Nothing can "leak" in the normal sense, as all the waste in a disposal centre will be set in concrete.*

Q: What's to stop radioactivity leaking into the environment?

A: *Multiple barriers are placed between the waste and the environment. These include steel drums, layers of concrete and the carefully chosen surrounding rocks, which will contain the waste for many thousands of years.*

Q: How will wildlife and plants be affected near the site?

A: *Nirex will take great care to make sure that the environment is safe and the site will be carefully surveyed to protect any rare or unusual species.*

Q: Who is responsible for making sure the highest safety standards are upheld?

A: *Ultimate responsibility lies with the Secretary of State for the Environment along with the Secretaries of State for Scotland and Wales. UK Nirex is also monitored by the Department of the Environment, the Ministry of Agriculture Fisheries and Food and the Nuclear Installations Inspectorate, as well as receiving advice on procedures from the National Radiological Protection Board.*

UK Nirex Ltd., a company owned by the Central Electricity Generating Board, British Nuclear Fuels plc, the UK Atomic Energy Authority and the South of Scotland Electricity Board, is to develop and build a deep underground disposal centre for radioactive waste. If you'd like more answers on radioactive waste disposal just phone our Information Line on 0235 833009.

SAFE FOR THE FUTURE

Reader Service No.8

Disentangling the greenhouse

Continuing uncertainties about the working of the greenhouse enhancement give the lie to those demanding, at a meeting last week in the Netherlands, that the details of an international convention should be settled on the spot.

Melbourne

EVERYBODY seems to know that this is the part of the Earth's surface at which the Antarctic ozone hole reaches furthest north. While the observations of anomalous springtime ozone depletion outside the Antarctic Circle covers only a single season (this time last year), people seem convinced that this will be the beach summer of total block, of warmth without tan (see *Nature* **340**, 290–294; 1989). Australians do not lightly forgo such pleasures, which is why some wonder how long-lasting will be the resolve to keep ultraviolet away from skin.

But even in literate Australia, the confusion between the ozone hole and what is strictly the supposed enhancement of the normal greenhouse effect by atmospheric constituents opaque to infrared is as profound as elsewhere. There may be rough justice in that. The springtime Antarctic ozone hole, the reality of which seems well-attested by this season's observations, is at least a sign that a measurable property of the atmosphere is affected by the rate at which unwanted refrigerants are discharged to the atmosphere. If chlorofluorocarbons (CFCs) can affect the ozone layer, why should not the much more copious releases of other greenhouse gases, such as carbon dioxide, affect the climate?

The confusion is nevertheless a threat to good causes, some of which are also green. CFCs are greenhouse gases in their own right (and, molecule for molecule, are more effective than CO_2. But to a first approximation, ozone depletion, whatever its cause, does not affect the climate or even the weather. To a second approximation, of course, ozone depletion (and so CFCs) affect both climate and weather through the changed variation of temperature with altitude — the tropopause is lowered — but the consequences cannot easily be predicted quantitatively let alone disentangled from the data.

How can the distinction between the ozone hole and the enhancement of the greenhouse effect best be established as a part of general knowledge? Much might be done by the direct measurement of the spectrum of solar ultraviolet radiation reaching the surface of the Earth at different places and seasons. The most obvious practical impediments are those of calibration, which, in the absence of data from the past, must necessarily be absolute. Even so, it is remarkable that so little has so far been said about the flux of ultraviolet light reaching the surface of the Earth in even recent years. Paradoxically, if it were shown that ozone depletion means extra ultraviolet, it would be easier to separate that from the direct enhancement of the greenhouse.

While there should by now be no doubt that the next practical step should be the negotiation of an international convention to restrict the release of all greenhouse gases, the more obdurate impediments to understanding and prediction remain as obdurate as ever. It is maddening that the big uncertainties seem to change only slowly with the passage of time. Two stand out. The climate models can incorporate what is called average cloudiness, but the effect of real clouds, with real edges, on the heat balance in the troposphere could be qualitatively different. In principle if not in magnitude, the uncertainties are like those of estimating the role of clouds in nuclear winter (see *Nature* **318**; 99; 1985). That must remain a problem.

The other big uncertainty, at least so far as the greenhouse enhancement due to CO_2 is concerned, remains that of knowing the fate of whatever fraction of the atmospheric content is dissolved in the oceans every year. Increased conversion to inorganic carbon would be benign, solution as bicarbonate in a steadily deepening layer of warm water above the oceanic thermocline would be the opposite. That issue has been endlessly discussed, but there are few who at this stage would put their hands on their hearts and say they know the quantitative truth.

Even relatively operational questions, that of the movement of CO_2 within the oceans for example, are unresolved. That is nicely illustrated by an attempt last year, by Peter G. Brewer and Catherine Goyet of the Woods Hole Oceanographic Institution and David Dyrssen of the Chalmers Institute of Technology at Gothenburg, to measure the northwards flux of CO_2 in the North Atlantic (*Science* **246**, 477; 1989). The North Atlantic is usually supposed to be a substantial sink for the gas, which is supposed to be carried northwards by oceanic currents. But measurements across the Florida Gulf and at three stations along the 25th parallel in mid-Atlantic lead to the conclusion that while there is a substantial northerly transport, that is almost but not quite offset by transport in the opposite direction. The net northwards flux, at 260 million tonnes a year, is just over one per cent of the flux in either direction, or just under 5 per cent of the annual production of this greenhouse gas. This is much smaller than expected.

What can be the explanation? One is that the data may be insufficient. Three sets of measurements of CO_2 concentration with depth are not many, although the authors of the study have used previous survey data to interpolate between their stations. Another is that, while CO_2 will be released as the lower waters of the Gulf Stream reach the surface, it will be reabsorbed from the atmosphere as the Gulf Stream cools, reducing the partial pressure of the gas. Still another is that expectations are not yet fulfilled because there has not been enough time, since the onset of rapid greenhouse gas production half a century ago, for the deep waters of the North Atlantic to have travelled as far north.

In the circumstances, it must plainly be foolhardly to pretend just what the future course of the enhancement of the greenhouse effect will amount to. Better and more measurements will help, although none will be decisive. But if more were known of the variation of CO_2 concentration with latitude in the deep waters of the Atlantic, it might at least be possible to guess when transport into the North Atlantic atmosphere would become substantial. That would provide a means of telling just how quickly the international convention must be negotiated and brought into effect.

Questions such as these were plainly in the minds of some of those attending last week's meeting in the Netherlands, one of several meetings planned as preparation for the more formal diplomatic conferences to be held next year. Governments such as the British were pilloried, but unfairly, for having asked that the details of a convention — the date at which the further accumulation of greenhouse gases should be halted, for example — should await further study. That, of course, is entirely sensible. It is in nobody's interests that the economic disruption an international convention will certainly bring should be accelerated. It is not that there is nothing else to talk about, the demand on behalf of developing countries for fair shares in any quota system there may be for one thing.

John Maddox

IMMUNOLOGY

Tolerance: a second mechanism

Anthony L. DeFranco

A CENTRAL problem for the immune system is distinguishing foreign invaders from the body's self-components. Recognition of the former concentrates the destructive mechanisms of the immune system on the infectious organism; mistaken recognition of the latter results in autoimmune disease. On page 385 of this issue[1], Goodnow and co-workers report that immunological tolerance to self can be induced in mature B cells, thereby giving us good reason to think that tolerance involves at least two principal mechanisms.

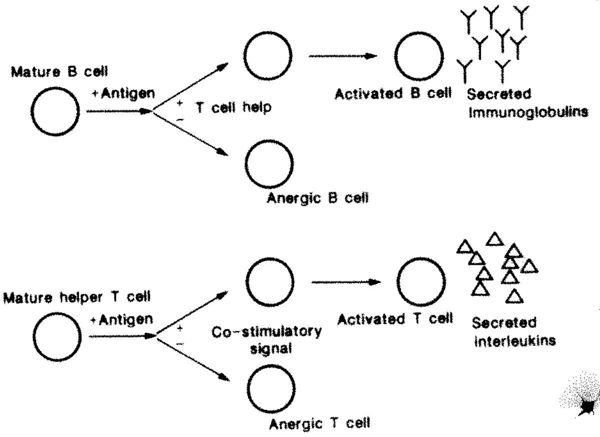
Discrimination between self and non-self can arise from a developmental switch in the response of lymphocytes to antigen: contact of antigen with the antigen receptor on immature B or T lymphocytes induces either death of the cell ('clonal deletion') or long-lasting unresponsiveness ('clonal anergy'). One problem with understanding how this mechanism could be fully responsible for immunological tolerance to self is that lymphocytes develop in limited anatomical locations (bone marrow for B cells and thymus for T cells), but once mature they circulate throughout the body. Thus, mature lymphocytes may encounter self-components that were not present at the sites of maturation, and that therefore could not have induced clonal deletion or anergy. An attractive solution to this puzzle is that contact with antigen may, under some circumstances, also induce unresponsiveness in mature lymphocytes, and Goodnow *et al.* provide perhaps the clearest demonstration to date of this form of tolerance induction.

We are currently in the third phase of the investigation of immunological tolerance. The first phase, ushered in by the studies of Owen *et al.*[2] with dizygotic twins of cows, established that tolerance is an acquired characteristic. The second phase involved analysis of tolerance at the cellular level. These experiments established that unresponsiveness was a property of the antigen-specific lymphocytes, that direct *in vitro* antigen exposure of B cells could induce unresponsiveness, and that clonal deletion or anergy was most easily achieved with immature B lymphocytes[3]. Less was known about tolerance of T cells, because it was harder to follow their activity. A great problem of the second phase was that antigen-specific lymphocytes could not be followed directly. In some experiments, antigen surrogates (such as anti-IgM antibodies) were used to circumvent this problem, but such an approach had inherent limitations.

With the advent of mice expressing transgene-encoded antigen receptors[4-7], and with the discovery that antibodies recognizing the products of certain gene segments ($V\beta$) can distinguish all T cells recognizing certain antigens[8], it is now possible to look at lymphocytes of a given specificity and analyse the effects when they encounter antigen. A great deal has already been learned from these third-generation studies. When immature T cells developing in the thymus encounter antigen and appropriate proteins encoded by the major histocompatibility complex (MHC), the result is clonal deletion[4,5,8]. Similarly, immature B cells expressing immunoglobulin transgenes are inactivated, either by clonal anergy[6] or by clonal deletion[7], if they develop in an animal expressing the antigen. These studies have shown the importance and efficiency of clonal deletion of developing T cells, and have put our knowledge of tolerance induction of immature B cells on a firm basis. In the 1960s, however, it was demonstrated that tolerance could be induced in mature animals, provided that antigen was introduced in the appropriate way (intravenously, for example)[9]. Moreover, it is hard to imagine how components that are apparently expressed only in selected tissues could be delivered to the sites of lymphocyte development in quantities large enough to induce clonal deletion or anergy. Thus, clonal deletion or anergy of immature lymphocytes is unlikely to be the only mechanism contributing to tolerance.

In the case of B cells, the problem of incomplete tolerance can, in principle, be sidestepped. Without the active participation of helper T cells, B cells do not make antibody responses to many antigens, including most self-components[10]. Antibody responses to many bacterial components do, however, occur without helper T cells being involved[10]. If there is a cross-reaction between such a bacterial antigen and a self-component that failed to cause efficient clonal deletion of those B cells recognizing it, then one might expect the production of anti-self antibodies. Indeed, this appears to occur in rheumatic fever, in which antibody produced in response to streptococcal infection cross-reacts with heart tissue, causing tissue destruction.

Goodnow *et al.* now demonstrate[1] that the immune system has a solution to this problem, at least in many cases. They took B cells expressing transgene-encoded membrane immunoglobulin specific for chicken lysozyme and transferred them from an environment lacking lysozyme into a host that expressed lysozyme as a self-component by virtue of a lysozyme transgene. When this was done, mature B cells encountered antigen without antigen-specific helper T cells. The result was that the B cells entered a state of profound unresponsiveness. Moreover, the B cells underwent a phenotypic change characterized by greatly decreased expression of one form of membrane immunoglobulin, mIgM, but continued expression of another form, mIgD. Goodnow and co-workers had previously shown[6] that if the immunoglobulin transgenic B cells developed in a lysozyme-expressing mouse, then the B cells underwent clonal anergy, and showed the same phenotypic change described above. Surprisingly, there was no apparent difference between encountering antigen as immature B cells and encountering it as mature B cells. From previous work, one would have expected a considerable difference in the amount of antigen required to induce clonal anergy, with less needed for immature cells. If B cells with low amounts of mIgM and high amounts of mIgD have all undergone clonal anergy, either as immature B cells or as mature B cells, then this is a common fate, as Goodnow *et al.* report[1] that a



A second mechanism for immunological tolerance. Many (but not all) lymphocytes that recognize self-components are inactivated if, at an immature stage, they come into contact with antigen. Lymphocytes that mature without this happening may come into contact with self or foreign molecules through their antigen receptors, which leads to cellular proliferation and immune responses (antibody secretion, interleukin secretion and so on) provided appropriate second signals are also received. For B cells, such second signals can come from helper T cells (in the form of interleukins) or, in the case of T-cell independent antigens, probably from macrophages. For helper T cells, the antigen-presenting cell (typically a macrophage, B cell or dendritic cell) provides a 'co-stimulatory signal' which is as yet unknown. In either case, if mature lymphocytes come into contact with antigen in the absence of the second signal, the cell enters a prolonged period of unresponsiveness.

considerable fraction of normal splenic B cells have this phenotype.

Thus, antigen-induced unresponsiveness of mature B cells could be an important mechanism for decreasing autoantibody production. Previous studies have demonstrated that clonal deletion or anergy of immature B cells acts on higher affinity B cells but not on lower affinity B cells[11]. If the same is true of clonal anergy of mature B cells, then the only B cells capable of producing autoantibodies would be those of low affinity. Most of the time such low-affinity antibodies are probably not destructive, although there may be exceptions, such as the autoantibodies produced in rheumatic fever.

Mature helper T cells can also become unresponsive on coming into contact with antigen. There are now several reports of situations where the immune system tolerates allogeneic class II MHC molecules (which are recognized by helper T cells) introduced by grafts or tissue-specific expression of a transgene[9,12,13]. Clonal deletion of immature T cells probably cannot operate on T cells recognizing allogeneic MHC molecules unless those molecules are expressed on cells in the thymus (see ref. 9). So acceptance of these tissues probably occurs in the presence of helper T cells that can recognize the antigen[9,12,14]. Similarly, adult Mls-1^b mice made unresponsive to Mls-1^a spleen cells were found to have normal numbers of helper T cells recognizing Mls-1^a, as detected with anti-$V\beta6$ antibodies[15]. The T cells from unresponsive mice were atypical in that they did not proliferate or secrete interleukin-2 in response to stimulation with Mls-1^a spleen cells *in vitro*. Thus, it would appear that unresponsiveness is accompanied by antigen-specific helper T cells existing in an anergic state.

Why do these mature helper T cells fail to initiate graft rejection? One possibility is that the cells recognize antigen in such a way as to induce clonal anergy rather than clonal reactivity. Moreover, tolerance induction of mature helper T cells would go a long way towards explaining tolerance to self-components with restricted tissue distribution, and such a phenomenon has been observed *in vitro* with cloned helper T cells. If these T cells encounter their antigen–MHC complex in a sterile setting, for example in artificial planar membranes or on the surface of lightly fixed antigen-presenting cells, then a profound state of unresponsiveness to antigen is induced[16]. Interestingly, such cells proliferate vigorously on addition of the growth factor interleukin-2, raising the possibility that anergy may be a reversible state. The difference between induction of anergy and induction of a positive response, including lymphokine secretion, is the provision of a second signal (currently unknown) by the antigen-presenting cell.

One thing that remains unclear is what determines whether or not the antigen-presenting cell delivers the second signal to the helper T cell. Recently, transgenic mice were created in which expression of the I–E class II MHC molecule was restricted to the pancreas and kidney[12]. The mice did not reject these tissues immunologically, but the presence of reactive helper T cells could be demonstrated on removal and analysis *in vitro*. This could be an example of clonal anergy induced in mature T cells. In agreement with that idea, I–E-expressing cells from the pancreas were able to induce unresponsiveness in helper T-cell clones, *in vitro*[17]. Perhaps the pancreatic cells lack the capacity to provide the second signal needed by the helper T cells to respond. This suggests that helper T cell recognition of antigen plus MHC on tissue cells may lead to unresponsiveness, whereas more specialized antigen-presenting cells (macrophages, dendritic cells or B cells) may be needed to induce activation.

More experiments will be needed to establish whether the clonal anergy seen *in vitro* with helper T-cell clones is also important *in vivo*. Experiments with transgenic T cells, following the strategy employed by Goodnow *et al.* with B cells, would be one approach. MHC alloantigen expressed on selected tissues may not be a good model for tissue-specific antigens, however, and more experiments are needed with non-MHC antigens expressed in a tissue-specific manner (as has been done with transgene-encoded SV40 T-antigen[18]).

It may be apparent to the reader that there is an underlying similarity between antigen-induced unresponsiveness of cloned helper T cells and that of B cells. In both cases, there are two possibilities for the cell that encounters antigen. In the presence of a second signal coming from a helper T cell or from an antigen-presenting cell, the cell becomes activated; in the absence of the second signal, the cell becomes anergic (see figure). Antigen contact is never neutral. Everything is friend or foe, and the second signal is used to identify the foe. The idea that antigen in the absence of a second signal induces unresponsiveness was originally advanced to explain tolerance nearly 20 years ago by Bretscher and Cohen[19]. The experiments have finally begun to catch up with them. ☐

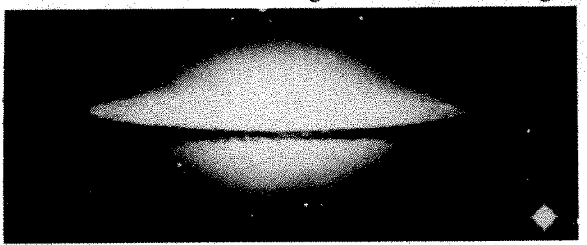
ASTRONOMY

Galactic disk loses weight

M. G. Edmunds

ASTRONOMERS are so embarrassed these days by finding evidence of hidden mass almost everywhere they look, that it is a refreshing change to read a triplet of papers[1] that implies that, although the existence of dark matter in galaxies still seems inevitable, it is no longer necessary to invoke its presence as a major constituent of the disk of our own Galaxy.



Sombrero galaxy with dense, bright disk and inner spheroid.

The dynamics of stars and gas in the Galaxy are governed by its gravitational field, the structure of which is set by the distribution of mass. Three major components of mass can be identified. From visual and radio observation we know a great deal about the disk of stars and interstellar gas, which rotates inside a spheroid of stars (see figure). The third, invisible, component is the corona (sometimes called the dark halo) whose presence is inferred only by its gravitational influence on the rotation of the disk.

By looking out parallel to the galactic rotation axis from our peripheral position in the galactic disk, one sees a change in number density and velocity dispersion of stars as a function of distance from the plane, which can be used to investigate the gravitational field. The greatest influence in this direction is the mass in the disk. In contrast, the variation of rotation velocity in the disk with distance from the centre (the rotation curve) is dominated by the spheroidally distributed mass of the spheroid and corona.

Kuijken and Gilmore[1] have extensively modelled the stellar density and velocity data perpendicular to the plane, to arrive at a value for the integrated surface mass density in a column through the galactic disk at the Sun. The mass in the disk determined in this way (by the dynamics of stars perpendicular to the galactic plane) is sometimes known as the Oort limit, after the pioneering investigations[2] of the Dutch astronomer Jan Oort. Other investigations have indicated about 50 per cent more mass detected dynamically than could be seen in stars or gas. The new work fits models to the data in a rather more general way, and also takes account of the (previously neglected) effect of the increasing influence of the spheroidal gravitional field on stars that reach high above the plane. A correction is also applied in estimating the number of stars at different heights to take account of the effects of chemical composition of stars on their brightness. Because stars that are far from the disk have, on average, a lower abundance of heavy elements than those close to the disk, neglect of this difference could lead to systematic errors in estimating distances and space densities.

The result of the investigations is a local surface density of 46±9 solar masses per unit area (square kiloparsecs) of disk. This is considerably smaller than previous values. The authors give an estimate in the same units of visible matter in the disk as 35±5 for stars and 13±3 for gas. This totals 48±6, in excellent agreement with the dynamical mass. Thus, although some 10 units of dark matter could still be lurking in the disk without offending the error limits, the importance of this investigation is that it implies there is no need to invoke any dark matter in the disk.

The low limit on disk mass has other implications. The rotation curve from the Galactic Centre to about 50 per cent beyond our radius from the centre is reasonably well determined and can be explained only if there is a dark massive corona. Models have been constructed that try to dispense with the corona but still account for the rotation curve by putting as much mass as possible into the disk and visible spheroid — so called 'maximal disk' models[3]. The new local disk mass limit means that the disk itself cannot be massive enough. Although still not constrained as much as some people would like to believe, the visible spheroid probably cannot provide sufficient mass either.

The rotation curve beyond one-and-a-half times our galactocentric radius is less well measured, but certainly implies a dominant distribution of mass unlike that of the spheroid. The reasons for the uncertainty in spheroid mass are both controversy over its shape, and also because it is difficult observationally to measure its density. The problem arises because there are very few spheroid stars in the local solar neighbourhood where they are overwhelmingly outnumbered by disk stars, although the overall spheroid could still contain a lot of stars in total because of its large volume.

The elimination of dark matter from the disk is a pleasant simplification, because we now have only to worry about the corona, a problem well-known in external spiral galaxies. But the shape and other properties of the corona remain obscure, although Kuijken and Gilmore argue that significant flattening of the corona can be ruled out as it would tend to reduce their dynamical estimate of disk mass below that actually visible in stars and gas. One useful additional constraint they point out is that the modelling of dynamics perpendicular to the disk effectively rules out any model that dispenses with a corona and explains the rotation curve by a modification of the law of gravitation to include an extra source of acceleration parallel to the newtonian force. □

PALAEONTOLOGY

Ears and vertebrate evolution

Alec L. Panchen

IN 1987 the members of a highly successful Anglo–Danish expedition returned from east Greenland with about three-quarters of a tonne of rock matrix containing Upper Devonian fossil tetrapods (land vertebrates)[1]. East Greenland is the only area in the world to have yielded tetrapods of this early date (about 360 million years old) in substantial quantities, but most of the material previously collected is attributed to the genus *Ichthyostega*[2]. The majority of the specimens from the recent expedition appear to be of the very different genus *Acanthostega*, which was formerly known only from a handful of specimens. On page 425 of this issue Clack[3], an organizing member of the expedition, describes the stapes of *Acanthostega* in a first account of the new material. She proposes that the stapes in this very early tetrapod was concerned not with the transmission of air-borne sound but with respiratory movements through a spiracle, as in some fishes. This hypothesis adds a further twist to the seemingly endless controversy over the evolution of hearing in tetrapods.

In most living tetrapods the stapes conducts air-borne sound from the tympanum (eardrum) to the inner ear. In three tetrapod groups — frogs, living reptiles and birds — the stapes is inserted in the tympanum and is the only ear ossicle. It is generally agreed that it is the homologue, at least in part, of the hyomandibula of fishes. In fishes, the hyomandibula, a part of a gill arch, serves to suspend the jaw articulation from the braincase on each side of the skull. In mammals, the middle ear contains not one ear ossicle, but a chain of three (stapes, incus and malleus), the last of which is inserted into the tympanum. Discussion of the homologies of these three ossicles started well before the publication of Darwin's *Origin of Species*, when, in 1837, Reichert showed from embryological evidence that the incus and malleus were the homologues of the cartilages that form the jaw joint in all other jawed vertebrates[4]. Reichert's theory was later interpreted in evolutionary terms and is corroborated by evidence from the fossil forebears of mammals[5]. This theory is generally (but not universally[2]) accepted today.

It also seems certain, however, that the nearest common ancestor of mammals on one hand, and reptiles and birds on the other, did not have a tympanic ear. In those fossils believed to be close to that common ancestor (that is, the most primitive amniotes) the orientation of the stapes is like that of the fish hyomandibula from which it was derived, and there are no signs of the characteristic otic notches at the back of the skull that held the tympanum in other early tetrapods. Furthermore, there is evidence that the tympanic ear of frogs evolved separately from that of any amniote[6]. Thus a tympanic ear must have evolved convergently in three unrelated groups of tetrapods — frogs, reptiles and birds, and mammals.

Frogs, and more doubtfully other extant amphibia, are members of a larger group of primitive tetrapods, the temnospondyls. Most fossil temnospondyls have a pair of otic notches at the back of the skull roof and a lightly built stapes directed towards each notch. It is thus probable that they had tympanic ears. But the most primitive temnospondyls, notably *Greererpeton* from the Carboniferous period, had a massive stapes with a skull-bracing function[7]. Clack has shown that another Carboniferous tetrapod, *Pholiderpeton*, which is thought to be related to the amniote line, has a strikingly similar stapes[8]. Both *Greererpeton* and *Pholiderpeton* lack otic notches.

Clack now shows[3] that the stapes of the much earlier *Acanthostega* is of the same type. Yet *Acanthostega* also appears to have otic notches. She suggests, however, that these did not hold tympana, but that each formed the margin of an open spiracle. She further suggests that the stapes was concerned with pumping movements to draw in either air or water through the spiracle for respiration. In fish where the spiracle remains open, notably in skates and rays, the hyomandibula helps to pump water into the buccal cavity; the water is then expelled through the other gill slits. Clack suggests that the stapes of *Acanthostega*, the homologue of the hyomandibula, also had this respiratory function, but probably to ventilate the lungs.

If Clack and her colleagues had not recovered stapes associated with skull material, one might have predicted that the function of *Acanthostega's* stapes was to conduct sound from a tympanum held in the otic notch. Given that three unrelated tetrapod groups are known to have this arrangement, it would have been reasonable to suppose that this was the primitive tetrapod condition and thus would be found in *Acanthostega*. The lack of otic notches, and the massive stapes found in *Greererpeton* and *Pholiderpeton*, could then have been seen as secondary features. The discovery in *Acanthostega* of both massive stapes and otic notches thus forces a re-evaluation of the primitive tetrapod condition that will inevitably affect our ideas about tetrapod phylogeny. ☐

AMAZON DEFORESTATION

Predicting climate effects

Robert E. Dickinson

FEARS that global and local meteorological balances might be upset by the deforestation of the Amazon have made the destruction of the rainforest a matter of wide public concern. Elsewhere in this issue (*Nature* **342**, 411–413; 1989), J. Lean and D. Warrilow describe detailed computer simulations that reveal the impact that might be expected if large tracts of rainforest are replaced by pasture. Most strikingly, they find that rainfall in the region could be dramatically reduced.

The role of tropical forests in the global climate system has long been a subject of speculation. Brazilian studies of the hydrological balance in the Amazon have done much to foster the debate over the past decade. Joint UK–Brazilian micrometeorological investigations are now giving us a much clearer view of the balances of energy and water in and above the forest canopy. But it is only with detailed climate models, such as those used by Lean and Warrilow and also by C. Nobre, J. Shukla and P. Sellers (submitted to *Science*), including representations of the role of vegetation in the water and surface-energy balances, that we can make quantitative estimates of the regional and global changes that may follow extensive deforestation.

As well as predicting a 20 per cent decrease in rainfall over the Amazon region, Lean and Warrilow suggest that the local climate will become warmer and that evapo-transpiration will be reduced. My earlier study with A. Henderson-Sellers and M.F. Wilson (see *Q. Jl R. met. Soc.* **114**, 439–462; 1988), using the National Center for Atmospheric Research community climate model (CCM), also indicated that warming and reduction of evapo-transpiration on a similar scale would follow deforestation, but the model hydrological cycle was too 'noisy' to establish any clear indication of changes in rainfall.

Regional rainfall in the Amazon is highly variable, in both space and time, owing to variations in tropical ocean temperatures. Until climate models can reproduce this variability, projections of changes induced by altered land use will be greeted with scepticism. The hydrological cycle is regarded by many as the weakest component in climate models. The main difference between our earlier study and Lean and Warrilow's is in the numerical treatment of the spatial dimensions, their approach avoiding hydrological difficulties associated with ours. The link the new study seems to have established between rainfall and tropical forests is one of the strongest of its kind yet modelled.

The suggestion of this link increases the urgency with which related questions must be addressed. How do the rainfall anomalies affect weather patterns in the Northern Hemisphere? By analogy with the El Niño–Southern Oscillation phenomena, large-wavelength, transverse 'Rossby' waves in the atmosphere might propagate long-range effects. Will the accompanying changes in ocean temperatures amplify or mitigate the predicted effects? It will be important to find out whether climate changes due to deforestation will act through the forest ecosystem to accelerate the current decline. It may be that the tropical forests are sufficiently stable that they will grow back once human intervention ceases.

The interest in the rainforest reminds us of the other effect of vegetation on climate. Vegetation is a reservoir for carbon that annually exchanges with the atmosphere an order of magnitude more CO_2 than is added by human activity. The loss of the tropical forests is recognized as adding significantly to the increases in atmospheric CO_2. As the political will grows to prevent such increases, it is

100 years ago

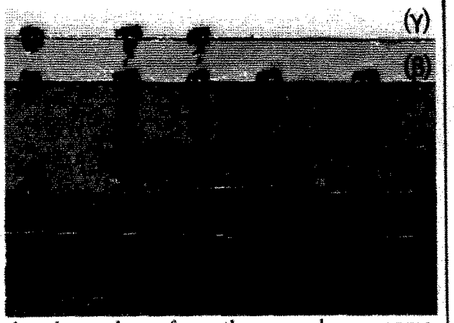
Mirage in the South American Pampas

I WAS staying in the Pampas of the Argentine Republic, near Melincue, a small town of the Provence of Santa Fe, from September 1888 to March 1889. During my stay I had the opportunity of observing certain mirage phenomena. To illustrate my observations I had drawn eight diagrams; but, for the purpose of insertion in *Nature*, I have been obliged to reduce these. Hence I fear that my descriptions may not be as clear as I should wish.

The Winter Mirage.

I saw this mirage several times, always about sunrise and after a frost. There would be, for example, just below, or on the edge of the line (α), a cow. This I will call the *"first cow,"* or the "original cow." Just below or on the line (β), vertically above the *first cow*, and, like it, erect, would be a *second cow*, a repetition of the first. And often, above this again, below or on the line (γ), would be a third cow, also erect.

Sometimes there were confused images hanging from the *second cow* and joining other confused images piled on the *first cow*; sometimes the first cow was clear of images, while



they hung down from the second cow; sometimes the second cow was near, and there were images piled on the first.

The mirage lasted until about an hour and a quarter after sunrise. W. LARDEN

From *Nature* **XLI**, 69–71; November 1889.

worth noting that the cost of techniques for reducing CO$_2$ emissions, up to many hundreds of dollars per tonne of carbon removed, probably outweighs any economic benefit gained from forest destruction. It is easy to imagine that the path with least initial cost to reduce CO$_2$ inputs to the atmosphere would be in the form of payments to countries with tropical forests for a reduction in cutting and burning.

The many political, social and ecological factors behind tropical deforestation make this a complex issue. But although studies of the climatic impact of deforestation will help climate modellers understand the important features in the weather system, it is questionable that they will help policy makers in tropical countries tackle their ecological problems. ☐

MID-OCEAN RIDGES

Mixing of basalt magmas

Emily M. Klein

THE pressure at which melting and melt segregation occur to produce mid-ocean ridge basalt (MORB) magmas is at the heart of a long-running controversy. This is due to the fact that from the pressure one can constrain physical characteristics of divergent plate boundaries, such as the temperature structure beneath the ridge axis or the width of the melting zone, and chemical characteristics of the primary magmas in equilibrium with the mantle source. Some argue[1] that primitive MORBs represent nearly primary magmas in equilibrium with the mantle at pressures as low as 7 kbar, corresponding to a relatively shallow depth, 21 km, beneath the ridge axis. Others suggest[2] that extensive crystallization *en route* to the sea floor has substantially modified the primary melt that was generated at pressures of 15–30 kbar (45–90 km). Although the two schools may seem irreconcilable, Salters and Hart, on page 420 of this issue[3], contribute to a growing body of evidence suggesting that advocates of both extremes may, in fact, be correct, united under a more realistic model for the melting process beneath ocean ridges.

In their study, Salters and Hart examine Lu–Hf and Sm–Nd isotope and trace-element systematics in MORB and ocean-island basalts. The authors identify a discrepancy between the measured parent-to-daughter trace-element ratios of Sm/Nd and Lu/Hf, on the one hand, and their isotope ratios ^{143}Nd/^{144}Nd and ^{176}Hf/^{177}Hf, on the other. The observed isotope ratios are 'unsupported' in the sense that the high ratios imply parent-to-daughter trace-element ratios higher than observed. For the Lu–Hf system, the authors term this discrepancy the Hf-paradox and explore the possibility that the decoupling between trace-element and isotope ratios occurs during the melting process itself.

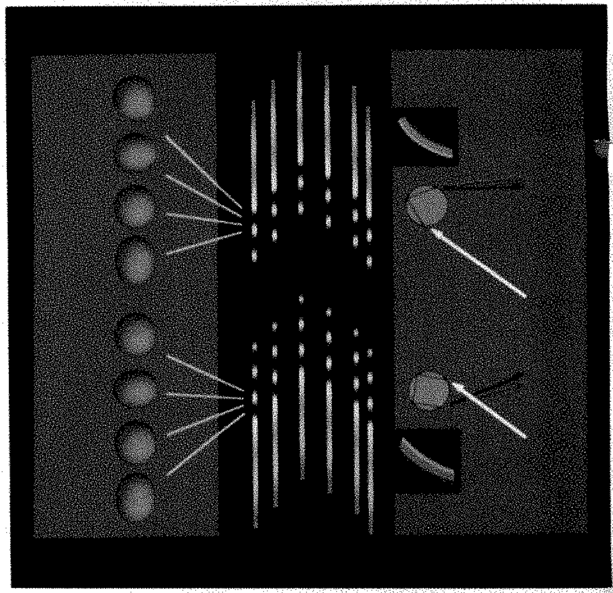
Specifically, if garnet is a residual phase during the melting process beneath the ocean ridge, the greater chemical affinity of garnet for Lu than for Hf will lead to low Lu/Hf ratios in the melts produced within the garnet stability field. The stability of garnet as a residual phase in turn implies that a significant portion of the melting process occurs at pressures greater than about 20 kbar, where garnet replaces spinel as the stable aluminous mantle phase.

Salters and Hart adopt a more realistic melting model that recognizes that if melting occurs by adiabatic decompression, it must be polybaric, with melts generated (and segregated) over a range of pressures beginning deep within the garnet stability field and extending to lower pressures within the spinel stability field. The basaltic magma erupted at the ridge axis thus represents an average composition generated by the pooling of melts from throughout the polybaric melting column. From this perspective, advocates of high- or low-pressure melting are both correct in the sense that melting occurs over a range of pressures. It is important to recognize, however, that for a pooled melt composition, the concept of a single pressure of equilibration during melting, as implied in the earlier studies, has no meaning.

Studies of the major-element compositions of MORB also support the concept of a polybaric melting column and the conclusion that for the majority of MORB magmas, melting begins at high pressures (20–40 kbar). Examining the range of major-element compositions observed among regional averages of MORB chemistry, Langmuir and I noted[4] that parameters indicative of the extent of melting, such as sodium content or the ratio of calcium to aluminium, correlate with parameters indicative of the pressure of melting, such as iron or silica.

As with the Lu–Hf systematics, this relationship can most easily be understood in terms of the pooling of melts from throughout polybaric melting columns; the height of each column is governed by the solidus pressure and therefore the mantle temperature beneath the ridge axis for a given region. The observed correlation between the extent of melting and pressure of melting results from the fact that the deeper the intersection of the mantle solidus, the greater the proportion of melt generated at high pressure and the greater the total amount of melting achieved. Indeed, Salters and Hart note the complementary nature of the major-element, trace-element and isotope data and observe that their indicator of the pressure of melting, δ(Lu/Hf), correlates

Rainbows reveal good vibrations



How big is a raindrop? One way to find out is to use radar. Air pressure flattens falling drops, more so for larger drops, the oblateness being detectable with polarized radar beams. But, as Kenneth Beard and colleagues point out on page 408, oscillations of the raindrops, by averaging effects can make them seem smaller. This effect becomes noticeable for drops 1–1.5 mm in diameter, possibly owing to a resonance between the natural frequency of drops this size (a few hundred hertz) and the frequency with which air eddies in the wake are shed. To test this hypothesis, Beard *et al.* observed the changing rainbow reflections of white light scattered by each drop as it fell. Lamp and detector are arranged to favour red light reflections. As the drop oscillates, either yellow or infrared (dark) light is preferentially reflected, leaving a characteristic pattern on streak photographs of the falling drops, as depicted above (top, primary rainbow; bottom, secondary). ☐

with major-element indicators of the extent of melting, such as sodium.

The idea that the generation of MORB involves the pooling of melts is also supported indirectly by a study of Sr, Nd and Pb isotopes in basalts recovered from near-ridge seamounts and their adjacent ridge segments, reported by Castillo and Batiza in *Nature* last week[5]. Previous studies of the East Pacific Rise axis and adjacent seamount isotope systematics have shown that, although the two environments overlap in isotope composition, the isotope diversity of the seamount lavas is considerably greater than that of the ridge-axis lavas[6]. The proximity of the ridge and seamounts suggests a similar mantle source, composed of dispersed, isotopically heterogeneous mantle material.

The greater isotopic diversity of the seamounts may therefore result from the sampling of isotopically distinct reservoirs and eruption of the distinct magma compositions, while the greater homogeneity of the ridge-axis magmas may result from the pooling of these isotopically diverse melts before eruption. This interpretation is easy to fathom for the fast-spreading Pacific ridges, where robust magma supply and the presence of a subaxial magma chamber[7] can be expected to foster homogenization of diverse melt compositions.

Castillo and Batiza show that the relationship observed in the Pacific also holds for seamounts and the adjacent segment of the mid-Atlantic ridge in the South Atlantic. This is despite the fact that the spreading rate of the southern mid-Atlantic ridge is one-quarter that of the East Pacific Rise, that magma supply is presumably less voluminous, and that evidence of a steady-state magma chamber to facilitate homogenization has yet be documented. Nevertheless, the isotope study of Castillo and Batiza suggests that significant mixing of isotopically distinct melts occurs even beneath the mid-Atlantic ridge, attesting to the homogenization of melts even at slow spreading rates. Although it is not clear where this homogenization process is taking place, whether in magma conduits or perhaps in small, ephemeral magma chambers, there is now a substantial body of evidence from isotopes, trace elements and major elements that MORB-magma genesis involves the pooling of melts from a heterogeneous mantle over a wide range of pressures. ☐

ARCHAEOLOGY

Age and the female form

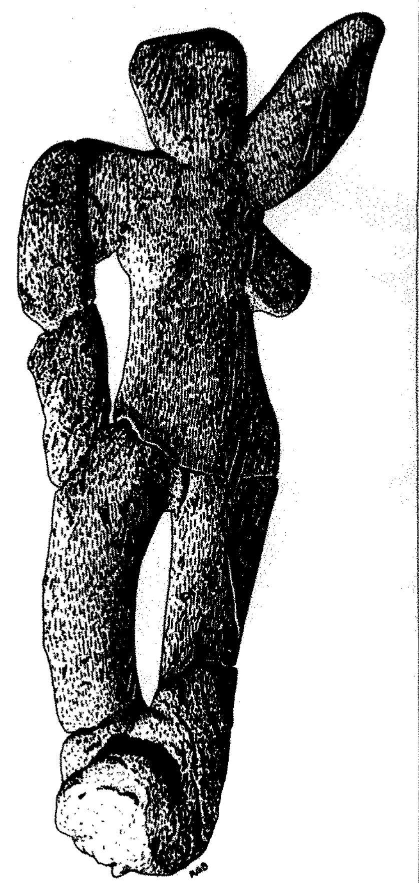
Paul G. Bahn

ARCHAEOLOGISTS in Austria have discovered one of the world's earliest known sculptures, in the form of the oldest dated female figurine[1]. The find is remarkable not merely for its antiquity but also for the artistic sophistication it displays.

Since 1941 the loess sediments of the Galgenberg site, near Krems, have been known to contain bones of Ice Age mammals (including reindeer and mammoth) together with abundant charcoal and flint flakes. New excavations in a nearby vineyard, directed by Christine Neugebauer-Maresch for the Österreichisches Bundesdenkmalamt, led to the discovery in September 1988 of the fragments of the female figurine. Charcoal samples from the same layer have produced radiocarbon dates of 29,200 to 31,190 years before present (BP).

The 'Dancing Venus of Galgenberg', as the sculpture has been dubbed, is 7.2 cm long, and carved in green serpentine. Unlike the well-known 'Venus figurines' of the Ice Age, such as that from Willendorf in Austria (found almost exactly 80 years earlier to the day), the Galgenberg specimen is flattish rather than carved in the round; its shape was probably predetermined by the stone used, because serpentine often occurs in slabs. The figure has not been polished, and its surface shows the marks of tools and erosion.

The right arm and the legs are supported at both ends, while the left arm appears to be folded back at the elbow. Body weight is supported primarily on the left leg, while the right leg rests on a slightly higher support. The right hand is placed on the hip. This pose causes the left breast to be depicted almost in profile, while the right is in very low relief because of the stone's flatness. The vulva is marked (a feature rare in Ice Age depictions of females[2]), and in further contrast to many of the better known 'Venus figurines' there is no hint of obesity or of an emphasis on breasts and buttocks. The figure is more or less anatomically accurate, except for the thickened limbs which are probably as thin as the artist dared carve them without making the sculpture unduly fragile.



The 'Dancing Venus of Galgenberg', which is some 30,000 years old. The sculpture is 7.2 cm long and is carved from green serpentine stone. (Drawing by R. Bednarik, from a photograph.)

There are two important points about the Galgenberg figurine. First, it is at least 5,000 years older than the 'Gravettian period' to which most 'Venus figurines' are usually, often unjustifiably, assigned; most of the Western European specimens have no archaeological context whatsoever, and are merely assumed to be Gravettian[3], whereas dated specimens in Eastern Europe in fact span a period from about 23,000 to 12,000 years BP[4].

Second, the Galgenberg carving is the result of considerable technological skill — the stone is rather delicate and brittle, and the head, left arm and breast could all easily have broken off. In addition, the two openings (under one arm and between the legs) would have required a delicate boring operation; the later 'Venus figurines' are normally static, solid symmetrical figures with no perforations and no protruding limbs[5].

The sophistication revealed in both technology and composition can only be the end-result of a long tradition in carving (perhaps of perishable materials). The same conclusion had already been reached from study of the contemporary or even older ivory carvings of animals and humans from West Germany (Vogelherd, Geissenklösterle, Hohlenstein-Stadel)[6] and perhaps also the ivory human figurines from Brassempouy in France[7].

These objects, the oldest figurative carvings known at present, simply cannot represent the 'first art', which must therefore have appeared long before.

In this respect, the Acheulian female 'figurine' from Berekhat Ram, Israel[8] may provide a crucial clue. Dating to between 230,000 and 800,000 years BP, it is a small scoria pebble whose shape, naturally resembling a 'Venus figure', may have been modified by several grooves. Whether or not it was modified, its very presence at Berekhat Ram implies that the occupants of the site recognized its iconic properties, and therefore that an interest in the female form is one of the most enduring features of mankind. ☐

CHEMICAL PHYSICS

Size-selected solvent cages

Tony Stace

AN isolated diatomic molecule photoexcited to an electronic state above the dissociation limit will swiftly break up into free atoms (Fig. 1). In a liquid or dense gas, however, the relative kinetic energy of the excited atom pair is often lost to a surrounding solvent cage before it can separate. This is the cage effect, first proposed by Franck and Rabinowitsch[1] to explain the reduced photochemical yield, ϕ, of free radicals (atoms or molecular fragments with an unpaired electron) in solution. Attempts in liquid-phase experiments[2] to reveal details of the process at a molecular level are impeded by the bulk physical properties of the liquids. In an effort to resolve this problem, Lineberger and colleagues[3] have studied the dynamics of atom recombination (caging) in mass-selected cluster ions.

Small clusters comprising a chromophore, I_2^- (which absorbs light at a wavelength of 720 nm) and 1–20 carbon dioxide molecules in the form $I_2^-.(CO_2)_n$, generated in a vacuum at the entrance to a mass spectrometer, are mass-selected and excited by a pulsed dye laser. Depending on the value of n, this induces either of the following photofragmentation steps:

$$I_2^-.(CO_2)_n \xrightarrow{\text{light}} I^-.(CO_2)_m + I + (n-m)CO_2 \quad (1)$$

$$\xrightarrow{\text{light}} I_2^-.(CO_2)_k + (n-k)CO_2 \quad (2)$$

In reaction (1), I^- has photodissociated in much the same way that it might as an isolated gas-phase species. But as n increases, there is a tendency for reaction (2) to dominate: under those circumstances, the CO_2 molecules are operating as an effective cage. They absorb the kinetic energy of the separating fragments, and dissipate it by being evaporated from the cluster[4]. Provided the energy of I_2^- falls below the bond energy for the ground state (Fig. 1), the molecular ion is stabilized and cannot dissociate. Plotted in Fig. 2 is the product fraction resulting from reaction (2) as a function of cluster size; in effect, the graph is a plot of $1 - \phi$. As might be expected, increasing the size of the cluster increases the probability of caging. In previous experiments, Lineberger's group[5] showed that, for a given size of cluster, the photofragment yield, ϕ, increases with photon energy.

Since the early work by Franck and Rabinowitsch[1], there have been many attempts to characterize the cage effect in terms of both timescale and molecular or solvent parameters. These efforts were limited by the fact that it was not possible to monitor the influence of a single solvent variable: changing the solvent molecular mass invariably leads to a change in solvent size and/or viscosity. But about 15 years ago Troe and co-workers[2] used simple solvents, such as condensed inert gases, to allow a more systematic variation of parameters; thus a change from liquid argon to liquid xenon gives a considerable difference in mass, but not in viscosity. Also, the photochemical yield could be monitored as a function of gas pressure. In this way, Troe and colleagues spanned the complete range of behaviour, from low pressures for which $\phi \simeq 1$, through to very high pressures (10,000 atmospheres) where little or no photodissociation was observed.

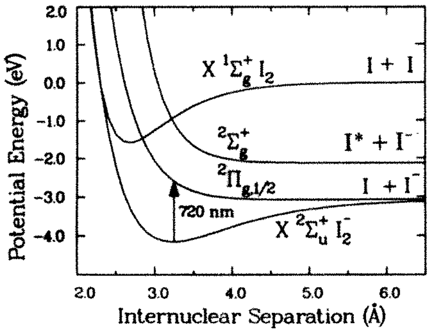

FIG. 1 Approximate potential-energy curves for I^- and I_2. In the clusters the $^2\pi_{g,1/2} \leftarrow {}^2\Sigma_u^+$ transition between the bound ground state and a low dissociating state is excited with 720 nm laser radiation.

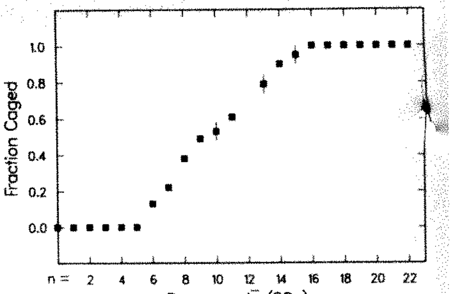

FIG. 2 Fraction of products resulting from reaction (2) as a function of cluster size, *n*, following the photoexcitation of $I_2^-.(CO_2)_n$ with laser radiation of wavelength 720 nm. (Lineberger *et al.*, unpublished results.)

As might be expected, dense Xe, N_2 and CO_2 act as relatively efficient cages, whereas He and Ne do not. At the same time, picosecond (10^{-12} s) time-resolved measurements of the photodissociation of I_2 in liquid by Chuang *et al.*[6] greatly elucidated the dynamics of the caging process. In particular, they led to the development of models for caging based on a diffusion-controlled recombination of geminate (original) pairs.

The current experiments by Lineberger and co-workers can be seen as a natural step forward from both these techniques. The group seeks to take an individual localized environment, as seen by the excited molecule or ion, and establish how effective it is at promoting a cage event. The latest experiments are time-resolved, and yield a measure of how quickly ground-state I_2^-, in reaction (2), recovers its original electronic and vibrational state. The measured time, just 10 ± 5 ps for $I_2^-.(CO_2)_{16}$ (about 500 CO_2 vibrational periods), is a convoluted response derived from both the experimental situation and instrumental parameters.

On a picosecond timescale, there are several factors associated with the physics of photodissociation and recombination that could influence events: curve-crossing (electronic-to-translational energy exchange) from the excited electronic state to the final ground-state; vibrational relaxation of the ground state (the electronic absorption profile of I_2^- will change according to its vibrational energy content); and the possibility of recombination into one of several low-lying electronic energy states (a complete description of the electronic states of I_2^- is more complex than that given in Fig. 1). Taking into consideration the results depicted in Fig. 2, one might conclude that it requires 12 or more molecules to establish an effective cage, and that under those circumstances, recombination of the iodine atoms is very rapid.

In a liquid, a small chromophore such as I_2^- could have between two and ten immediate neighbours, depending on the size of the solvent molecules. Therefore, the cluster results support the view that

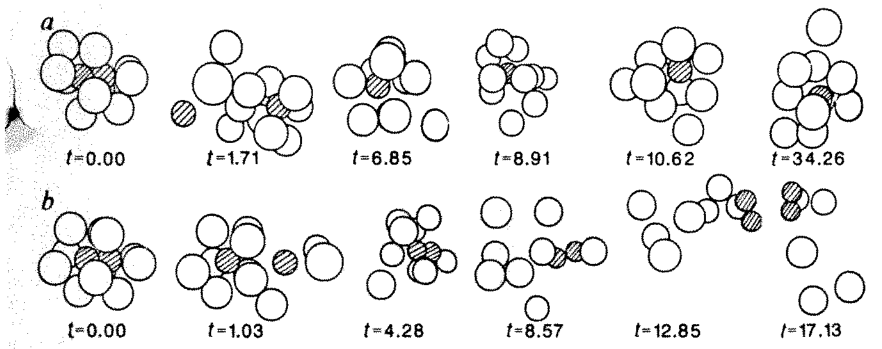

FIG. 3 Results of a computer simulation[7] of events which immediately follow the photoexcitation of $Br_2^-.(CO_2)_{11}$; the bromine atoms are shaded. *a*, The Br_2^- photodissociates; *b*, the cage event leads to the cluster losing most of its carbon dioxide molecules. (Time, *t*, in picoseconds.)

liquid-phase caging[6] is a fast, localized phenomenon, and that most events are probably geminate processes. But a direct extrapolation from cluster to liquid is not necessarily valid: energy flow from a cluster is an irreversible process that has no liquid-phase analogue[3].

Parallel to the experimental progress has been the development of theoretical techniques designed to simulate the caging process at a molecular level[2]. Many of these have evolved from advances in the computer simulation of simple liquids. As one might expect, it is easier to simulate liquid argon than it is liquid benzene or hexane, so that the experiments of Troe and co-workers[2] have provided an ideal source of experimental data. One obstacle associated with the computer simulation of simple liquids remains, namely boundary conditions. The computer, both by virtue of its finite memory and lifetime of the operator, can handle only a limited number of particles — typically 250–1,000 for a physical timespan of about 10^{-10} s. To achieve macroscopic proportions, an 'infinite' three-dimensional lattice is created by defining boundaries that are translated images of the particles under consideration.

The beauty of Lineberger's experiments is that, at least for the simulation of the cage effect, such artificial barriers are no longer necessary. The dynamics of the caging process in a simple cluster, $I_2^-.(CO_2)_n$ or $Br_2^-.(CO_2)_n$, can be followed using numerical techniques to solve Hamilton's classical equations of motion for the complete system. Figure 3 shows two examples where a computer has been used[7] to simulate the sequence of steps which immediately follow the photoexcitation of $Br_2^-.(CO_2)_{11}$ (for the purposes of the present discussion, the behaviour of $I_2^-.(CO_2)_n$ and $Br_2^-.(CO_2)_n$ is identical). At time $t = 0$, the Br_2^- chromophore absorbs a photon which increases the total energy of the cluster by approximately 1.7 eV. The temporal evolution of the cluster is then followed for up to 34 ps, during which time either of reaction steps (1) and (2) can occur. In the simulation depicted in Fig. 3*a* an ion photodissociates, and a Br atom can be seen leaving the cluster after approximately 1.7 ps. In contrast, Fig. 3*b* shows a caging event where the excess energy in the chromophore has been successfully removed, but at the expense of almost all the CO_2 molecules contained in the cluster. The timescale for the latter, 17 ps, is in reasonable agreement with that determined by Lineberger and co-workers.

Computer techniques are available that allow simple molecules, such as N_2 and CO_2, to be treated as structured, rigid, rotating molecules in simulations of this type[8]. Although such a step might seem attractive, it may not help clarify caging. An important relaxation mechanism must be the exchange of energy from the vibrational modes of the excited chromophore to the vibrational modes of the molecules in the solvent cage. Treating the cage molecules as rigid rotors excludes such an exchange. But computer simulation techniques are a long way from being able to treat collections of vibrating molecules. To some extent, the ball is still in the experimentalist's court; theorists now need results for $I_2^-.Ar_n$ or $I_2^-.Kr_n$. □

DNA FINGERPRINTS

Victims or perpetrators of DNA turnover?

Gabriel A. Dover

As revolutions go, the discovery of restless minisatellite DNA families (the basis of DNA fingerprinting in humans)[1] is here to stay; and as with all good revolutions it has incited the search for other unruly sequences. As the evidence emerges, it seems that human minisatellite DNA is at the tip of an iceberg of many types of more passively fluctuating repetitive sequences.

It was no accident that Jeffreys called regions of hypervariable length fluctuations 'minisatellite' DNA, because of their similarity in organization to the large blocks of maxisatellite DNAs. The ease of isolation and sequencing of maxisatellites quickly gave investigators a panoramic view of a landscape seemingly populated by every conceivable type of satellite DNA, in terms of repeat-unit length (2–2,000 base pairs (bp)), sequence composition, copy number and chromosomal distribution. Are minisatellites as diverse and bewildering as the maxisatellites and multigene families?

The first analysis of human minisatellite repeating units exposed a conserved 'core' sequence with similarities to the *chi* recombination signal in *Escherichia coli*[1] and probably serving as a hotspot for meiotic unequal crossingover[2]. Is this sequence an obligatory constituent within all DNA families showing hypervariability in copy number? Or are there many (possibly thousands) of repeated DNA families wildly fluctuating as a consequence of unequal crossingover and alternative DNA turnover mechanisms such as slippage, rolling circles, and those responsible for telomeric growth, which seemingly do not require *chi*-like sequences? With a nod to the 'selfish DNA' debate of the innocent early 1980s, we can ask if hypervariable minisatellites are constitutionally selfish or blissfully ignorant?

From comparisons of core sequences of the several minisatellite DNAs listed in the table (see ref. 3 and references therein) it could be that the conserved core sequence (GGCAGGAXG) (dashed underline in the table) found by Jeffreys is not widespread, and, given the G-rich composition of the majority of sequences being compared, the statistical meaning of the one remaining common sequence G-----GG (underlined) is not entirely convincing. Not only is this relic similarity even further removed from the core sequence, but it also places doubt on its functional relationship (if any) to the *chi* recombination signal (GCTGGTGG). Moreover, other AT-rich minisatellites, derived from the apolipoprotein B gene and the collagen type II gene, do not share any core homology with G-----GG or *chi*.

In similar vein, hypervariable length variation within exons can be due both to repeats containing *chi*-like sequences (as in the silk-moth chorion genes[4]) or repeats not containing *chi*-like sequences (as in the human proline-rich protein genes[5]) (see table). The short length of the repeat (9 bp) in the former indicates slippage, whereas the longer repeat (48–63 bp) in the latter indicates unequal crossingover, as mechanisms of turnover.

The widespread occurrence and high sequence heterogeneity of slippage-generated simple sequences means that a great proportion of eukaryotic genomes have the potential to yield hypervariable arrays that are unique to one or other single locus, a situation of some importance in the application of DNA fingerprinting to population biology. This has been brought dramatically to the fore by the recent exploitation by several investigators, using the polymerase chain reaction, of naturally occurring, simple sequence arrays of GT repeats from humans, CAG repeats from *Drosophila melanogaster* and CT repeats from a whale, as hypervariable single-locus probes for easy two-band individual identification in the respective species (see ref. 6 and references therein). Synthetic oligonucleotides based on non-*chi*-like ACNGGN and TCAGGC repeats from within the *per* gene of *D. melanogaster* and the synthetic $(CAC)_5$ have also been used successfully as fingerprint probes, indicating that simple sequences are a rich untapped source of fluctuating length variants.

It is becoming increasingly clear that eukaryotic nuclear genomes (including extensive regions of exons and control sequences) are largely non-random and repetitive on both a fine-grained and a larger scale[7]. They are played upon by half a dozen sequence-dependent and sequence-independent mechanisms of turnover. To misquote Tolstoy: all families have their ups and downs, but each suffers in its own way.

Furthermore, all the mechanisms of amplification and turnover frequently operate one on top of another. For example, slippage (and micro gene conversions) may often be churning around within human minisatellite arrays at some loci during spermiogenesis[2], and in arrays of the *Drosophila* ribosomal RNA genes[8], generating complex patterns which are uninterpretable using simplistic models of selection or drift which do not incorporate DNA turnover. There are probably few long tracts of randomly organized single-copy DNA marching to the beat of a 'molecular clock'[9]. Minisatellites, whether victims or perpetrators of turnover, are seemingly the tips of icebergs of hundreds of heterogeneous families, tightly packed together throughout most of the genome. Human genome sequencers beware — the going will be tough. ☐

DAEDALUS

Molecular knitting

MANY monomers, like styrene, can polymerize ionically. The incomplete polymer chain terminates in an electric charge; a monomer molecule reacts with it, the charge jumps to the new end, and the action is repeated. So the growing head of the chain carries a charge along with it.

Now a charge moving in a magnetic field travels in a circle. So, says Daedalus, a polymer chain extending in such a field will grow in a circle. The reaction should give that elusive rarity, a closed-loop ring polymer. Random brownian displacements may prevent perfect closure on the first circuit, but sooner or later the growing, winding snake will bite his own tail.

In a dilute solution, individual ring molecules will result. But in strong solutions or pure liquid monomer, the crowded molecular loops will inevitably grow through each other. The result will be a unique 'molecular chain mail' — a three-dimensional lattice of interwoven loops.

Molecular chain mail will have intriguing properties. Pulled in one direction it will shrink strongly in another, like a knitted pullover. It will not melt and will have a fantastic breaking strain, for it can fail only by the shearing of its chemical bonds. Made in a weak magnetic field, it will be soft and flexible, with large, floppy loop molecules; a strong field will give a tough solid with small, tight molecular links. It could even be made totally rigid by 'vulcanizing' it with a few cross links between the loops. Even so, it would not be brittle; for excessive loads would merely shear the cross links. The material would then 'work soften' locally, and yield slightly to relieve the concentration of stress.

More interesting still, molecular chain mail will have strongly nonlinear elasticity. It will yield readily to a small force, but as the molecular loops distort and pull taut, it will increasingly resist further extension. This is the subtle characteristic which gives biological tissues their remarkably high tenacity and freedom from catastrophic failure. It saves arteries, for example, from inflating locally under excessive pressure, and stops a bat's wing from tearing across if it catches on a thorn.

At last synthetic chemistry will be able to rival leather, catgut, sinew and other prized biological materials. Unbelievably pliable and strong, Daedalus's molecular chain-mail polymers will invade the market with a thousand uses, from shoes, handbags and coats to tubing, violin strings and balloon fabrics. And surgeons may welcome them as the ideal artificial material for soft-tissue repairs, fully compatible with the mechanical properties of their living surroundings. David Jones

Transmembrane protein of SIV

SIR—We would like to add to the observations on the transmembrane protein (TMP) of simian immunodeficiency virus (SIV) reported by Hirsch *et al.* in a previous scientific correspondence[1]. Immunoblot analysis of purified virus from a non-cloned pool of infectious SIV_{MAC}, isolated from a rhesus macaque infected with SIV_{MAC251} (virus supplied by R. Desrosiers) demonstrated the presence of a diffuse protein of relative molecular mass 42–46,000 (M_r 42–46K) (Fig. 1*a*). This virus pool, produced by co-cultivation of monkey peripheral-blood lymphocytes with phytohaemagglutinin-stimulated human cord-blood lymphocytes for 17 days followed by growth on the human C8166 T-cell line for 20 days, induces fatal AIDS-like disease in rhesus macaques[2] and is intended for use as a vaccine challenge stock. Further passage of this virus in C8166 cells resulted first in a population displaying proteins with M_r of both 42–46K and 31–37K (Fig. 1*c*) and later a predominance of 31–37K material (Fig. 1*d*). Nucleotide sequencing of polymerase chain reaction (PCR) amplified proviral DNA corresponding to the TMP-coding region of the SIV *env* gene revealed the presence of an in-frame stop codon in all six clones derived from the more highly passaged material, whereas none of the eight clones derived from low passage material contained a stop codon within this region (Fig. 2).

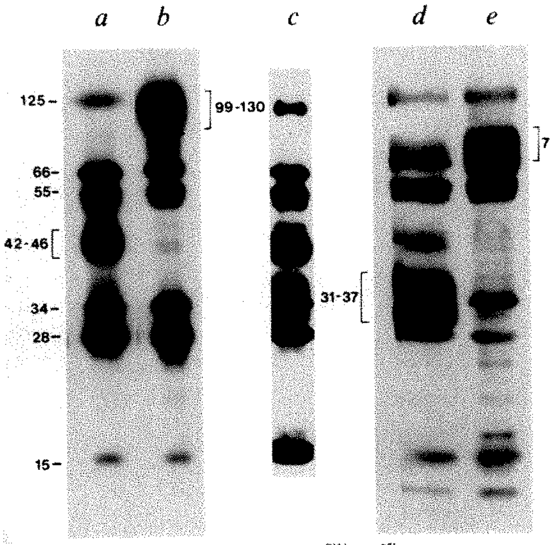

FIG. 1 Virus was purified by ultracentrifugation and chromatography on Sepharose 4b from cultures of infected C8166 cells. The cultures were passed every 3 or 4 days by feeding with uninfected cells in a ratio of 1:3. Tracks *a*, *b*, pass 6; track *c*, pass 14; tracks *d*, *e*, pass 18. Tracks *b*, *e* were applied in sample buffer without SDS. Virus antigen was electrophoresed on 12.5% polyacrylamide gels containing SDS and proteins detected by probing with serum from an SIV-infected monkey followed by ^{125}I-labelled Protein A. Relative molecular masses (K) were estimated from standards.

FIG. 2 Comparison of the DNA and amino-acid sequence of a portion of transmembrane region of the *env* gene of SIV_{MAC}. DNA was isolated from infected C8166 cells at low or high passage. PCR-amplified TMP-coding region was cloned and sequenced by standard procedures and the results compared to those published for two molecular clones of SIV (ref. 6). ▲, Nucleotide change; ■ amino-acid change, ★★★, termination codon.

We then analysed virus-derived antigen for the presence of oligomeric TMP. It has been reported for HIV-1, that heat stable oligomers of TMP may be detected by immunoblotting when SDS concentrations are reduced in the PAGE sample buffer[3]. Both full-length (Fig. 1*a*,*b*) and truncated (Fig. 1*d*,*e*) SIV TMP were found to form such oligomers; the estimated relative molecular masses indicate, in both cases, that these complexes are composed of dimers or trimers or both.

An experimental whole-inactivated-virus vaccine, currently under trial in rhesus and cynomologus macaques contains full-length and truncated TMP (Fig. 1*c*). Because infected animals exhibit antibody responses to peptides from the cytoplasmic C-terminal domain of SIV TMP (ref. 4) and this region modulates growth properties of the virus, at least *in vitro*[5], we believe inclusion of this region in putative vaccines to be important.

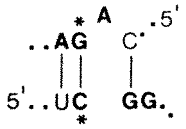
Genetic code origins

SIR—We wish to point out a remarkable circumstance associated with the recent characterization of the guanosine/arginine-binding site in *Tetrahymena* intronic RNA.

F. Michel and colleagues[1], elsewhere in this issue, show that nucleotide pair G264·C311 contributes to the specificity of this part of the catalytic site, and suggest that G264 is hydrogen-bonded to the guanosine/arginine ligands. The remarkable circumstance is that this sidechain- and stereo-selective arginine site[2] is formed by the conjunction of two arginine-encoding triplets, AGA and CGG:



The base pairs marked with vertical bars form the end of the conserved helix, conventionally called P7, and the arginine codons are in bold type. The critical base pair is between the asterisks.

Arginine has six possible codons, and arginine codons comprise 6.1 per cent of the contiguous triplets in the *Tetrahymena* intron. Given an arbitrary choice of two nucleotides, the probability that both lie within a codon for arginine (in any phase) is 0.029. The above observation would not, therefore, be sufficiently rare in itself to imply more than coincidence. In fact, the CGG codon itself is easily dismissed as coincidental. It is not phylogenetically conserved, instead being rather rare among the 66 tabulated group I intron sequences[3].

The AGA codon, however, is different. Although the P7 region is well conserved, there is considerable variation at the AGA codon. Among the 66 group I sequences there are 32 AGA codons (48 per cent), 31 CGA codons (47 per cent), and 3 AGG codons (5 per cent) occurring at the same positions in the sequence. However, these three sets of triplets all encode arginine. Thus, although there is variation on both sides of the completely conserved G264 residue, this variation produces triplets that represent both sets of modern arginine codons, AG^{A}_{G} and CGN.

All self-splicing group I RNA's so far examined have an arginine-binding site at this same location[4]. Sequence variations flanking the G residue that is apparently in contact with site-bound arginine produce three arginine codons and no others. The unbroken prevalence of this pattern in modern RNAs indicates that the sequences at this point must have also been arginine codons in ancient group I RNAs. This supports the suggestion[4] that this specific RNA–amino acid interaction may have been a progenitor of the genetic code. The code, on this basis, probably developed from an ancient RNA codon–amino-acid interaction, as somewhat originally suggested by Woese[5].

Homoeopathic test

SIR—The practice of homoeopathy depends on the use of medicaments prepared in a special way. Solutions derived from a variety of parent substances are progressively diluted, with a dilution factor of 1 in 100 at each stage. The resulting fluid is said to acquire a specific 'potency'. In clinical use it is essential that the medicament chosen shall be appropriate to the patient's condition; fundamental to this is the contention that the various potencies can be distinguished from one another. Some years ago, I put that contention to the following test.

In consultation with an eminent homoeopathic practitioner, a former President of the Faculty of Homoeopathy, two specific potencies were selected for the test, namely, 'Natrium muriaticum 30C' and 'Sulphur 30C'. They are said to have strikingly different properties and to be strongly active. The practitioner declared himself quite confident that there could be no possibility of confusion between them.

A set of 20 uncontaminated bottles were numbered and then loaded with one or other of the medicaments, using a set of random numbers to decide which medicament should be placed in each bottle. Each bottle was enclosed in a metal can and the whole batch was sent to the practitioner without revealing the key.

No constraints were placed on the practitioner's methods, whether chemical, physical, clinical, parapsychological, or even magical, for identification of the potencies, as the question at issue was whether any distinctions could be detected regardless of means. But the practitioner kept to the routine he used in clinical practice for matching remedies to ailments. In all, he carried out 19 complete and reputedly independent tests on the same set of 20 bottles between April 1958 and May 1967, and reported his final conclusions in March 1970.

TABLE 1 Hypothetical and measured distributions from homoeopathic tests

	I	II	III
Calculated	$n = 19$	$n = 20$	$n = 380$
1. $p = 1.0$	19.0	20.0	380
2. $p = 0.9$	17.13 ± 1.3	18.0 ± 1.34	342 ± 5.85
3. $p = 0.7$	13.3 ± 2.0	14.0 ± 2.05	266 ± 8.93
4. $p = 0.6$	11.4 ± 2.13	12.0 ± 2.19	228 ± 9.54
5. $p = 0.5$	9.5 ± 2.18	10.0 ± 2.24	190 ± 9.22
Measured	10.63 ± 2.14	10.1 ± 2.55	202

TABLE 2 Results of comparisons using Student's t-test

	I	II	III
	$n = 19$	$n = 20$	$n = 380$
1. $p = 1.0$	reject	reject	reject
2. $p = 0.9$	reject	reject	reject
3. $p = 0.7$	$t = 3.9$ (reject)	reject	reject
4. $p = 0.6$	$t = 1.09$	$t = 2.49$ (reject)	$t = 2.72$ (reject)
5. $p = 0.5$	$t = 1.59$	$t = 0.13$	$t = 1.3$

The results were analysed in three ways: I, the number of correct identifications per set of 20 different bottles examined in a single run; II, the number of times each bottle was correctly identified in the 19 attempts on the bottle; III, the total number of correct identifications overall.

These scores are compared with those expected on the following hypotheses: 1, that the potencies are identifiable with certainty (that is, probability $p = 1$) as originally envisaged by the practitioner; 2, 3, and 4, that a correct identification could be expected in 90, 70, or 60 per cent of trials respectively ($p = 0.9$, 0.7 or 0.6, respectively); 5, that the observed number of correct identifications could have been arrived at by some random procedure which carries no information about the nature of the items ($p = 0.5$).

Table 1 sets out the means and standard deviations expected under each of these 5 hypotheses, for each of the 3 groupings of data, together with the actual values found. Table 2 sets out the conclusions from the various comparisons on the basis of Student's t-test at the 5% level.

The result for I ($n = 19$) cannot be distinguished either from the distribution for $p = 0.6$ or from that for $p = 0.5$ (chance). The other comparisons lead to the rejection of all the hypotheses that involve some discriminative power, leaving only hypothesis 5, indicating that the results might just as well have been arrived at by chance alone.

For a truly blind trial, each bottle should have contained material with a variety of possible activities or no activity at all. The practitioner may have been influenced by the expectation that each bottle should show activity of one or other type, in equal numbers and with no blanks, thus making the task of identification easier. Despite this bias, the statistical tests do not support the claim that the two potencies can be distinguished, at least by the methods used by this particular practitioner. It is possible that such a distinction could be derived from their clinical use, but practitioners are understandably reluctant to carry out a double-blind clinical trial that involves giving a human patient the wrong medicament. Perhaps a veterinary practitioner might be less reluctant.

Amazon flooding

SIR—In his News and Views article on Amazonia during the ice-ages, P.A. Colinvaux referred to my hypothesis that the Amazon Basin was flooded to the 250–300-m contour by a great freshwater lake during the last glacial from about 45,000 BP (but not during previous glacials as might have been understood from the text). This lake, of course, was held in by a dam across the Amazon River, not by dams across its tributaries, which were also flooded, as Colinvaux stated. As well as draining north through the Orinoco, the lake would have drained south through the llanos of Bolivia to eventually reach into the South Atlantic.

HiLoad™ - the best gels in the best columns.

New HiLoad prepacked columns from Pharmacia LKB are the first choice for preparative purifications in Standard Chromatography.

Quality packed by experts under stringent, optimized conditions, they are characterized by their convenience, reproducibility and simplicity.

Furthermore, we are introducing five outstanding new gels available in HiLoad columns, each giving superb resolution at high flow rates;

- Superdex™ 75 prep grade
- Superdex 200 prep grade for gel filtration
- Q Sepharose® High Performance
- S Sepharose High Performance for ion exchange chromatography
- Phenyl Sepharose High Performance for hydrophobic interaction chromatography.

The broad range of 20 prepacked glass columns offer you fast and reliable results in gel filtration, ion exchange and hydrophobic interaction chromatography. All bring convenience into your laboratory - no measuring, no packing, no waiting. Every HiLoad column gives you high capacity, outstanding results and reproducible performance straight from the box; just equilibrate, add your sample - and you are on your way.

Send for the HiLoad column brochure today to make your first choice!

We help you manage biomolecules.

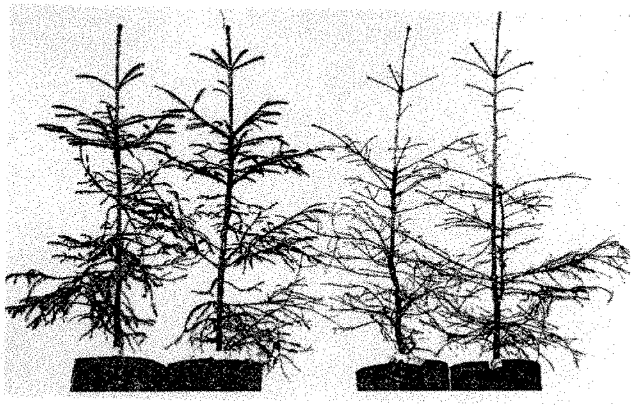
Springer books on Air Pollution and Forest Decline



D. Binkley, C. T. Driscoll, H. L. Allen, P. Schoeneberger, D. McAvoy

Acidic Deposition and Forest Soils

Context and Case Studies of the Southeastern United States

1989. VIII, 149 pp. 34 figs. (Ecological Studies, Volume 72). Hardcover DM 98,– ISBN 3-540-96889-X

Contents: Introduction. – The nature of soil acidity and H^+ budgets. – Magnitudes and patterns of nitrogen and sulfur deposition in the South. – Forest soils of the South. – Previous evaluations of sensitivity of southern soils. – Nutrient cycles and nutrient limitations in the South. – Simulation of the potential impacts of acidic deposition on forest soils in the South. – Synthesis and recommendations. – References. – Index.

E.-D. Schulze, University of Bayreuth; **O. L. Lange,** University of Würzburg, FRG; **R. Oren,** Duke University Durham, NC (Eds.)

Forest Decline and Air Pollution

A Study of Spruce (Picea abies) on Acidy Soils

1989. Approx. 495 pp. 186 figs. (Ecological Studies, Volume 77). Hardcover DM 298,– ISBN 3-540-50793-0

During the last decade, forest decline has become increasingly apparent. The decline in forest health was often reported to be associated with air pollution. The present study on Norway spruce stands in the Fichtelgebirge analyses various processes interacting within forest ecosystems. It covers transport and deposition of air pollutants, the direct effects of pollutants on above-ground plant parts, the responses of soil to acid rain, and the changing nutrient availability, and the accompanying effects on plant metabolism and growth. The role of fungi, microorganisms and soil animals in the decline of these stands is also assessed.

The volume is concluded with a synthesis evaluation of the influence of different factors, and their interactions on forest decline.

F. Scholz, Großhansdorf; **H.-R. Gregorius,** University of Göttingen, FRG; **D. Rudin,** Umeå, Sweden (Eds.)

Genetic Effects of Air Pollutants in Forest Tree Populations

Proceedings of the Joint Meeting of the IUFRO Working Parties
Genetic Aspects of Air Pollution
Population and Ecological Genetics
Biochemical Genetics
held in Großhansdorf, August 3–7, 1987

1989. VIII, 201 pp. 34 figs. Hardcover DM 75,–
ISBN 3-540-50858-9

Air pollutants provide environmental conditions that drastically differ in many respects from those to which forest trees are naturally adapted. Leading experts in the field here consider these questions of immediate relevance arising from the changing environment:

(1) Do air pollutants introduce effects of selection that diffe from those known for populations that are not subject to suc stress conditions?

(2) If air pollutants introduce quantitatively or even qualitatively novel selective effects, which consequences might arise from the adaptation of forest tree populations to the present conditions as well as for the preservation of adaptability to future conditions?

In addition to these questions, concepts for preservation of genetic resources are discussed.

In preparation

W. H. Smith, Yale University, New Haven, CT

Air Pollution and Forests

Interaction between Air Contaminants and Forest Ecosystems

2nd ed. 1989. Approx. 515 pp. 120 figs. (Springer Series on Environmental Management). Hardcover DM 198,–
ISBN 3-540-97084-3

This book is a comprehensive synthesis and overview of the complex interactions between atmospheric contaminants and forest ecosystems under low, intermediate, and high dose conditions. The author reviews the ability of forests to function as both a source of and a sink for air contaminants, and analyzes all interactions from an individual tree as well as a total ecosystem perspective. The general arrangement of the first edition has been retained, but the text has been expanded and thoroughly updated in recognition of the rapid progress of research in this field.

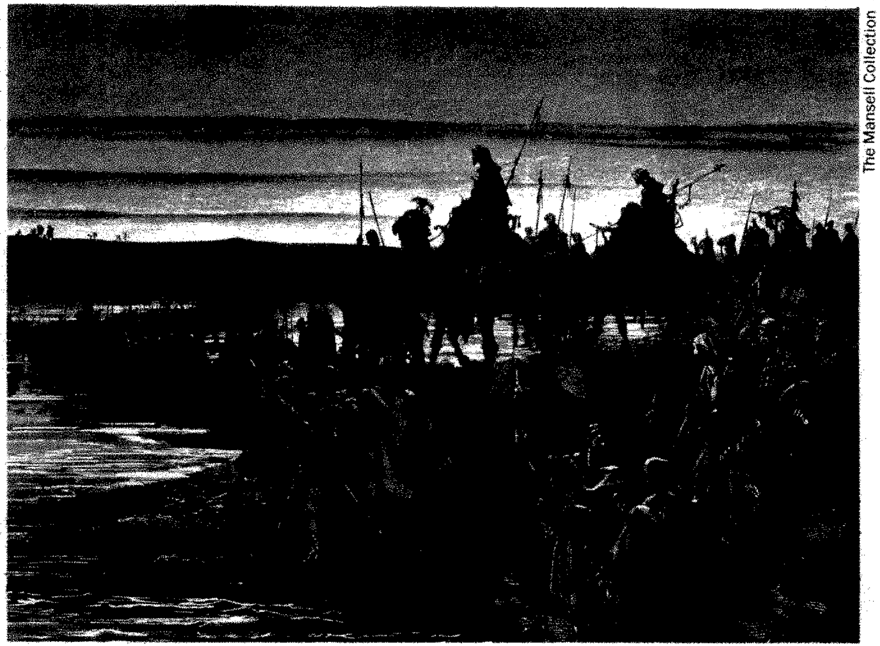
A turn in the weather

Peter J. Parr

Out of the Desert? Archaeology and the Exodus/Conquest Narratives. By William H. Stiebing, Jr. *Prometheus: 1989. Pp. 265. $21.95, £16.50.*

OLD Testament history used to be relatively simple. The Bible was, after all, generally recognized as the most complete and detailed — as well as the most readable — historical source to have come down to us from the pre-classical world, and one did not have to be a fundamentalist to believe, more or less, what it said.

But then, as a result of the literary criticism of the early part of this century, it became clear that the historical books of the Old Testament were far from being a unified narrative; rather, they were a mosaic of documents that had been written at various times, often centuries after the events they purported to describe, and had been edited with varying degrees of scholarship by a number of different people on a number of different occasions. The burgeoning archaeological discoveries in Palestine during the middle decades of the century did little to improve matters. After some initial optimism that the spade was beginning to uncover undoubted traces of the events of biblical history, it emerged that archaeology was as unsatisfactory and tantalizing a guide as the written word. The result is that for almost every aspect of the history of ancient Israel, there is now a wide range of often totally contradictory hypotheses available. All of them are capable of explaining at least some of the supposed facts; but none is convincing enough to command universal, or even majority, respect.



On the go — the children of Israel crossing the River Jordan.

The Mansell Collection

Of nothing is this more true than of the events that lie at the heart of Israel's history, and are the foundation of its religion and its national identity: its occupation of the land of Canaan and its dispossession of the previous inhabitants (the Exodus and Conquest). A vast literature has grown around the problems of chronology and causation surrounding these events. Most scholars have their own individual theories, but, as Professor Stiebing shows in the excellent volume under review, there are four or five basic hypotheses.

The first, and longest established, is the most conservative (with the exception of the real fundamentalist approach), and accepts the fact of an Israelite exodus from Egypt followed by an essentially forceful subjugation of Canaan, though not necessarily in all the particulars given in the biblical account. The second is of almost equally long ancestry. It also bases itself fairly closely on the biblical text, but sees the settlement of the Israelites more as the result of peaceful infiltration into the less densely inhabited areas of Canaan by semi-nomadic pastoralist groups from the desert fringes. A third model, proposed in the early 1960s, has proved popular with historians adopting the fashionable socioeconomic stance. It postulates an entirely internal development within Canaan, a sort of 'peasants revolt' against oppression by the ruling classes and the flight of disaffected groups away from the urban centres and towards more remote parts of the land, where their relative isolation and sense of common grievance and purpose fostered their eventual growth into a nation.

Finally, there are what Stiebing calls composite or hybrid theories which have developed from the other models. One of these sees the original Israelites not as social and political revolutionaries, but as refugees escaping from the onslaught of more warlike neighbours, such as the Philistines; another accepts the semi-nomadic pastoralist origin of the Israelites, but argues that they were not newcomers from outside the country but had been in Canaan for generations, living in symbiosis with the town-dwellers and becoming sedentary only when the Canaanite urban centres on which they depended collapsed. Just when any of these processes or events took place is also a matter of controversy; current suggestions range between the twenty-third century BC to the eleventh, though most serious scholars accept the thirteenth as the most likely, whichever theory is adopted.

By far the greater part of this book is devoted to a discussion of the arguments for the various theories and dates, each of which has its strengths and weaknesses. The task has been done many times before, but rarely as lucidly, succinctly and judiciously as by Professor Stiebing. After an admirably straightforward account of the principles of biblical literary criticism and a review of the relevant Palestinian archaeological material, the evidence for and against each hypothesis and each suggested chronology is presented fully and fairly, and is critically assessed. None of the theories is found to be wholly satisfactory, and it is this somewhat negative and disappointing state of affairs that leads Professor Stiebing to an eminently sensible conclusion, namely that "one problem with all of the models we have considered is that they view the Israelite conquest or settlement in relative isolation". As he points out, the final centuries of the second millennium in the eastern Mediterranean and western Asia saw some of the most dramatic and turbulent events of ancient history: the collapse of the Hittite, Egyptian and Mycenaean empires, and the appearance of the Dorian Greeks, the Sea Peoples and the Aramaeans, as well as of the Israelites.

Were all these events connected; did they have a common cause? Stiebing thinks they were, and argues that it was widespread drought resulting from climatic change which led to the economic, social and political disturbances throughout the region. The argument is not new, and the entire subject of the influence of climatic change on the course of human history is one which has for long engendered heated debate between determinist and anti-determinist schools of historical interpretation. The evidence from the climatological and geological sources which Stiebing reviews — though certainly less fully and critically then he does that from archaeology and the texts — is not as conclusive as he implies, if only because there is still far too little of it. But the argument remains attractive and intellectually satisfying, even if intuitive, and helps establish an 'ultimate cause' of the Exodus and Conquest.

The final question, however — which Stiebing does not address — is whether such an 'ultimate cause' really matters. A distinguished historian, Geoffrey Elton, once said that his colleagues tended to spend too much of their time on causes and not enough on results. Climatic change is a phenomenon of concern to the scientist, but what should interest the historian, and what he should seek to explain, are the different reactions of different people to the same challenge. The disturbances at the end of the second millennium may well have their origin in the same climatic events, but the consequences in various parts of the Mediterranean, Western Asia and Egypt were very different. In Canaan they resulted in the creation of the Israelite nation; and the fact that the Israelites believed their nation to have been created by Exodus and Conquest is of much greater interest and importance than whether it was really true. ☐

More heat for the debate

R. S. Pease

Nuclear Fusion. By Keishiro Niu. *Cambridge University Press: 1989. Pp.240. £35, $59.50.*

JAPAN'S research into controlled nuclear fusion became established as a substantial national programme in the 1970s, and involves a remarkable partnership between the universities, the Japanese Atomic Energy Research Institute and engineering industries. About a dozen universities have research programmes; there is a central institute devoted to plasma physics and magnetic confinement at Nagoya, and a leading institute for lasers and inertial confinement at Osaka.

Professor Niu is head of the theory group of the department of energy studies at the Tokyo Institute of Technology, and has contributed to research in fusion reactor studies. His book, which is a graduate-level text for engineering science, was originally published in Japanese in 1979 with M. Suguira of the Electrotechnology Laboratory, Tsukuba, as co-author. Now it has been translated and partially updated by Professor Niu, who presents the principles of controlled thermonuclear fusion in high-temperature plasmas confined by magnetic fields and by inertia.

The merit of the book is the wide range of topics covered. The introductory chapter leads to the Lawson criterion for the degree of confinement required for a net energy output from thermonuclear reactions, given in a form suitable for quasi-continuous systems. A chapter on magnetic confinement covers the basic properties of charged-particle motion in magnetic fields, the concept of magnetic pressure and the various heating methods. Most space is given to the Tokamak — currently the leading magnetic confinement system — and to instabilities which restrict the configurations that can be used, and those which may restrict the thermal insulation. Other magnetic systems are dealt with briefly.

The chapter on inertial confinement describes the basis of the compression and heating of small spheres of deuterium-tritium fuel by focusing onto them powerful beams of pulsed laser radiation and of charged particles. Here the author elaborates on the problems of the absorption of the radiation, describes the lasers and the methods of generating and focusing particle beams. The final chapter, on reactor design, describes some of the engineering issues, touches on resources of materials and safety, and describes three of the reactor concepts that have been developed: for the Tokamak, for mirror confinement systems and for inertial confinement, respectively.

The book deals hardly at all with experimental results, and it is disappointing to have no account of the impressive Japanese achievements in that area. Professor Niu has given himself insufficient space to expound some of the topics adequately — reading the book, one feels rather like a member of a touring party led by a ruthless guide, determined to show us everything, however imperfect our appreciation. He has also been poorly served by the proof-readers. The equation of motion describing the balance of electromagnetic forces with plasma pressure gradients is corrupted by misprints, for example; the reverse-field pinch configuration is said to arise from a diamagnetic effect, whereas it is paramagnetic; and *aficianados* of mistranslation will appreciate the "Miller" field for magnetic confinement described in Chapter 2, but translated correctly as the "mirror" only in the last chapter. Taken altogether, the book is a useful but not wholly accurate guide to the principles of hot fusion. ☐

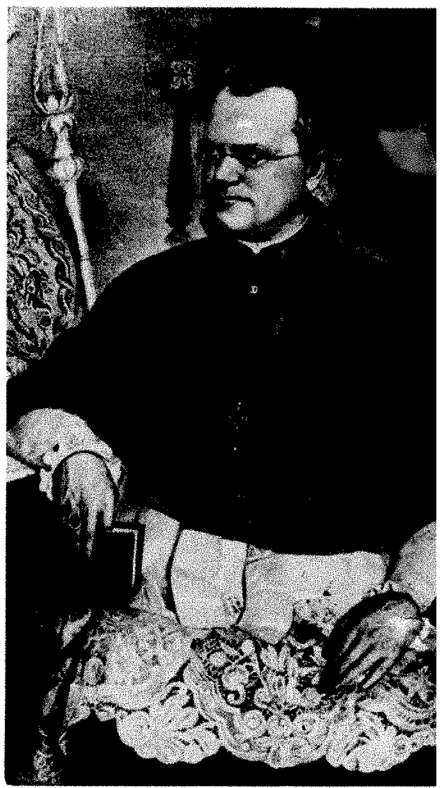
R. S. Pease was formerly Director of Fusion Research at the UK Atomic Energy Authority.

Peas before swine

J. S. Jones

The Mendelian Revolution: The Emergence of Hereditarian Concepts in Modern Science and Society. By Peter J. Bowler. *Athlone, London: 1989. Pp. 207. £35, $29.95.*

THE sociology of science bears the same relation to research as pornography does to sex: it is cheaper, easier and — as it is constrained only by the imagination — can be a lot more fun. This book discusses the changes in our thinking about heredity and evolution over the past 200 years. Those of us who teach genetics like to present the subject as unfolding logically from Mendel, through Morgan, to Crick and the latest heart-throb of molecular biology. We all accept that there may be some self-delusion here, but it makes us feel good about the rigour of our own field, and it keeps at least a few of the students awake.



Mendel's work was thought 'irrelevant'.

Bowler sees this as a conspiracy by geneticists to hide the subject's past. In this slim volume (and at a price which will make its purchasers expect something Rather Special) he argues that scientific progress makes sense only in its historical context, and that this is particularly true of the study of inheritance because of its use in justifying social policy. As he says, "most historians have little interest in defending the old view that science offers completely objective knowledge". In pursuit of this thesis, Bowler produces some interesting insights into early genetics. Few of us now realize just how unimportant the mechanism of inheritance appeared to nineteenth-century biologists. They were much more interested in cells, in development and in the nature of species, and what we now call genetics was seen as a minor part of each of these fields. Mendel's work was not ignored because it was not understood; rather it was thought to be irrelevant. Modern genetics could not begin until the study of the transmission of biological information was separated from that of its translation, and this book contains a great deal that will change the views of geneticists about the beginnings of their subject.

It is less satisfactory on the evolution of genetics in the twentieth century. Many would quarrel with the claim that Morgan became interested in the chromosome theory because it gave him access to funds, and that in the 1950s to study cytoplasmic inheritance was to side with communism. And is it really true that Kammerer's work on the inheritance of acquired characters was never duplicated only because he had an unrivalled ability to breed midwife toads in captivity? Bowler ends by pointing out the irony that molecular biology has now turned the study of inheritance full circle by casting doubt on the concept of the gene as a unit.

The book sees genetics primarily as the raw material of history and philosophy. It is a study of science and society and, of its kind, a good one. No doubt in a hundred years we will have similar treatments of selfish DNA as an example of Thatcherite greed, or of genetic imprinting and the women's movement; and there will arise new Poppers, Kants and Kuhns — a sort of philosophical Joy of Sects — all anxious to give biologists the instruction manual of how Science is Actually Done. On the tomb of a philosopher buried just across the path from Herbert Spencer (who makes an unexpected appearance in these pages as a social lamarckist) is the epitaph "The philosophers have only interpreted the world in various ways. The point, however, is to change it". Alter the object of the first sentence to 'science' and most geneticists will agree with Marx's interpretation of their intellectual priorities. ☐

J.S. Jones is in the Department of Genetics and Biometry, University College London, 4 Stephenson Way, London NW1 2HE, UK.

- *The Extended Phenotype*, by Richard Dawkins, has recently been reissued in paperback by Oxford University Press. The book is the sequel to *The Selfish Gene*, and was reviewed in *Nature* **296**, 506 (1982). Price £6.95.
- *Toward a New Philosophy of Biology* by Ernst Mayr is also now out in paperback. Published by Harvard University Press $14.95, £11.95. See review in *Nature* **333**, 25 (1988).

Drawing back the cloak

Ralph A. Lewin

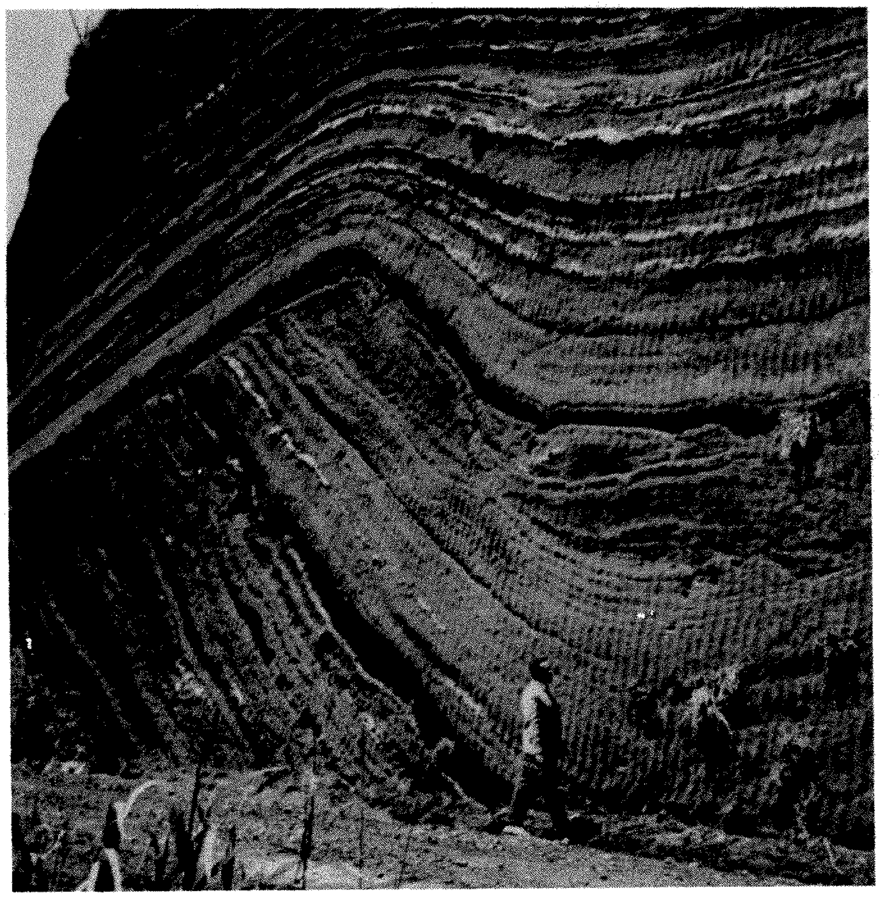
The *Chlamydomonas* Sourcebook: A Comprehensive Guide to Biology and Laboratory Use. By Elizabeth H. Harris. *Academic: 1989. Pp. 780. $145, £90.*

THE name *Chlamydomonas* — from the Greek, 'the cloaked one' — suggests something melodramatic, mysterious, perhaps even furtive. But when Ehrenberg introduced the name in 1833 he could have had no idea how much melodrama would emerge from the study of this simple-looking, single-celled green alga, or how much mystery would remain even today.

The genus is a large one, comprising many hundreds of species: a few marine, more in freshwater ponds and streams, and lots more in soils, even in deserts, from polar regions to the tropics. Put a teaspoonful of soil into a glass of water, add a pinch of fertilizer, set the glass in a window, and in a couple of weeks you'll assuredly have a culture with one or more kinds of *Chlamydomonas*, their microscopic cells swimming by means of paired anterior flagella.

To identify them further a reference work will be needed. So far, the best available has been a detailed taxonomic compilation in German, by H. Ettl (*Nova Hedwigia Beih.* **49**, 1–1122; 1976). Now there is an equally scholarly and valuable book to tell us almost everything else that we need to know about the genus — or, rather, to outline what has been discovered, how and by whom, what still needs to be studied, and how we should set about it. The scope of *The* Chlamydomonas *Sourcebook* is vast, but Libby Harris has been equal to the task. We have here a paragon of excellence.

The book presents, in clear, readable English, an overview of the huge and (almost certainly) polyphyletic genus, with chapters on cell structure, motility (those two simple-looking flagella have proven to be fantastically complicated machines), photosynthesis and other metabolic processes, and genetics of nuclear and non-nuclear genes (chiefly those of the chloroplast, now probably the best known in all biology). There are also detailed instructions for the cultivation, mutagenesis, mutant selection and conservation of strains along with some very useful



Volcanic ash layers on a road cut in Oshima Volcano, Japan. Airfall material, from volcanic eruption, forms distinct layers that follow the slope of the ground. Two generations of ash fall are seen in the picture, the beds are not folded; the inclined layers reflect the original attitude of ash accumulation. The photograph is reproduced from *Volcanoes*, by R. Decker and B. Decker, a revised and updated edition published by W. H. Freeman. Price is £11.95, $14.95.

information on the ones in current use. (As in the Bible, there is a 'begat' chapter with all sorts of details of family histories, carefully researched by Harris before memories fade and sources are forever forgotten.) Also included are descriptions of many useful biochemical techniques and methodologies for molecular biological work on such unicellular algae.

There are, too, good reviews of the sexuality of these versatile microbes, the feature which, above all else, led to their selection for detailed studies. Seventy years ago, the first direct confirmation of mendelian inheritance came from a study of *Chlamydomonas*, but for 30 years after that there were few publications on this subject (and many of those, regrettably, proved to be largely fictional). Only in the late 1940s did a handful of biologists, seeking a single-celled plantlet with genetic potential, take up studies of the genus. Mostly we chose to work with one of two unrelated species, *C. moewusii* (also known as *C. eugametos*) and *C. reinhardtii*. Their sexual proclivities are sometimes melodramatic, or even furtive, but by now they have been elucidated fairly well and are under good laboratory control. Unfortunately *C. moewusii*, which lends itself best to studies of sexuality, suffers from a metabolic disability all too common among algae, an inability to grow heterotrophically in darkness, so in this species photosynthesis cannot be bypassed. Consequently *C. reinhardtii*, with its more versatile metabolic potentials, has been the species of choice.

If I have to find a bone to pick, it would be on this point. When you read in Harris's book something about *Chlamydomonas*, you can generally assume that it relates to *C. reinhardtii* unless otherwise specified. However, generalizations are dangerous in a 'genus' as diverse as this — what's true for Peter may not be applicable to Paul — and doubtless examination of other species will reveal exceptions and surprises of all sorts.

I note that on p.175 the first equation, misquoted from Chiang *et al.*, is incorrect, and that on p.130 *C. philotes* is wrongly given as heterothallic. But I have discovered nothing of importance that's missing, and lots of fascinating details that I knew nothing about before. There are full references to almost 3,000 publications, and abundant tables, diagrams, photographs and other illustrations, with adequate scales. A good ten-page, three-column index is provided. It's all there, in a stout binding and a hard, waterproof cover. The book will inevitably need both. ☐

Ralph A. Lewin is in the Marine Biology Research Division, Scripps Institution of Oceanography, University of California San Diego, La Jolla, California 92093, USA.

Far off and exceeding deep

Harry Shipman and Noel Hart

Deep Time: The Journey of a Single Subatomic Particle from the Moment of Creation to the Death of the Universe and Beyond. By David Darling. *Bantam, London/Delacorte, New York: 1989. Pp.192. £12.95, $17.95.*

From Quarks to the Cosmos: Tools of Discovery. By Leon M. Lederman and David N. Schramm. *W.H. Freeman: 1989. Pp.242. £16.95, $32.95.*

HOW did the Universe begin? Where will it end? These questions have taken on a new, rich dimension in the 1980s with the development of a connection between cosmology and particle physics. In producing these two books, Darling and Lederman and Schramm join the crowd of scientists and journalists writing on the subject for a 'popular' audience (whatever that is).

Deep Time is a 'prose poem' telling the story of a proton which journeys from the Big Bang to the end of cosmic evolution. Some episodes in this journey illustrate a different and entertaining way of describing astronomical phenomena. Our proton hero narrowly escapes being sucked into a black hole in the centre of a galaxy, and along the way there is a nice description of the current central dogma about quasar energy sources.

But any writer takes on a real challenge in writing a book-length 'poem'. Lewis Carroll pulled it off in *Alice in Wonderland*, but Darling overdoses the reader with phrases such as "the hot breath of genesis", "oases of order" and "the mighty fortress of the second law" (of thermodynamics). One of us (H. S.) found the language merely bothersome; the other (N. H.) found it virtually unreadable.

It is hard to draw distinctions between well-founded theory and scientific speculation in a poem. Darling doesn't bother. For instance, he implies that cosmic strings must be midwives that assist in the birth of galaxies. Yet we don't even know whether cosmic strings exist. Fiction comes in, too, with tales of Prospero, the tenth planet in the Solar System. What tenth planet? Inexpert readers are here being led into the land of the tabloids, where the difference between science, pseudoscience and science fiction is considered to be irrelevant. Such readers will also have to struggle with sentences that presume a more than passing familiarity with, for instance, antileptons and antibaryons.

Lederman and Schramm provide a more conventional treatment of cosmology and its interface with particle physics. The pictures are outstanding and serve well to illustrate the sparse text, while Lederman's perspective as an experimental particle physicist shows through nicely. Many pages clearly and thoroughly, though ponderously, describe mammoth particle accelerators and the associated array of detectors. Most popular books on this topic let the stork deliver new particles, such as the omega-minuses from the clear blue sky. The authors here give us the facts of life, describing the 50,000 pictures which had to be taken before the omega-minus appeared to confirm the symmetric view of nature based on the quark model.

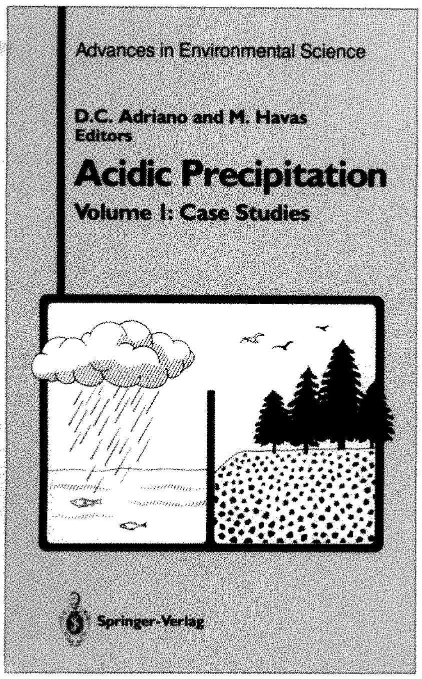
Lederman and Schramm, however, use jargon injudiciously. The book's second sentence describes the control room of Fermilab's Tevatron, but those who don't know what or where the Tevatron is must wait until page 115 for a pleasant, four-page description of it. And the beat goes on: in the first five pages the reader is sprayed with bullets of terminology: antiprotons, p-bars, accumulator storage rings, luminosity, deflection 'kicker' magnets, GeV, CDF, standard model quarks, leptons and more. One-sentence definitions of some of these bits of scientific lingo are not enough for the nonspecialist. Several pages later the level plunges precipitously. Using a box, the authors patiently explain powers of ten, and they take ten pages of text and many gorgeous illustrations to show that atoms are made of electrons and protons. Both reviewers, one of us a scientist and one a non-scientist, found the text to be like a rollercoaster ride and just as disorientating.

There is a plethora of cosmology books on the market already, including, of course, Hawking's blockbuster *A Brief History of Time*. Why write or publish so many of them? That's a question the book-buying public should be asking.

Harry Shipman is in the Department of Physics and Astronomy, and Noel Hart the Department of Foreign Languages and Literatures, University of Delaware, Newark, Delaware 19716, USA.

- An English translation of Paolo Maffei's *L'Universo nel tempo* is now available; *The Universe in Time*, published by MIT Press, addresses issues not covered in Maffei's first book, *Beyond the Moon. The Universe in Time* is structured as a voyage in time, looking at the life cycle of the stars, planetary systems and eventually geological and ecological evolution. Price $29.95, £26.95.
- Also recently translated, from the French, is Jean Heidmann's *Cosmic Odyssey*. The book was written to "give a description of the fabulous richness of the cosmos". It explores the relativistic universe, the quantum universe and the inflationary universe. *Cosmic Odyssey* is published by Cambridge University Press, price £11.95, $19.95.

Featuring an innovative 5-volume subseries on acidic precipitation



Advances in Environmental Science

Acidic Precipitation

Volume I: Case Studies

Springer-Verlag

D. C. Adriano, University of Georgia, Aiken, SC; **W. Salomons**, Haren, The Netherlands (Eds.)

Advances in Environmental Science

Advances in Environmental Science is a new series of topical reviews covering today's important environmental issues. Using an interdisciplinary approach, the series presents the research of renowned international authorities from various fields.

Beginning in summer 1989, Advances in Environmental Science will feature a special 5-volume subseries entitled **Acidic Precipitation,** which promises to be the most extensive publication on the market. The subseries will provide a comprehensive overview of the environmental chemistry and transport phenomena of air pollutants, biological and ecological effects of acidic precipitation, mitigation of acidified aquatic ecosystems, and modelling approaches. Acidic Precipitation is written for both students and researchers in all areas of environmental science, including ecology and ecotoxicology, limnology and oceanography, botany, forestry, soil science, environmental and aquatic chemistry, geochemistry, and biogeochemistry.

Integrating the most recent body of knowledge in this field of growing worldwide concern, the subseries is also an excellent resource for professionals involved in regulatory aspects of acidic precipitation.

Case Studies

1989. XIV, 311 pp. 113 figs. Hardcover DM 228,– ISBN 3-540-96929-2

Contents: *D. W. Johnson, S. E. Lindberg:* Acidic Deposition on Walker Branch Watershed. – *E. Matzner:* Acidic Precipitation: Case Study Solling. – *A. H. Johnson, T. G. Siccama, W. L. Silver, J. J. Battles:* Decline of Red Spruce in High-Elevation Forests of New York and New England. – *C. S. Cronan, R. A. Goldstein:* ALBIOS: A Comparison of Aluminium Biogeochemistry in Forested Watersheds Exposed to Acidic Deposition. – *G. Abrahamsen, H. M. Seip, A. Semb:* Long-Term Acid Precipitation Studies in Norway. – *J. T. Turk, N. E. Spahr:* Chemistry of Rocky Mountain Lakes. – *N. van Breemen, P. M. A. Boderie, H. W. G. Booltink:* Influence of Airborne Ammonium Sulfate on Soils of an Oak Woodland Ecosystem in the Netherlands: Seasonal Dynamics of Solute Fluxes. – *F. T. Last:* Acidic Deposition Case Study Scotland. – *M. Hauhs:* Lange Bramke: An Ecosystem Study of a Forested Catchment. – Index.

D. C. Adriano, University of Georgia, Aiken, SC; **A. H. Johnson,** University of Pennsylvania, Philadelphia, PA (Eds.)

Volume 2:

Biological and Ecological Effects

1989. Approx. 435 pp. 46 figs. Hardcover DM 338,– ISBN 3-540-97000-2

Reviews the current body of knowledge concerning the biological and ecological effects of acid rain on ecosystems such as streams, lakes, and forests in North America and Europe as well as soil, trees and crops in general.

S. E. Lindberg, Oak Ridge National Laboratory, TN; **A. L. Page,** University of California, Riverside, CA; **S. A. Norton,** University of Maine, Orono, ME (Eds.)

Volume 3:

Sources, Deposition, and Canopy Interactions

1990. Approx. 335 pp. 67 figs. Hardcover DM 268,– ISBN 3-540-97015-0

S. A. Norton, University of Maine, Orono, ME; **S. E. Lindberg,** Oak Ridge National Laboratory, TN; **A. L. Page,** University of California, Riverside, CA (Eds.)

Volume 4:

Soils, Aquatic Processes, and Lake Acidification

1990. Approx. 280 pp. 45 figs. Hardcover DM 238,– ISBN 3-540-97026-6

A. H. M. Bresser, Bilthoven; **W. Salomons,** Haren, The Netherlands (Eds.)

Volume 5:

International Overview and Assessment

1990. Approx. 350 pp. 110 figs. Hardcover DM 298,– ISBN 3-540-97111-4

Brazil walks the tightrope

Brazilian researchers survive with admirable calm amid an economic tempest. With strong nerves and good luck, the first democratically elected president in decades may next year bring better times.

The first round of elections to choose Brazil's president has presented the country with its first true choice since the military takeover in 1964. In last week's free and democratic vote, two candidates with diametrically opposite views were chosen to go forward to the final vote on 17 December. Both candidates are young but their backgrounds and outlooks are utterly different.

Fernando Collor de Mello (40) is wealthy, handsome and conservative. His main, perhaps only, claim to fame is the action he took to cut the salaries of 'maharajas' — enormously overpaid government officials — while governor of the small north-eastern state of Alagoas. His National Renovation Party was set up simply to promote him and has no ideological or class base. Facing him is Luíz Inácio da Silva, known simply as 'Lula', a former lathe operator and leader of the autoworkers' union. Almost exactly ten years ago he led a strike of three million workers that opened the first cracks in military rule.

His Workers Party is well-organized, well-established and supports a redistribution of income, regulation of capitalist enterprise and a moratorium on the repayment of the foreign debt.

So far there has been no sign that the military will intervene in the electoral process unless forced to do so by a major social upheaval. But if Lula is elected next month, the temptation may be strong, and there will be anxiety in Brazil. One factor staying the military's hand will be the knowledge that they have no idea how to tackle Brazil's colossal economic problems.

The best the winner can hope for when he takes over from President José Sarney in January is that the economic condition of Brazil will be no worse than today. Brazil is close to terminal hyperinflation and economic disintegration. In the five years during which Sarney has been president, nothing has been done to tackle the underlying problems.

Last year, inflation came close to 1,000 per cent. Now it is running twice as fast, at over 30 per cent a month. In daily life, the evidence of inflation is immediate and tangible. Take the 100,000 cruzeiro note; in 1986 it was worth almost ten dollars, the biggest note in common use. Three years later, the note comes as change for the smallest of purchases: it is worth less than one cent.

Money is not something solid in Brazil, it is constantly slipping away and vanishing. Fixed salaries are halving in value in less than two months; unpaid bills a few months old are not worth collecting, and items ordered a few months ago will double or triple in price before they arrive. Brazilians never know how much anything costs — only what it used to cost. Restaurants do not print prices on their menus but just leave spaces to be filled in anew each day. Taxi drivers have their meters set at some historical rate and then consult an official table – which always appears freshly issued — to convert the reading to today's charges.

Inflation has left a bewildering trail of banknotes. The 'cruzado' was created in 1986 in the Cruzado plan, the first of the government's two big attempts to halt inflation. It is worth 1,000 of the old cruzeiros. The next attack on inflation, the Summer plan, created the 'new cruzado' worth 1,000 of the old cruzado. Notes of all three currencies are in circulation, meaning that the face value of some has to be divided by a thousand and others by a million.

Dealing with inflation obsesses everyone. Salaries are constantly being revised and re-revised to try to keep up, Congress is always tied up with supplementary budgets to restore some value to budgets granted earlier. Anyone with any significant sum of money rushes it — immediately — into high-interest accounts. It is possible to make almost two per cent a day, 55 per cent a month. Industry can deal in special inflation-indexed Treasury bonds and keep itself afloat. But for those on fixed incomes, and for the poor, it is a different matter.

With thanks

One person and one person alone made possible the four-week trip to Brazil upon which this survey is based. Ricardo Bonalume Neto, a science journalist at the newspaper *Folha de São Paulo* and occasional contributor to the news pages of *Nature*, kindly volunteered to set up appointments for me within Brazil, a task which is made triply difficult by frequent breakdowns in Brazil's long-distance telephone system. Despite the problems, Ricardo always succeeded in reaching the unreachable and making appointments with the totally unavailable — and always with just moments to spare. In São Paulo, special thanks go to Ricardo for driving me around town in his vintage Beetle, despite a series of punctures.

Alun Anderson

Brazil contains vast inequalities. In the wealthy area behind Copacabana beach, every apartment building has its guard. Late at night they are the only people on the streets. Not far away one million people live in *favelas*, shanty towns — they too are visible from the beach. In São Paulo, shacks of wood and cardboard are crammed under elevated motorway intersections and line the abandoned land along the city's polluted rivers. Altogether 25 million Brazilians live in slums out of a population of 130 million.

The statistics of inequality are staggering. The top five per cent of the population control almost 50 per cent of the nation's wealth, the next 25 per cent take 30 per cent; the remaining 70 per cent of the population share 20 per cent. More than 20 million people do not have an adequate diet, five million children have never attended school, 20 per cent of all adults are completely illiterate and fewer than half can read a newspaper.

But then comes the great contradiction. Despite its third-world distribution of wealth, Brazil does not have a third-world economy. Brazil is the world's eighth largest economic power, with a GNP of $250,000 million and a $20,000 million trade surplus — the world's largest after Japan and West Germany — on exports of $33,000 million. And those exports are not the agricultural products and raw materials of a third-world nation; 70 per cent of them are manufactured products including aeroplanes, automobiles, industrial machinery, tanks, and even missiles.

Thanks to the power of the economy, the top quarter of the population — 30 million or so people — are middle class with much the same tastes in clothes, food and culture as their European or American counterparts. In the book shops in São Paulo, the bestsellers are the same as in New York — Umberto Eco, Milan Kundera and even Stephen Hawking's *Uma breve historia do tempo*. Look one way and Brazil is part of the developed world — look the other way and it is part of the third world. Brazil is in transition. What of the future? Is Brazil about to make the leap to developed-nation status or fall back to third-world status? ►

If Brazil is to emerge from its difficulties it will have to tackle its huge deficit. It is doubly hampered; it owes a huge amount of money — over $100,000 million — to foreign bankers and it has a colossal internal debt. The oil money borrowed during the 1970s was poured into vast state-owned enterprises: oil, steel, chemicals, electricity, railways and telecommunications. State capitalism may have kick-started Brazil's development but it never proved much good at providing profits. Today, the state enterprises are a huge drain on government resources. They have never been left to follow market realities but are used for a variety of political purposes. When convenient, electricity prices are set to manipulate the rate of inflation or jobs are given out to relieve unemployment in a sensitive area.

The need to finance the debt of the state enterprises is one of the factors that triggered inflation. As foreign loans vanished, the government turned to the internal market or printed money. And as the government is the guarantor of huge quantities of money in index-linked savings and bonds, it had to borrow to pay for inflation, driving the inflation rate yet higher.

The state enterprises are a social as well as an economic phenomenon. They created a new breed of Brazilian — the technocrats. Well-paid and enormously powerful, they will prove reluctant to work anywhere else. So will the army of workers they control. For all but the richest, Brazilian life is permeated with a fear of falling — falling into the abject poverty below. In a state sector job security is total — and wages are higher. Every year more jobs are created and labyrinthine bureaucracy grows.

It will be a brave politician who tackles the state enterprises. Sarney made one brief sally in January when he announced plans to dismiss 60,000 state employees (one result would have been that almost half the staff at the research facilities described below would have been out of a job). But he backed down in the face of public opposition, saying the matter was the responsibilty of Congress.

What will Collor or Lula do? Collor has so far been careful to cultivate his image while not committing himself to any definite policy, although he has said he is in favour of the sale of state enterprises. Lula's views are clearer. Corruption and nepotism are to go from the state enterprises but the enterprises themselves will remain and perhaps even be strengthened.

Without tackling the deficit it is difficult to see how the Brazilian economy can recover. But there are other things that can be done to help, Bolivia providing one example. In 1985, Bolivia's inflation rate reached 23,000 per cent but now it is under 10 per cent. Hyperinflation was ended by getting rid of the deficit, in part by the unorthodox method of reducing tax rates to the level where people — particularly those operating in the black economy — would pay them rather than cheat. Tax revenues rose several thousand times as a result. In Brazil, some economists believe that 50 per cent of the economy may be black. If that is the case, then changing the tax structure to bring them into the legitimate economy, and removing excess regulation that makes it hard for them to expand, could provide the boost Brazil needs.

Despite the sense of impending economic catastrophe, the visitor is surprised to find that Brazilians themselves are rarely downcast. Amid all the difficulties, it would be hard to find a Brazilian who does not believe the nation is destined for greatness. They may joke that "Brazil is the country of the next century — and always will be", but underneath there is unfailing optimism. They know that the ecomony can be dynamic, they know that the country is vast and vastly rich with minerals, oil and gas. When pressed, that confidence slips into the kind of xenophobia which inspires politicians and military men to threaten to cancel the foreign debt and to tell the rest of the world to go to hell.

It is in this spirit that Brazil's politicians talk about the Amazon — its their great frontier, the American West, that will be conquered and bring untold riches. The development of the Amazon is inevitable; the only questions are when and how.

But international pressure has put the environment on the political and election agenda. Some tax subsidies for 'development' of the Amazon that have encouraged giant cattle ranches have already gone, and if the pressure is kept up, others may go too. But politicians know that the main force driving poor settlers to Rondonia is poverty; expansion in the industrial heartlands would be the best hope for the Amazon, buying time until better development strategies have been worked out. But to say that is simply to return to the problem of inflation.

In the pages that follow, it will be readily apparent that scientists have no escape from the economic, political and social realities that surround them. Scientists worry about inflation, financial instability (which sends some institutes close to bankruptcy), sudden reversals in policy and the wave of democracy which is altering old power structures within research institutes. It is a time of transition. Among the cast of characters that appear in the remainder of this survey are the giants of the older generation, people who weathered the period of military rule or who had to flee into exile, a new breed of research administrators who know the routes through the labyrinths of Brasilia, frustrated young researchers fresh from foreign research laboratories, and those who have put aside personal goals to train the next generation of researchers and work for development. And of course there are some bureaucrats and technocrats too.

People will be found to disagree on many things, as may be expected. The reader must also be warned that not everything told to *Nature* is necessarily true. In Brazil, charm is a national art, and even scientists may sometimes be unwilling to let facts interfere with a well-told tale. Charm is necessary. Amid Brazil's inequalities it makes life bearable, even enjoyable. At one end of the spectrum, charm blends into the kind of good-natured, smiling persistence that is often necessary to get anything done in Brazil. Further along it turns into the skill of creating imaginative compromises and ways around rules (the '*jeito*' of which Brazilians are so proud). Yet further along it turns into corruption plain and simple.

In the opinion of this reporter, one category of researchers is special. Those who live and work in the Amazon are set apart by the extraordinary paucity of their resources and by the unique interest of their research into one of the world's least understood ecosystems. Brazil could buy some very inexpensive international prestige by deciding to make research in the Amazon a high priority — after all, the Amazon (or the greater part of it) is Brazil's alone. That research could include not only the full range of biological and physical sciences but also linguistics. With 170 separate Indian languages in Brazil, there is a unique opportunity to take the world lead in the field. This has been partially recognized in a special government project on Indian languages, but the level of activity is still far too low.

There are several other simple things the government could do to help researchers. One would be to remove completely the bureaucratic obstacles that slow the import of scientific equipment and reagents. Government officials say that rules must be applied, but that is not what is in dispute — it is appropriate rules that are needed, not those that regard all imported items as the same.

Other problems are not so easy to deal with because they are financial (the level of funding, the freeze on new appointments in the universities) or political (the unwillingness of the government to allow excellence to be rewarded and incompetence punished among the university's tenured staff).

Clearly the research milieu is now changing and there will be increasing emphasis on interaction with industry, and with boosting the dismally low level of research and development within industry. A few researchers are already seeing the future and making their own plans for new links, others might be wise to imitate them. □

ORGANIZATION

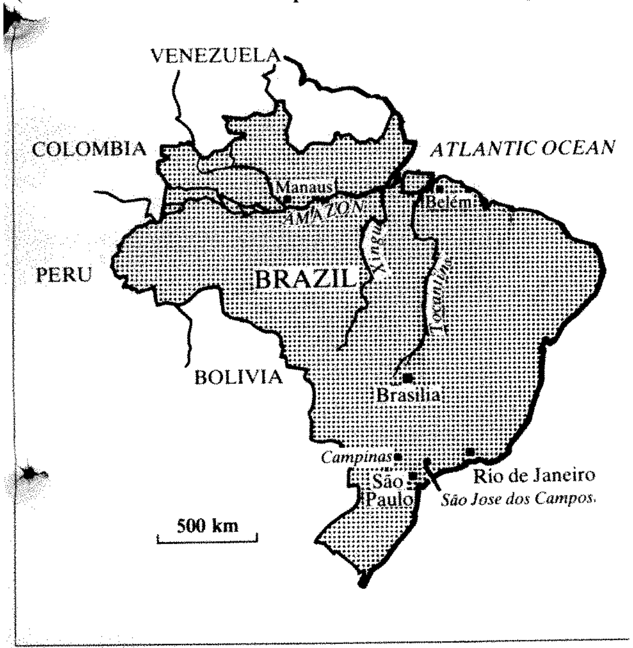
Whistle-stop guided tour

THIS page provides a map, both geographic and institutional, of science in Brazil. As with any map, its principal appeal is to people who dislike travelling without always knowing exactly where they are. Those who are content simply to arrive may turn to the following pages.

Universities. Brazil has more than a million students enrolled at its federal, state and private universities, but there are only eight universities carrying out active research in a wide range of scientific disciplines.

In a category of its own, well ahead of any competitor, is the University of São Paulo (page 368). It produces more than half the doctorates in Brazil. Second comes the University of Campinas (UNICAMP), located 100 kilometres north of São Paulo (page 368). USP and UNICAMP are not supported by the federal government but by São Paulo state which is Brazil's richest, generating 50 per cent of total gross national product (GNP).

Third is the best of the federal universities, the Federal University of Rio de Janeiro (page 358). After Rio, the rankings are open to dispute (and, of course, any university may have particular specialities in which it excels). But most agree that in the next five places will be the Pontifical Catholic University of Rio de Janeiro (remarkable as the only private university with strength in science, page 359), the State University of São Paulo (yet another of São Paulo's state-funded universities, with campuses throughout the state), the Federal University of San Carlos (again located in São Paulo state), the Federal University of Rio Grande do Sul (located in Porte Allegre in Brazil's southernmost state), the University of Brasília, and the Federal University of Minas Gerais (located in the state capital of Belo Horizonte).



Research institutes. At one time or another, all of the major research institutes belonged to what everyone still knows as the National Research Council and refers to as "CNPq". (The council's change of name to the National Council for Scientific and Technological Development has proved unpopular, page 373). Eleven research institutes still belong to CNPq; for historical reasons they are concentrated in Rio de Janeiro. Two major research institutes, for space research and amazonian research, are now attached directly to the what most people refer to as the Ministry of Science and Technology. In fact, the name is not correct. In a dramatic political battle, the ministry was absorbed by another ministry early this year but fought its way out again, victorious and independent, as the Special Secretariat for Science and Technology of the President of the Republic (page 371) a ministry except in name. The research council, CNPq, is answerable to this body.

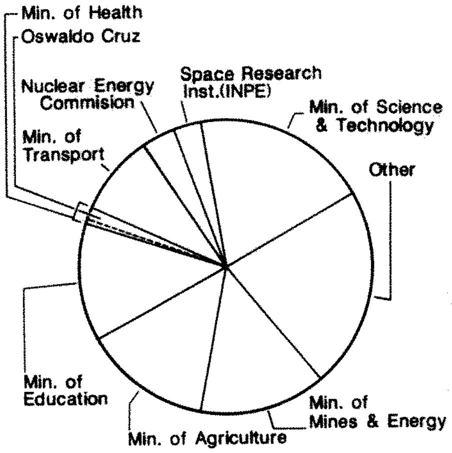
There are many other research institutes — for Meteorology, Metrology, Mining and so on — attached to other ministries but they are less central to *Nature*'s interests. Exceptions are the Oswaldo Cruz Foundation of the Ministry of Health, and the EMBRAPA chain of research institutes attached to the Ministry of Agriculture (pages 370 and 363).

Research support. Virtually all support for scientific research comes from the government. The total budget in 1987, the last year for which complete figures are available, came to $1,640 million, approximately 0.7 per cent of GNP. The following year the budget rose but in January 1989 massive cuts were ordered by the President. As supplementary budgets are still being debated by Congress it is not possible to say accurately how much will be spent this year, although the final figure could be as low as half that granted in 1987. In that year the budget was divided up among ministries as shown in the pie-chart below, with the Ministry of Science and Technology receiving $470 million (35 per cent of the total). Of that $470 million, just over half ($249 million) went to CNPq to support its scholarships, research grants and institutions (page 373). Thirty per cent went to the Agency for Financing Funds and Projects (FINEP), which is part grant agency and part commercial bank (page 372), and to two other ministry funds, the National Fund for Scientific and Technological Development (FNDCT) and the Programme of Support for Scientific and Technological Development (PADCT). The latter is particularly important because it is through this fund that the World Bank has made a $72 million matching loan to Brazil to help in the development of the science base (page 372).

Major research institutes

CNPq
Rio de Janeiro
  National Observatory (p.359)
  Museum of Astronomy and Related Sciences
  National Laboratory for Astrophysics (p.374)
  Brazilian Center for Research in Physics (p.361)
  Institute of Pure and Applied Mathematics
  National Laboratory of Scientific Computing
  Center for Mineral Technology
Belém
  Emílio Goeldi Museum (p.363)
Campinas (SP)
National Synchrotron Light Laboratory (p.368)
Brasília
  Brazilian Institute for Scientific and Technical Information
  Centre of Science and Technology Policy Studies
Special Secretariat (Ministry of Science and Technology)
São Jose dos Campos (SP)
  National Space Research Institute (p.367)
Manaus
  National Institute for Amazonian Research (p.362)
Ministry of Health
Rio de Janeiro
  Oswaldo Cruz Foundation (p.370).

Outside of the Ministry for Science and Technology, support for basic research comes from the Ministry of Education's Coordinating Agency for Advanced Training of High Level Personnel (CAPES), which supports graduate training in the universities (page 372). Individual states also have their own funding agencies, São Paulo's FAPESP is the best known and biggest (page 372). □



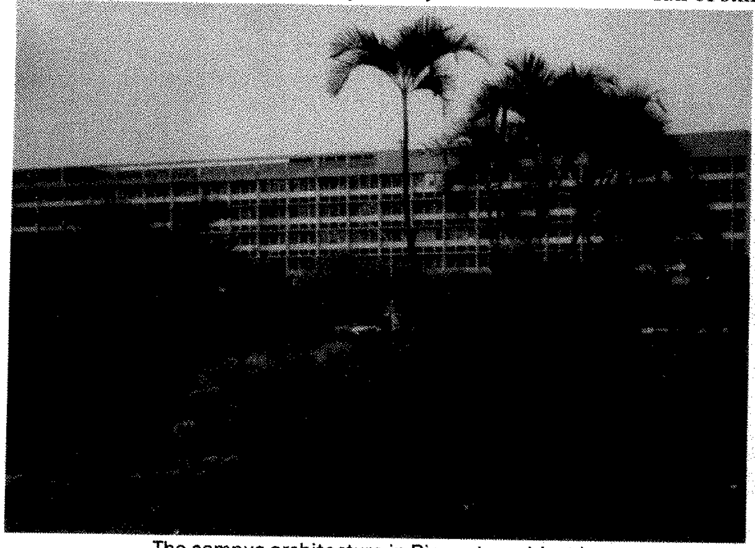
The distribution of government research spending by ministry during 1987.

Island exile for academics

Rio de Janeiro

FOR all its carnival image, Rio on a rainy day is about as exciting as Manchester, and considerably uglier. Rio is more than a few famous beaches and a soccer team; it is a city of 5.7 million people (a million of them living in slums), an industrial centre and a major port. Heading north out of Rio, the Guanabara Bay elevated expressway runs for two grimy miles alongside rows of wharves, cranes and warehouses before winding out of the city through the industrial Zona Norte. There are no tourists out there.

But Rio in the sun is another city altogether — certainly one of the most beautiful in the world — not because of anything man has built but because of its mountains and the sea. The famous Sugarloaf is remarkable only for its symmetry among an infinite variety of mountain forms — some bare rock and some covered with lush forest — spilling down to the sea and a series of beaches, bays and lagoons. There is nothing to add to the cliched speechlessness of Charles Darwin who wrote, visiting on the *Beagle* in 1832, that the landscape "so completely surpasses in magnficence all that the European has ever beheld in his own country, that he knows not how to express his feelings".



The campus architecture in Rio: not an object lesson.

Rio residents add utility to aesthetics; they like to say that the only reason that major riots do not break out in the slums — the *favelas* — is because of the open beaches and overwhelming beauty of the surroundings. While the idea of beauty as a palliative for poverty may seem romantic, in Rio it is believable.

Rio was long Brazil's capital and tries to claim the honour of being the first city to open a proper university, as against faculties or schools for the study of individual disciplines. But the motive for setting up the university was not entirely scholarly, or so the story goes. Diplomatic necessity was the driving force. The King of Belgium was about to pay a state visit to Rio, and the president found that he had no university to confer a suitable honorary degree upon his distinguished visitor. The University of Brazil was thus created, although it was not to last for long. Some of that university's buildings still remain in an old part of town, with a pleasant view across the bay to the Sugarloaf. Alongside it are two of the research institutes of the National Research Council (CNPq): the Brazilian Institute of Physics (CBPF) and the National Laboratory of Scientific Computing (LNCC). A third CNPq institute — the Institute of Pure and Applied Mathematics — also occupies a delightful site overlooking the botanical gardens on the lagoon behind Ipanema. And not far from there, also surrounded by greenery and mountains is the Catholic University, PUC.

But Rio's main university, the Federal University of Rio de Janeiro, enjoys no such picturesque setting. Almost the entire university was moved in 1972 to a low, uninhabited island, five miles from downtown Rio, just north of the docks of Guanabara Bay. Many academics claim that the the university was moved for political reasons, so that out on the island the military could be sure the students could foment no trouble.

Other academics claim the story is an exaggeration; they say the island is simply a manifestation of the "gigantism" that comes easily to the totalitarian mind. The island is artificial, created by filling in the land between eight tiny islands, and took almost twenty years of intermittent work to complete. It is two miles long and for the most part, covered in an untidy scrub. At one end stands a vast university hospital, at the other a cluster of university faculties, housed in concrete blocks, but each so far from its neighbour that it seems unlikely that there are many spontaneous meetings between the members of different faculties. Rows of students wait at the bus stops of each faculty or try to hitch a ride back to Rio. There is nowhere to live nearby.

Optimists say that it is too early to judge the project as the island will gradually fill in — new research institutes linked to private and state companies are already being built — and become an academic city. But it seems unlikely that the island will really begin to feel lived in and friendly before the end of the century. The university has 25,000 students and 3,000 faculty. Overall, it is usually described as the third-best university in Brazil, but its biophysics group is the best and its reputation in biochemistry and engineering, where the university runs a very large and innovative graduate school (COPPE), is very high.

The university faces the now classical problem of other federal universities — growth has stopped. For the past four years a federal freeze has prevented the university hiring any full-time staff (there are ways of hiring people on specific contracts). People returning from post doctoral experience abroad must thus face the dismal prospect that the universities are full of still-young people, much less qualified than themselves, who joined the university a decade or more ago. It will be the next century before the hiring bulge of the 1970s fully works itself out of the university system.

Rio has always had the pick of good graduates so the problems are not so severe here, but Professor Luiz Pinguelli Rosa, director of COPPE, explains that many universities are "dominated by people who are not concerned with research, the old-fashioned teacher, professional and bureaucratic people who just come to class and then go home, and now with political appointees who have nothing to do. But now is a time of transition". He also points out a certain irony in the present situation. Many academics opposed the military and, in the late 1960s, large numbers were dismissed or even driven into exile. But despite the military's pressure on academic freedom, they expanded the universities and put money into science and technology. Now the government has lost the will to invest for the long term.

Despite the shortages it is possible to keep good groups going. Nelson Maculan, a COPPE professor, has a team of young researchers with postdoctoral experience at universities that read like a listing of the world's best. By early October he had already received 25 visiting professors since the start of the year. But his field is theoretical — operational research — and he needs only a work station and outside contacts to stay at an international level. He despairs of how to bring back good people who have gone abroad for training when he has no jobs to offer them.

Rio is also swept up in the wave of democracy passing through the universities, another reaction to the disappearance of the military. Everywhere students, and particularly support staff who greatly outnumber faculty, are asking for a bigger say in running the universities and in electing their rectors.

Rio has gone further than most, prompting the Minister for Science and Technology, Décio Leal de Zagottis, to claim that the a "crisis" is imminent that will harm the university for a decade, slowing its attempt to form new links with industry. The courts will ultimately have to decide whether, in de Zagottis's words, a "university can be directed by students, workers and professors, all at the same level". But academics at the university say the problems are being exaggerated, and Bio-Rio, a key biotechnology venture on the island (see page 374) says its immediate prospects are good. ☐

CATHOLIC UNIVERSITY

The art of living on the edge

Rio de Janeiro

ONE of the most studied announcements on the noticeboards at the Pontifical Catholic University of Rio de Janeiro (or PUC as everyone calls it) gives the latest prediction of when staff salaries might be paid. PUC is the only private university in Brazil carrying out a substantial scientific research programme, but this remarkable achievement is rewarded irregularly in these difficult times — the salaries for January, for example, did not arrive until April. "It is a very unstable situation", says Professor Humberto Brandi, Dean of the Technical-Scientific Center (CTC) which coordinates the university's scientific programmes. "We have constant problems of money . . . I don't think you can imagine how it works. It's completely crazy."

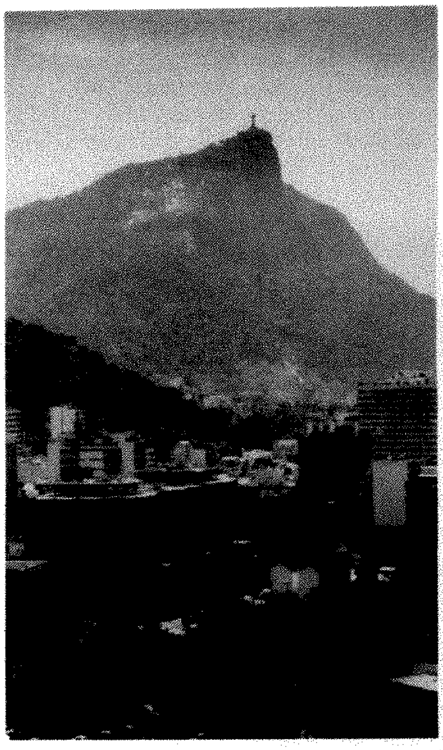
The private status of PUC makes it particularly vulnerable to economic instability as it does not have the guaranteed income of federal and state universities and must rely instead on student fees, and research grants and contracts.

PUC was set up in 1941 as Brazil's first private university. In 1959, the university bought Brazil's first computer, a gigantic US-manufactured machine that took up two floors and was part mechanical and part electronic. When the university found the computer could not be switched off, they were stimulated to appoint the first full-time staff. The university is still very strong in computer science and telecommunications; IBM is just about to donate a large mainframe computer and the telecommunications research centre (CETUC) receives large contracts from the state telecommunications organization, TELEBRAS.

The university has 8,000 undergraduate students, 3,000 of them in the Scientific-Technical Centre. The emphasis is on technology, rather than basic science. There are 1,000 graduate students in the centre, along with 260 faculty.

The faculty's funds and salaries come mostly from the research council FINEP (see page 372) and increasingly from research contracts (PUC has around 160 of them) from state and private industry. But early in October, Brandi is still waiting for September's salaries to arrive. In April, when they had been without salaries from January, he had been forced to borrow some money intended for investment in projects to pay part of the salary bill, then later repay the money, with interest. As interest rates are currently 1.8–2.0 per cent a day, this is a painful transaction. Asked why he appears so calm about it, he relies, "We have been living on the edge for ten years, we know how to do it".

This time, anyway, he says he knows the money for salaries is there, it just has to be "liberated". "Liberation" is a word that senior Brazilian researchers use often. It means a kind of guerilla-style harassment of goverment agencies until they deliver the funds that are owed. The budget is decided by the Ministry of Planning and is approved by Congress but the funds are disbursed by the Ministry of Finance. There the officials are under constant pressure from the International Monetary Fund to improve the deficit. One trick is to slow the pace of payment; because the budget is not inflation indexed, every delay means a decline in the value of the amount to be given out. Brandi and other "liberators" must thus spend their time on the telephone, and flying up to Brasília, trying to make the funds move down the pipeline.



The famous statue of Christ looks down on the Catholic University.

"Brazil is a young country and everything is very informal", says Brandi. "It's possible to pick up the telephone and talk to the minister. The ministry has its own priorities which are complicated, and works on pressure." Last month's salary has, at any rate, been liberated from the Ministry of Finance and travelled as far as FINEP. Brandi is now occupied with liberating it from there. ☐

NATIONAL OBSERVATORY

Counting pennies not stars

Rio de Janeiro

IT is the middle of October and Ramiro Muniz, vice-director of the National Observatory remarks, without any particular emotion, that the observatory is absolutely broke. "Today we do not have a single cent", he says. All that is left are some funds earmarked to pay the electricity bill.

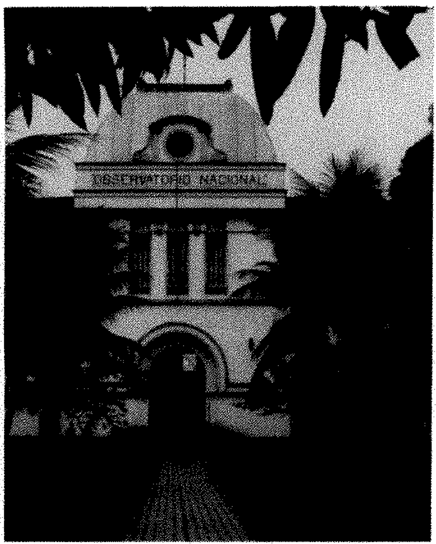
Muniz hopes that Congress will soon pass a supplementary budget, designed to resurrect funds that melted way under 30 per cent a month inflation. He explains that the observatory operating budget (which at the beginning of the year would have been worth $800,000) exists in a computerized account in Brasília. It bears no interest, nor is it corrected for inflation. It appears at the beginning of the year, and immediately begins to lose one per cent or so in value every day. The observatory tries to buy as much as it can immediately — but as Muniz says, "you cannot go hog-wild buying everything in January".

Anyway, the law prevents advance payment of government funds to private companies without special bank guarantees; it's payment on delivery, and by the time a delivery arrives, costs may have doubled, or tripled. . . .

Do-it-yourself becomes the only way to save money. The observatory has taken to mending its own cars and using its technical expertise to repair building — the workshop apparently produced a fine set of aluminium doors. Muniz clearly likes improvising. He is a physicist (and spent five years at Berkeley in the fifties) but most enjoys the times when he can use his knowledge of paramagnetic resonance in unconventional settings: verifying a colleague's hypothesis that a particular drug acts on trypanosomes through the release of free radicals, and finding that the magnetic signature left in rock cores can be used to recover temperature history. Now, necessity has made him an expert on economics and accounting. He expects no quick solutions to Brazil's problems. "The politicians are as lost as a blind man in a shoot out", he says, "they have no idea which way to run".

The observatory also has internal problems which are essentially a reflection of its origins. The observatory began in the early nineteenth century as a practical place: it made astronomical observations of use in navigation, recorded magnetic data and corrected compasses, and kept the hour, supplying a time signal at noon for ships in Rio de Janeiro harbour to set their chronometers.

The observatory (and its old telescopes) now stands on a little mango-tree covered hill in the São Cristovão region of Rio; its original hill, which was closer to the sea, was quarried away sixty years ago and used to extend Rio's waterfront. Today, the observatory is unhappily split amongst the descendants of its original functions. There are astronomers (who now see themselves as basic researchers), geophysicists (who have forged links with industry), and engineers who still keep the hour (and are looked down on by the first two groups). Muniz tries to prevent argument over the groups' respective merits, and impishly quotes Lewis Carroll on the reality behind words, " 'The question is', said Humpty-Dumpty, 'which is to be master — that's all' ". Muniz's view is that "it is less important who is in charge inside than for the observatory to be good enough to get funds from outside".



The National Observatory's roots lie in the early 1800s.

Brazil has maybe 100 working astronomers (the astronomy society has 300 members), the great majority of them either at the National Observatory or at the University of São Paulo. The main observing facility is the National Astrophysics Laboratory, associated with the National Observatory and located at Brasópolis in the mountains some 300 km from Rio. Groups from several universities use the facility, which is equipped with a 1·6 m reflector and 60 cm refractors. Brazil is not the best place for optical astronomy; there is too much cloud and not enough high mountain.

If support is forthcoming it is likely that Brazil will use a facility in the Chilean Andes, probably in collaboration with a US university group. Some observations are already made in Chile and Argentina, as well as in South Africa. Projects at the observatory include the South American part of the Harvard–Smithsonian redshift survey, a stellar astrophysics group that studies the polarized emissions from stars, and a wholly Brazilian project on T-Tauri, young stars.

Elsewhere in Brazil there is a 30-metre radiotelescope (now at INPE, at one time it belonged to the observatory) but it is already old. A consortium from the University of São Paulo and INPE and some other groups — the first time a consortium approach has been tried out in Brazil — is now attempting to find funds for a much larger radio array.

The observatory's geophysicists are responsible for Brazil's magnetic and gravimetric surveys. They also do seismic work with Petrobras, the state oil company. North-east Brazil is seismically active although no shock bigger than Richter 5 has been recorded. Much larger earthquakes are believed to have passed unrecorded in the Amazon, and there are plans to set up a seismic station at Manaus — when and if the money becomes available. □

SBPC

Science as continuous struggle

Rio de Janeiro

Ennio Candotti is a name known to virtually all Brazilian scientists, which is some measure of the continuing importance of the Brazilian Society for the Progress of Science (SBPC), of which he became president this year. SBPC is the exact equivalent of the AAAS in the United States, it organizes seminars and holds an annual meeting (which as many as 10,000 people attend), it lobbies the government on behalf of scientists, and publishes a scientific magazine.

Candotti is a busy man, constantly in demand. He is not without his critics, who fear he might not be big enough to force the government to provide science with the support it needs, or suspect he has become too much of a journalist after having spent seven years as editor of SBPC's monthly magazine, *Ciência Hoje*.

By training, Candotti is a theoretical physicist. Over a lunch, taken late in the kitchen of the Oswaldo Cruz Institute (the official lunch in the dining room had ended an hour earlier and all the guests had gone home, but a series of interruptions, and people queuing to talk to him, had so far prevented Candotti from actually eating anything), he characterized, somewhat melancholically, the state of Brazilian science as "continuous struggle".

"For each hour of investigation, there are ten hours of fight to get the money, to get equipment, to solve the problems of stability for your laboratory. Every person is divided between two jobs, one is the old job we used to have, the other is the fight to maintain the old job. . . . We dream of a stable budget, to have equipment, to have libraries, but we don't get them". The result is that Brazilian scientists have become very ingenious. "If you gave them half of what an average US scientist has, they would be able to achieve three or four times as much", Candotti says, half-seriously.

"Political interests are always present in scientific life," says Candotti. "Why? Because the whole Brazilian problem is political. Fifty million people are undereducated and without health care, 30 million are without basic instruction, 60 million earn less than $60 a month. At the same time we have a very powerful industry and economic growth. It is these contradictions that must be solved to give stability. We need 100,000 researchers, we have 30,000, we don't have people to do the most simple things. But the government does not have the stability itself to provide continuity to a programme for

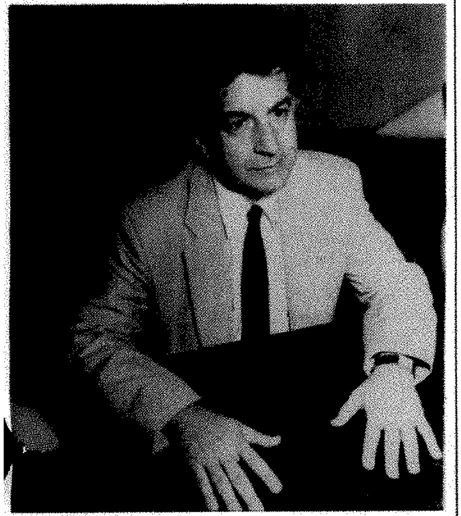
SBPC
A ARTILHARIA DOS BESOUROS

SPBC's monthly magazine, *Ciência Hoje* (Science Today), has a circulation of 70,000 and is "written by scientists, rewritten by journalists", according to SPBC director, Ennio Candotti. It is modelled on *Scientific American* and *La Recherche*.

four or five years . . . 30 per cent a month inflation destroys all plans and budgets."

Inflation is something Candotti had direct experience with as editor of *Ciência Hoje*. "I buy so many tonnes of paper, but one month to the next costs can grow by 50 per cent; and by the time you receive the magazine subscriptions they are worth nothing, so how can you do the next issue?" Candotti's job now is part lobbyist for the scientific community. SPBC is not the only lobby group; the 60 scientific societies of Brazil also have a nine-person commission to lobby Congress and the ministries, and other groups represent individual universities and research institutes. Although some argue that the appearance of these new groups means that the SBPC is not as strong as it was, a better explanation might be that society is maturing and SPBC no longer need be the only opposition group, now that military ruler has ended.



SBPC's Candotti: The table is bare.

Candotti welcomes the appearance of other groups. "In the last year or so, society is becoming more organized, although there are no true political parties, there are more pressure groups. In the recent discussion of the new constitution, many groups were organized. Perhaps this will change the next government, it will not be completely free to govern by authoritarian methods, but will have to work with society. Congress has a new and important role".

So far, he says, there has been too much arbitrary political influence over scientific programmes. "If the minister changes, then the whole scientific enterprise can change 180 degrees. Elsewhere they are more pragmatic, here things can change from one direction to the opposite . . . all programmes, all priorities can be changed in a few months."

While Brazil may be more unstable, the job of lobbying the government is little different from elsewhere. Politicians give you attention "according to your political force, who you represent and who you can mobilize", says Candotti. ☐

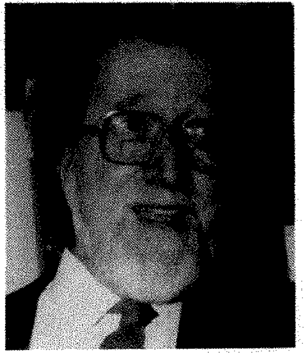
PHYSICS CENTRE

Physics in times good and bad

Rio de Janeiro

PROFESSOR José Leite Lopes' office in the Brazilian Center for Research in Physics (Centro Brasileiro de Pesquisas Físicas, CBPF), where he is director, is decorated with photographs of Wolfgang Pauli (who he knew when he was in Princeton), and Albert Einstein (taken on a chance encounter); the corridors nearby bear giant pictures of Richard Feynman and Brazilian colleagues, taken on one of his several stays at CBPF. The treasure among them is one of Feynman dressed as Mephistophiles for the 1952 Rio carnival.

Those early days were exciting — the beginning of physics in Brazil. In 1947 Cesar M. G. Lattes, then just 21 years old, had taken a set of exposed photographic plates from Chacaltaya, the cosmic ray observatory high in the Bolivian Andes, to C. F. Powell's laboratory in Bristol, England. The result was the discovery of the pions and their decay which was published by Lattes and Powell in *Nature* in 1947 and won Powell the 1950 Nobel prize. Leite Lopes, who was then in his mid-twenties, published his own work on meson decay and the theory of nuclear forces, also in *Nature*, in 1948. The next year, these two young scientists (Lattes, fresh from Berkeley, where he had won further fame and had appeared on the cover of *Life* magazine) set up the institute where Leite Lopes is now director. "The university", says Leite Lopes, "did not understand research, so we set up up our own organization, beginning as a private institute and helped by the prestige of Lattes". A few months later Feynmann came for a couple of months, he was back in 1951 for his sabbatical year, and again afterwards. There were other famous visitors too — J. Robert Oppenheimer, Eugene Wigner and Chen Ning Yang among them. But this lively period came to an end with the military coup in 1964. After being briefly detained, Leite Lopes moved to Paris, but returned to Rio in 1967. Two years later he was expelled by the military government. "I was clearly a progressive," he says. He moved first to the United States and then to the University of Strasbourg, where he remained in exile for 15 years, "working hard and living well — a gift from the generals". In 1985, with military rule ending, he was invited back, to be director of CBPF for the second time. In the meantime the institute had become one of the 11 CNPq research institutes.



Leite Lopes: returned exile.

Leite Lopes' "progressive" leanings still show; although the problems of the institute (simply put: "we have no money . . . if they take anything more we can only go to the beach") are foremost in his mind, he bunches his fists with anger when he talks about the state of Brazilian society, the ten million children living in *favelas*, and the breakdown of the public education system that had provided for poor people.

Back at the institute, Leite Lopes' main task has been to try to build the experimental physics that is largely lacking from the Brazilian scene, except at the University of São Paulo. The institute's own linear accelerators are 30 years old and no longer work. One success was the designation of the institute as the National Laboratory of Nuclear Fusion. But the plan, to study muon-catalysed fusion, exists only on paper.

Despite the lack of sophisticated equipment, several groups at CBPF look after themselves very well. Some have worked out ways to work with scientists abroad, others have adapted their science to the equipment available in Brazil. The institute has 93 researchers and more than a hundred graduate students.

The institute still has several projects going on at the Chacaltaya cosmic-ray observatory, now in cooperation with the University of Tokyo's Institute for Cosmic Ray Research. But the jewel in the crown is the group of 20 high-energy physicists, led by Joao Anjos, which works closely with Fermilab in the United States; the group even had President José Sarney pay Fermilab an offical visit in September. The group has built (at a surprisingly low cost) a parallel multiprocessor, a twin of the ACP machine at Fermilab, enabling all data gathered at Fermilab to be analysed back in Rio.

A group studying hyperfine interactions has taken the option of tailoring its science to available equipment, rather than gathering data abroad. CBPF pioneered research on the Mössbauer effect in Brazil, and has carried out the most complete Mössbauer studies of the new high-temperature superconducting materials.

Leite Lopes is thinking of returning to France to an emeritus professorship at Strasbourg and leaving the problems of Brazil to someone younger. His critics (of which he has rather few) do not mention his age, but that he is too big a figure for today's Brazil. The same comment is heard of others from his period (including University of São Paulo rector, José Goldemberg), particularly of those who spent time in exile. As one researcher put it, "only giants could still do good science through all those times". ☐

Fighting for the Amazon

Belém

ON the waterfront in Belém, flat-bottomed river boats, hammocks swinging between their open decks, bring all the curiosities of the Amazon to market. There are huge fish and unfamiliar fruits. A row of stalls sells medicines and charms — herbal oils, lizard skulls, alligators' teeth, dolphins' penises, turtle shells, and blue-and-white banded snakes, with milky, opal eyes, suspended in jars of fluid. Close by, a little shop sells the curious paraphernelia of the African-derived Umbanda religion, which includes among its pantheon St George (complete in shield and armour, slaying the dragon), Iemanjá, white-robed African goddess of the sea, and Pai Joaô, a cigar-smoking black slave.

Even the ice creams are Amazonian; alongside the familiar tropical tastes of pineapple, guava and mango are açai, bacuri, caju, cupuaçu, muruci, graviola and genipapo*. Several of these fruits are collected from the forest and not yet grown in cultivation. Even so, it is just a matter of time before they reach New York: the agricultural research station in Belém has worked out how to spin-dry and powder some of the fruits for long-term storage.

Belém is just south of the Equator, 2,000 miles north of Rio de Janeiro and 80 miles from the open sea. It is the capital of Pará, a state almost six times the size of Great Britain. Although an exotic place for the visitor, Belém is also the home of three of the most important scientific institutions within Amazônia: the Emilio Goeldi Museum, which is the region's oldest scientific institution, the Federal University of Pará, and the Centre for Agricultural Research in the Humid Tropics (Centro de Pesquisa Agropecuária do Tropico Úmido, CPATU). The heads of all three institutions have much on their minds — the parlous state of their finances, politics, their research plans and, not surprisingly, the emergence of the Amazon as a world issue. On this latter issue they all agree that rational, sustainable development of the Amazon is the only way forward (not the irrational development of some of Brazil's giant projects, nor the rational non-development of diehard conservationists), but they disagree on other points, particularly on how well Brazil has done so far and on the role foreigners might play. □

*These fruits are *Euterpe oleracea, Platonia insignis, Anacardium occidentale, Theobroma grandiflorum, Byrsonima crassifolia, Annona muricata* and *Genipa americana*. Some are found only in the Amazon region, others are cultivated throughout the tropics.

An Amazon University for Amazônia

NILSON Pinto Oliveira is rector of the Federal University of Pará, which occupies a campus down by the river on the outskirts of Belém. The university would not come on anyone's list of the best universities in Brazil, but it is the best in the Amazon — and not just the Brazilian Amazon, but the whole region.

Oliveira knows the potential of the region and the reality of his resources. The university has 1,500 faculty but just 135 with doctoral degrees — one trained researcher for every 36,000 square kilometres of the Amazon. But as Oliveira says, there is no time to stop, "the Amazon is not simply a place to admire, its a country where people live and will continue to live. The people are poor, they need money for the next day."

Oliveira has been rector for three months and clearly chafes at the many restrictions under which he has to operate. His first priority is to raise the level of training of the university staff and help improve Amazon educational standards. "We cannot talk about the protection of the Amazon region if we do not give to the Amazon people the possibility of learning and understanding their problems", he says. The university, along with other institutions in the region, is running a scheme to retrain school teachers. At sites throughout the Amazon, some 2,000 schoolteachers come to twice-yearly three-month courses. Raising university standards is exceedingly difficult. Most of the faculty, perhaps 90 per cent, do no research but simply attend the university to teach. A considerable number bend the rules and hold other jobs elsewhere. The four-year-old freeze on appointments prevents new staff being brought into the university. And central control by the Ministry of Education prevents change.

If Oliveira had his way, he would prefer 500 well-trained researchers than the 1,500 staff he has now. He sees lack of flexibility as an even bigger problem than inflation or shortage of money. "All universities are considered to be the same by the ministry", he says, "But the priorities here are completely different from the University of Rio de Janeiro. I cannot create posts in the area they are needed."

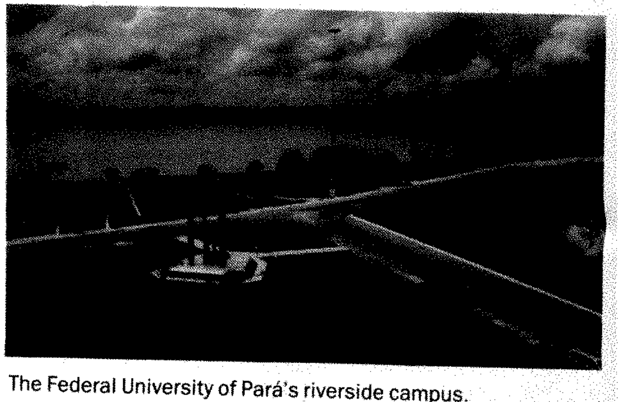
The university hopes to consolidate its resources in environmental research in a Centre for Ecological Science. Foreign help is needed to train people. But Oliveira, like others in Brazil, is convinced that foreign help must be true cooperation which will build up expertise i the Amazon.

Perhaps 70 to 80 people at the university are involved in research. Geoscience is one active area and is involved in a collobortive project funded by the US NSF to study the Amazon shelf off Marajó Island. Another active basic research group, in primate genetics and evolution, is run by the husband-and-wife team of Horacio and Maria Cruz Schneider.

Oliveira: making the best of things.

Their research has received a bonus from the construction of some of the Amazon's controversial hydroelectric dams. When the reservoirs are flooded, power companies are under obligation t catch large animals trapped by the risin waters and release them elsewhere. The Schneiders collect blood samples from captured monkeys. Study of blood groups, serum proteins and chromosome types enables questions of New World primate speciation and evolution to be tackled.

The Schneiders' efforts are quite heroic. The laboratory roof sometimes leaks, the water and electricity supply are unreliable, and 90 per cent of their electrophoretic reagents have to be imported with all the delay and bureaucratic uncertainities that involves. The university is too poor to afford journal subscriptions. Instead, the primate group has banded together to pay for airmail delivery of *Current Contents*. They then write for reprints to the authors of relevant work. The team has great spirit; all 15 primate researchers are young and are committed to refusing any side jobs. They are also building their international links; members of the group are slowly being 'strategically placed' on fellowships at universities in the United States, Japan and Europe. □



The Federal University of Pará's riverside campus.

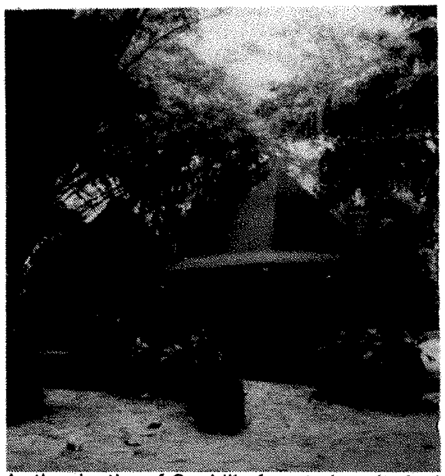
Museum ups and down

GUILHERME de La Penha is director of the Museu Paraense Emilio Goeldi, to give it its full title. The museum is old, established in 1866, and looks as though it has emerged from the pages of a Persian miniature painting. In a densely wooded, walled botanical garden are set pools and aviaries full of the birds and beasts of the Amazon: manatees, jaguars, giant river otters, cranes and toucans — 600 species in all. Almost half a million visitors come here each year. Its scientific heyday was early in the century when the Swiss zoologist Emil August Goeldi was director and began its collections of biological, ethnographic, archaeological and geological specimens.

The past few years have seen a revival at the museum, for which de La Penha can claim some credit. The museum is quite small, with around 100 scientists, and has been able to adapt to changing cirumstances more quickly than INPA, the much larger Amazon research institute in Manaus.

De La Penha says some 30 or so of the staff are now producing "good science", and have won back an international reputation for the museum. Both the Ford Foundation and the MacArthur Foundation are supporting research there and more than 40 people have been sent away for postdoctoral training. The hope is that their gradual return will take the museum to a much higher level. The museum's rising fortunes were celebrated in October with the grant of 30,000 hectares of natural forest at the junctions of the Xingu and Amazon rivers. A new field research station is to be equipped, most probably with help stemming from an environmental memorandum of understanding signed between Great Britain and Brazil earlier this year. The agreement was a nice coup for the British Embassy's diplomats, having been signed at the height of Brazil's annoyance with foreign 'interference' in its Amazonian policy.

But that is the good news. The bad news is that the museum is very hard hit by this year's cuts in funding for science. De La Penha appears under siege. "We cannot buy equipment, we cannot buy books. Everything that is important and imported has become impossible for us", he says. Inflation has also taken its toll." The value of salaries has fallen so much that most scientists are living on their savings", he says. "Now we're always worried about how we will reach the end of the month. You want some peace to publish manuscripts, but you go to bed wondering how can you survive."



In the depths of Goeldi's forested zoological garden.

Even in Belém, Brazil's political turmoil is felt. The museum is one of CNPq's institutes and CNPq has come out against the idea that all members of an institute — including the large numbers of support staff — should have an equal vote in deciding how it is run and who runs it. But depending on the presidential election, 'democracy' may triumph. De La Penha is disgusted with the intrusion of politics into science. "Incompetents are reaching high positions in the universities and institutes", he says, "although there is meant to be evaluation by peers, peers are afraid the person they evaluate may prove to belong to the right political party. If you're popular you get elected, it doesn't matter if you're competent, you must be popular with students, clerks. . .".

De La Penha is not a stranger to political fights. He left the country in 1983 after quarrels over planning for research in Amazônia. He had been vice-president of CNPq and organized a meeting in Santarem to discuss a plan for development of the Amazon. "Even today it is the only written plan for research in the Amazon", he says, "then we tried to put on pressure to create a tropical research programme, we also criticized the Interior Ministry, showing that many of its project funds just supported the infrastructure of institutes and were not used for research." These and other activities got de La Penha into hot water, and he accepted 'exile' to a job at the Organization of American States in Washington, DC. But two years ago he returned to Belém. His aim now is to establish a small, very strong scientific institute and not to interfere with the Amazon development agencies. "If it is strong it will be heard", he says,"and will provide hints, not solutions, of how to develop the Amazon on a rational basis. The Amazon is a complicated set of limited regions that need to be looked after differently, you cannot have a theory of the whole Amazon."

Foreign collaboration is bound to play a big part in the study of the Amazon, says de La Penha. He laughs at politicians who "every time you talk about foreign cooperation in the Amazon, say its a foreign trick". "We have to have added cooperation. Most of the research on the Amazon is still published by US and UK scientists. They have better continuity and can carry on a project for years. There are segments of Brazilian science who say, leave the Amazon to Brazilian scientists. But that would be one scientist for how many thousand square kilometres? Brazilian scientists must enter the international community. You cannot learn if you attend only regional conferences."

But foreigners who have jumped on the rain-forest bandwaggon are another matter. He wishes that some of the 'Save the Rain Forest' groups in the United States would spend their money in Brazil where it is urgently needed, instead of on "parties and lobbying" in Washington.

The museum is desperate for the most basic equipment. De La Penha managed to buy up one truck load of glass containers that were not good enough for the Smithsonian Institution's needs. He hopes to get another, and dreams of good microscopes and, even more, of personal computers. ☐

Short shrift for foreign do-gooders

ASKING CPATU chief Emeleocípio Botelho de Andrade about his views on foreign interest in conserving the Amazon provokes an explosion. There is "nothing but emotion, disinformation and economic interest" behind international criticism of Brazil's conduct, he says, "foreign powers are afraid that Brazil will develop as quickly as Japan or West Germany".

CPATU's job is to help speed the agricultural development of Brazil's humid tropical regions, so Botelho de Andrade's annoyance over foreign criticism is understandable. The institute is one of the 27 research stations — each responsible for a particular product or agricultural zone — belonging to EMBRAPA, the agriculture ministry's research organization.

Energy policy is a prime example of foreign perfidy, in Botelho de Andrade's view. West Germany and the United States have taken $8,000 million from Brazil for the development of nuclear power plants with almost no return on the investment, he says. But when Brazil wants to develop hydroelectric power, the cheap and logical energy source for Brazil, the same nations stir up problems over the Indian peoples who live at dam sites and try to block Brazil's development.

He claims the foreign view of the agricultural capabilities of the Amazon is too pessimistic. The Amazon's soil and vegetation types were mapped in a huge radar project (RADAM) a decade ago. Much of Rondônia, where forest burning has provoked greatest outrage, has fertile soil capable of sustaining agriculture, he says. Overall, he estimates that 8 per cent of the Amazon will prove to be highly fertile, an papers. This year, for the first time, the group will pick up substantial funding inside the country, from the Bank of Brazil. The funds will provide for a project on mercury pollution of rivers from gold-mining operations by unlicensed prospectors. A preliminary study on the River Madeira in Rondônia has already found dangerous levels of mercury in three locally eaten kinds of fish.

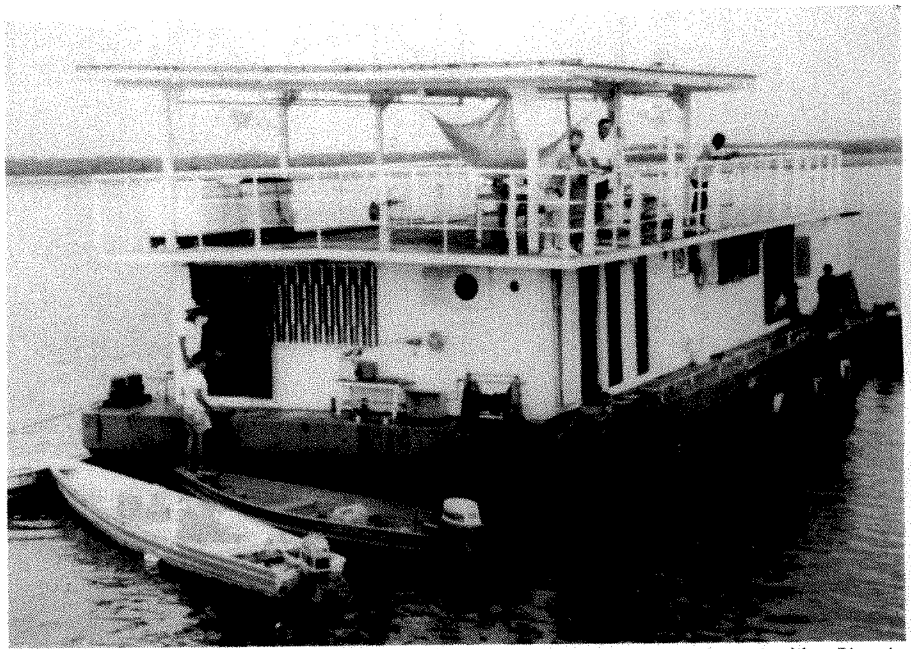
Like several other foreigners at INPA, Forsberg has been able to become an official employee. He has a tiny office, about the size of an American cupboard, in the centre of which he perches on a curious home-made stool, apparently of his own invention. Phillip Fearnside is another foreign staff member and the biggest star internationally. His work on human settlement in the Amazon and his critiques of the giant development projects — the TransAmazon highway, the Balbina dam, Ludwig's Jari colony and the Carajás smelting project — have turned him from lone academic to international spokesman. To his credit, Fearnside's studies have won tremendous respect inside Brazil; despite his criticism of many government projects, he is not regarded as a mere interfering foreigner. Fearnside, a very tall and very thin American, with a moustache that would be the envy of a walrus, is still a quiet academic. But he seems to enjoy the fact that complete strangers sometimes recognize him from his televison appearances, even in the wilds of Rondônia.

That foreigners can become employees, and that they can apply for Brazilian research grants, is evidence of open-mindedness on the part of the Brazilian scientific community. But that foreign researchers sometimes obtain both Brazilian and foreign funds can also provoke envy. And regrettably, some insensitive foreigners have come here like colonists of old, completing their projects and departing, leaving nothing behind for their hosts. INPA is considering whether it should begin charging overheads to visitors.

Brasilía too is sometimes heavy-handed. Foreign collaborations do require a complete, matching set of Brazilian and foreign partners, but application of the rules is often cumbersome and has slowed good projects.

Foreigners are luckily immune from the institute's politics, of which there is far too much. Among its most senior people are some with poor scientific credentials whose ascendancy owes much to good political connections. But that perhaps just adds another dimension to an institute whose main quality is enormous diversity in approach, quality and style. There are researchers — both Brazilian and foreign — with an international reputation and others who rarely publish, even in an obscure local journal. There are researchers such as Ilse Walker, who is as happy arguing about population biology or Eigen's hypercycle theory (or anything else) as she is on the river collecting zooplankton, her speciality. Others appear not to have read an international journal in a decade. And there is the mix of people pursuing quite practical problems, such as the suitability of Amazon timber for building, and those whose interests are in basic research, modelling energy flows in ecosystems, for example.

Such heterogeneity may be both stimulating and reveal a weakness: in a visit of only a couple of days, it is possible to uncover researchers who have never heard of one another, even though their work has considerable common ground. That surely suggests a loss of common purpose. Perhaps it is time someone began to organize some institutional seminars. □



Boat people. The well equipped floating laboratory, crewed by scientists from the Max-Planck-Institute (see below).

Almost too many species to count

Close to Manaus, the Rio Negro is several miles wide. Out in a boat the eye is drawn not to the river, nor to the green line of the forest, but to the sky, a vast sky like that over the ocean or the prairies. Over the day, a series of giant clouds form, build into fantastic storm shapes and then resolve themselves in short, torrential rain showers (see following page). Here the Amazon is flat and the views distant; the river is descending towards the sea at a mere metre every 100 km.

Upstream is the Anavilhanas, the world's largest freshwater archipelago, where the Rio Negro divides into a myriad channels. Downstream a few miles the black waters of the Rio Negro join the pale brown waters of the Rio Solimões. The two flow together for miles, mixing only slowly to form the Amazon. Freshwater dolphin live here and follow passing boats; one species is a curious shade of shocking pink.

A little distance up the Solimões, anchored in a channel away from the main river, is a floating laboratory run by an INPA-based group from the Max-Planck-Institute for Limnology at Plön. It is a meditative spot, the silence broken only by the cry of birds (some of which have a startling resemblance to the cormorants and kingfishers of Europe). Small boats pass by now and again in a larger channel, destination unknown. One researcher speculates out loud if it might be nice just to buy a boat and set off wandering up the Amazon.

There is a host of interesting problems that can be studied from here, including the hydrology and chemistry of the river itself. But many researchers have turned to the interaction between the river and the land, which is both more visible and more complex than in temperate zones.

The banks are muddy, not because there are tides, but because the river may fall as much as 15 metres between the high season in June and the low in November. Each year, a cycle is repeated in which shore-dwelling plants and animals are first inundated and then left high and dry, and river fish move in beneath the flooded forest and then out again with the retreating flood waters. The result is a unique environment in which plants and animals must adapt to both land and water phases. There are fish that live exclusively on the fruit falling from the forests, others that breathe air to get them through the flood phase when organic matter is decomposgradually run down? The researchers do not know yet, but the project is intended to continue for another 20 years. Along the way, the project should provide many data to test theories of island biogeography and come up with some practical idea on how groups of Amazon species can be maintained. □

INPE-SPACE INSTITUTE

At the centre of a storm

São Jose dos Campos

It is a curious circumstance that if it were not for a quarrel over deforestation of the Amazon, the National Institute of Space Research (INPE) would be little known abroad. International recognition, or at least the attention of the international media, came to the institute ealier this year when President José Sarney claimed that satellite data analysed at the institute showed that a mere 5.12 per cent of the Amazon had been cut down since 1500. In the quarrel over the validity of the figures that followed (see *Nature* **339**, 86; 1989), the world press descended on the institute.

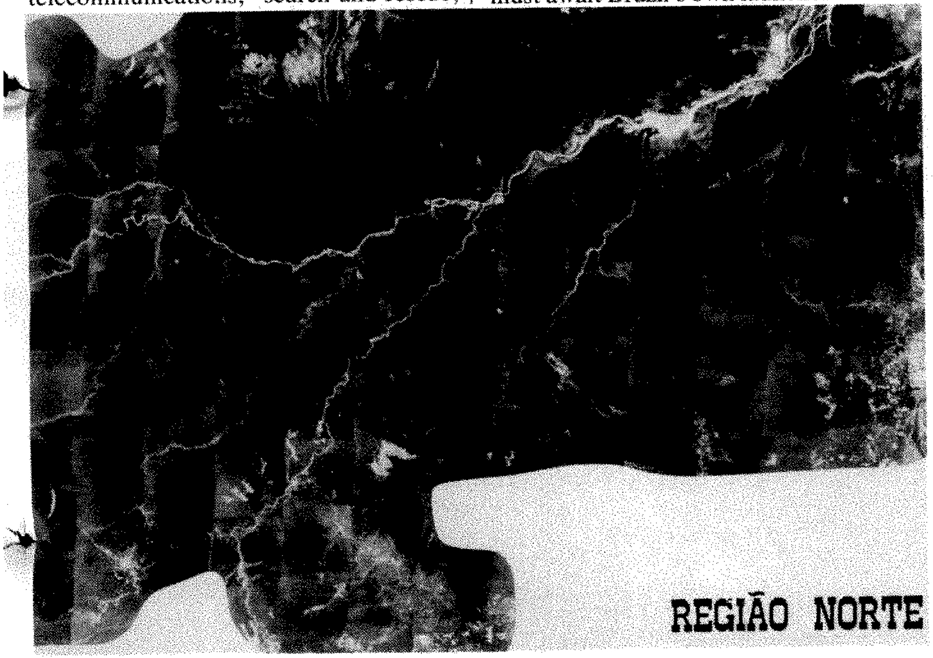
Remote sensing is in fact only one part of what INPE does. It is Brazil's biggest single research institute, employing more than 1,700 researchers in the fields of atmospheric science, astrophysics, space science and meteorology. The institute is responsible for Brazil's satellite programme and will soon see the completion of the nation's first indigenous satellite, SCD-1, being fabricated at the aeronautics company Embraer to INPE's specification.

The 115-kg SCD-1 is a relatively unsophisticated satellite, designed to collect meteorological data from 10 land stations at remote sites across the nation and retransmit them to a receiving station in Mato Grosso. But the satellite is also a key engineering test bed. By 1995, Brazil plans to launch seven satellites for use in telecommunications, search-and-rescue, meteorology and exploration for mineral resources. That, at least, is the plan.

A major difficulty is that a separate programme to develop rocket launchers being carried out by the Space Activities Institute of the Aeronautics Ministry is way behind schedule. A one-third size scaled-down version of the rocket was launched successfully last May but there is little chance that the full-scale rocket can be ready before mid-1992, more than two years after INPE could have its satellite complete.

The rocket programme has been held up partly because of the unwillingness of the industrialized powers to transfer technology to a programme that is controlled by the military and could easily be diverted for use in long-range ballistic missiles. US refusal to sell inertial guidance systems to Brazil triggered a minor diplomatic row in April. But things are unlikely to change, given that Brazil is an important arms supplier to developing nations and provided rockets, tanks and armoured cars in the recent Middle East conflict.

Many within INPE would like to see a foreign launcher used to put the first satellites into orbit and so keep their part of the programme on schedule. A separate agreement has already been reached to build a remote-sensing satellite for China and launch it on a Chinese rocket. But the military insist that Brazil's programme must await Brazil's own launcher.



The Amazon basin in mosaic form from INPE. The fine grid of lines at the bottom is the road system in Rondônia. Around it much of the forest has been cut down.

Bitter about media treatment, remote sensing director da Cunha.

Meanwhile, Roberto Pereira da Cunha, director of remote sensing at INPE, still feels bitter about press handling of the dispute that thrust prominence on INPE last April. The project was important because it was the first complete satellite image study of deforestation in a decade. But the message was lost amid controversy over the figures.

"The problem is that everyone likes to do sophisticated things", says da Cunha, "everyone likes to talk about the influence of deforestation on climate and global warming but no one wants to do the dirty work of gathering the data. It is a very trivial job for scientists." Deforestation estimates varied from 44 per cent to the World Bank's 12 per cent, but all were projections from old figures. INPE scientists calculated from a mosaic of 101 Landsat images that in fact 5.12 per cent of the government-defined 'Legal Amazon' had been deforested in recent times (not since 1500 as Sarney claimed — there are large areas of very old deforestation).

Arguments continue over whether deforestation should be related to the Legal Amazon, or to the total area of rainforest or some other number but da Cunha says these are not really important.

Absolute values matter little compared with continuing rates of deforestation. He is now trying to obtain funds to study changes through to 1992 as part of the International Space Year, in collaboration with the US National Aeronautics and Space Administration and the European Space Agency.

Da Cunha stresses that remote sensing has many uses and his group, almost 200 strong, puts much of its effort into research in image-processing and generation as well as applications research and technology transfer. Satellite data have been used to settle legal disputes over whether land is in use or not (a key factor in maintaining ownership), to estimate the areas of flooding of the giant reservoirs and to monitor development projects. And in a more esoteric project, some of da Cunha's group are using satellite data to study the gigantic and enigmatic patterns of lines in the desert at Nacza in Peru, to see if they were drawn according to astronomical principles. □

UNIVERSITY OF SÃO PAULO

The biggest and the best

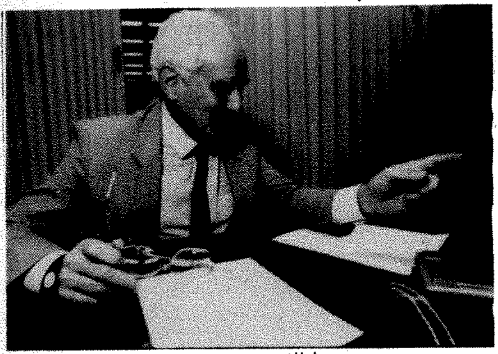
São Paulo

IT is a cruel shock to the senses to arrive in São Paulo on a wet, dark night. All that can be seen is a spinning confusion of freeways, underpasses, missed turnoffs and high-speed drivers who overtake on the inside and cut in front of one with a little flourish. São Paulo is huge; ringed by factories and slums and dissected by an irrevocably polluted pair of rivers. With more than nine million inhabitants, it is the largest city in Latin America and the third largest in the world.

Surprisingly, dawn reveals that São Paulo is also beautiful. It is a hilly city with plenty of green spaces and views and the broken skyline of tower blocks is never monotonous. Out of town — at around the 20-kilometre mark — the city degenerates sharply into shacks and shabby shanty towns, home to five million of the poorest.

São Paulo is the capital of the richest state in Brazil. Its inhabitants add up to less than a quarter of the total population but they generate half the nation's GNP. This one state contains half of Brazil's top eight universities, and best of them all is the University of São Paulo (USP).

The university is a little out of town, scattered over a slope from the top of which São Paulo is seen spreading across the horizon. At the bottom of the hill is a clock tower and the other usual symbols of a university campus and, quite out of place, a two-km-long rowing tank. This splendid facility was apparently built for a Pan-American games that was never held.



Folha de São Paulo

Goldemberg: centre-stage until January.

Ruler of this university for the past four years has been physicist José Goldemberg, a larger than life figure well known both as rector and for his criticism of the government's nuclear programme (see page 374). His term of office ends in January.

The university is big: 35,000 undergraduate students, 15,000 graduate students (half the doctoral degrees in Brazil are taken here), 5,000 faculty and 15,000 support staff. Eighty per cent of students study science, engineering or medicine. Seventy per cent of the faculty hold doctorates, the highest percentage in Brazil.

Goldemberg has been a controversial rector who shook up the university through insisting on increased emphasis on research.

When he took office, the university had few funds of its own and almost all the money for research, even down to journal subscriptions, came from grants. Now 20 per cent of the university's $250 million-a-year income from São Paulo state goes on non-personnel costs — laboratories, computers, libraries and the like.

Goldemberg says that when he became rector he decided to "make great efforts to be in the vanguard. Since Brazil needs modern technology we have to put a lot of emphasis on research and high quality." He says he met resistance.

"How do you put pressure on people who all have tenure?" he asks rhetorically. "You use a complex sytem of incentives — access to money, and better libraries, better communications, computers, sending people abroad . . .". Goldemberg recounts his various temptations and sighs over those who were not ready for them.

"Some areas were not in a position to absorb money. They had no ideas, no contacts. I would tell people to make a list of everything they wanted, then they found they could not make a proper list, they were used to underdevelopment." "People thought I was a bit harsh", he says, "but after the event they thought it was not so bad and even approved of what I had done."

Goldemberg's successor, Roberto Leal Lobo, was chosen by election two weeks ago. As elsewhere, there was heated debate over how much say students and support staff should have in the new 'democratic' election. USP decided on a safe multi-stage election that left the final choice to the professors and, ultimately, the governor.

Lobo is a physicist and was previously vice-rector, but his election was not a foregone conclusion. Running against him were the Secretary of State for Science and Technology (page 371), and half a dozen other university professors. A key issue during the campaign was the university's links with industry. Some candidates were against expansion of industrial involvement, others wanted it to be given the highest priority. Lobo backed a middle way with, he says, "human resources as the first priority, with an overflow to industry. Otherwise we'll just become an industrial research institute."

'Evaluation' was another controversial issue in the election. Many faculty wanted the cosy option of evaluation being left within departments, but Lobo backs the move to more independent assessment. A doctorate is essential now for a staff position and Lobo claims that contracts of non-tenured staff are no longer automatically renewed. Although there is no comparison with the driving pressure of the United States, USP is moving towards a more competitive environment.

Facilities at USP are the best in Brazil and will soon be even better thanks to a $150 million loan from the InterAmerican Development Bank (IDB). The sophistication of the university allows researchers to keep up with international trends to an extent not visible at other Brazilian universities.

Researchers at the Institute of Physics, for example, were quick to replicate experiments demonstrating high-temperature superconductivity. They also jumped in immediately when they heard about cold fusion, but director Ivan Cunha Nascimento says that "after three months we decided to stick with high-temperature fusion!" The institute has a plasma-physics group and a small tokamak, the only one in Latin America. IDB funds have provided for a new molecular beam epitaxy laboratory and two new electron microscopes.

Elsewhere, the Institute of Oceanography is able to run yearly expeditions to the Antarctic where Brazil maintains an all-year-round base. That gives the geologists from the Institute of Geosciences a

---

UNIVERSITY OF CAMPINAS

Technology the driving force

Campinas

THE State University of Campinas, located in São Paulo state about 100 km from the capital, is often described as "second only to USP". But it is not an imitator of USP. From the time it began life in 1966, Campinas chose to give priority to science, technological research and, uniquely, links to the production sector. The first courses it offered were in physics, chemistry and mathematics, set alongside technological projects in optical fibres. lasers and computers. Next came engineering and last of all, in the 1980s, the arts.

Campinas now offers a full range of disciplines. It is very popular and has around 23 applicants for every place, making it more competitive even than USP, although it is only half the size. The campus has a quiet feel, set amid sugar cane fields in the rolling countryside a few miles outside the city of Campinas, the second largest in São Paulo state with a population of three-quarters of a million. Although the university was created at the height of the university expansion boom, it managed to keep to a policy of recruiting only the best staff. Sixty per cent of faculty hold doctorates, which is a very high proportion in Brazil, and around ten per cent are from foreign universities.

Campinas faculty like to list their university's unique features. First, almost half of its

,000 students are pursuing graduate courses. any are themselves teachers on release om other universities all over Brazil, giving pinas the reputation of a 'school for ools'. Second, researchers are encouraged build their own links with industry and en to profit from them. Campinas was the st university to set up a patent office to otect its staff's discoveries (a move which s still found few imitators). Several searchers have set up their own small mpanies. Third, the university has been gressive in buying good facilities.

At the the end of last year, it bought an M 3090, giving it the most powerful supermputer in Latin America. Next, as soon as deral funds are available, will come the ational Synchrotron Light Facility. From e beginning it has had the National Center r Research in Telecommunications.

In 1986 it created a large biotechnology stitute at the stroke of a pen by buying arby Monsanto Corporation's Agricultural esearch Center. Later, it complemented e centre with a Genetic and Molecular ngineering Center to train people for the pected expansion in biotechnology. Now ere is an multidisciplinary programme tred around biotechnology, alongside nilar integrated schemes in computers, fine emicals, energy and new materials. The ctor, Paulo Renato Costa Souza, says that s univerity's philosophy of trying to build tegrated programmes, instead of letting eryone submit individual grants, is "cometely new in the university system". ☐

BUTANTAN

Biomedicine with a bite

São Paulo

Snakes, scorpions and spiders make the Institute Butantan famous. Its serpentarium is São Paulo's most popular tourist attraction and every year thousands of people from all over Brazil send to the institute snakes and other exotic creatures they have found in field or garden.

The snakes are essential for Butantan's function as the main supplier of antivenom in Brazil. Venom is milked from the snakes and used to hyperimmunize horses (the institute keeps 700 at stables outside São Paulo); a specific gamma globulin fraction containing antibodies against the venom is later extracted from the horses' blood. The institute maintains a small hospital, manned 24 hours a day, with a helicopter pad in front of it.

People bitten in the São Paulo region are rushed here — treatment within the first three hours is most effective. Brazil has an impressive array of poisonous snakes and more than 30,000 people are bitten each year.

Snakes are not the institute's only concern. Butantan is essentially a large biomedical research institute joined with a production facility. As well as snake antivenoms, it produces 16 kinds of vaccine. Its 1,300 staff are divided among 20 different departments of basic research and a new Centre of Biotechnology.

Naturally enough, some of its key projects involve improving vaccines. One involves cloning polio virus in vaccinia with the eventual aim of constructing a single-shot vaccine cocktail for polio, measles, hepatitis B, diphtheria, tetanus and whooping cough. Another is to develop a genetically engineered hepatitis-B vaccine, although the institute may decide to buy the technology from abroad. Projects to produce albumin and factor VIII by new techniques are also under way.

Other groups do basic research on venoms (the important vasodilator drug bradykinin was first isolated here), viruses (it is still relatively easy to discover a new virus a day in the rain forest), the genetics of amphibians and reptiles, and the isolation of natural substances from plants and marine animals.

Techniques developed at the institute are transferred free "to anyone seriously interested in production", says the director, Willy Beçak. "We're not interested in profit but to be in the at the frontier", he says; "the idea is for the institute to be an open place for people from universities; often universities are not the right place for transfer to the production sector."

Folha de São Paulo

Willy Beçak and one of his Butantan production workers.

The institute's popularity rose after it opened a 'reagent supermarket' in an effort to counter the effect of import restrictions.

Special permission to import reagents tax-free in bulk, together with a $1 million grant from CNPq, enables Butantan to offer immediate delivery of a range of hard-to-import items. But it is not permitted to duplicate reagents manufactured in Brazil. ☐

---

chance to examine structures in Antarctica to which Brazil was once joined. Overall, the impression at USP is of a university that is only occasionally at the international frontiers but is frequently not far behind them.

But like researchers elsewhere, USP staff are held back by petty import restrictions. Some laboratories — the Institute of Chemistry is one — employ several people simply to do the paperwork. But the delay remains. Ana Clara Schenberg, a yeast geneticist at the Institute of Biomedical Sciences, has been waiting for one piece of equipment for four years. It is already obsolete.

Life is particularly difficult for molecular biologists. Even things such as dry ice are in short supply and items that need to be used quickly — short-lived isotopes, for example — are almost unobtainable. And, worst of all, delay destroys flexibility. "If you need to change your research programme, just forget it", says molecular biologist Bianca Zingales. Everything has to be planned ahead around the import of reagents.

Many highly trained young researchers are now returning from abroad, thanks to earlier government decisions to invest in foreign fellowships, offering the chance to push the university ahead. Unfortunately, the returning researchers often seem quite lost — particularly those who have been at top US laboratories.

Around the campus, young people in various stages of 'returnee's syndrome' can be met. Salete Newton, who returned from a postdoctoral fellowship at Stanford University three months ago, is in the fairly early stages. "You don't know what to do", she says, "you know everything will take ten times longer than in America. There the limit is your imagination, here you are trapped by the limitations of the facilities."

A little later, the returnee struggles to see advantages. "At last I have time to read all those papers", says one. "Maybe it's a good thing that I'm forced to think instead of just rushing onto the obvious experiment", says another. Along comes the thought that one is free.

"I realized I could try some stuff that would be thought too risky over there, the sort of thing you would only do if you are already a full professor", says molecular biologist Fernando Reinach, who has no symptoms of the syndrome after three years back home. Returnees also come to realize that at USP one can attract the very best students of one's own.

The fully recovered researcher avoids the most internationally competitive areas but is busy inviting foreign colleagues for short stays (provided they agree to smuggle restriction enzymes, short-lived isotopes and the like through the Brazilian customs), using BITNET and facsimile machines to keep up, building a group in an area of his or her own, and sending off students for doctoral training abroad. Of course, there are always a few who never recover and just settle back. . . . ☐

OSWALDO CRUZ

Institute earns healthy respect

Rio de Janeiro

THE Oswaldo Cruz Foundation's grounds are ringed with fences, walls and armed guards who harbour deep suspicions about strangers. Presentation of a copy of *Nature* will in no way convince them of one's good intentions. That and the baroque architecture of the 'Moorish Pavilion', set on a hill amid dark trees above, suggests one may have accidentally stumbled on a secret military organization rather than a biomedical foundation.

Later, an explanation emerges. The foundation, on the northern outskirts of Rio de Janeiro, is ringed with *favelas*. A few weeks earlier a couple of men dressed as policemen had come along and persuaded a naive academic to loan them his car for an 'exercise'. They then robbed the bank on the foundation's grounds and vanished (or so the story goes).

J. Pinto

Imposing prospect: the Oswaldo Cruz Institute is important politically as well as medically.

The normally peaceful institute was set up by Oswaldo Cruz in 1900 to produce vaccines to combat local epidemics of plague and yellow fever. It still produces vaccines (like its sister Institute Butantan, page 369) and over the years has gained a reputation as the most distinguished biomedical research institute in Brazil, with a considerable voice in public affairs.

In its grounds is the National Public Health School which trains most of the nation's health administrators. Akira Homma, the institute's director, is clearly proud that the institute helped to write Brazil's new constitution.

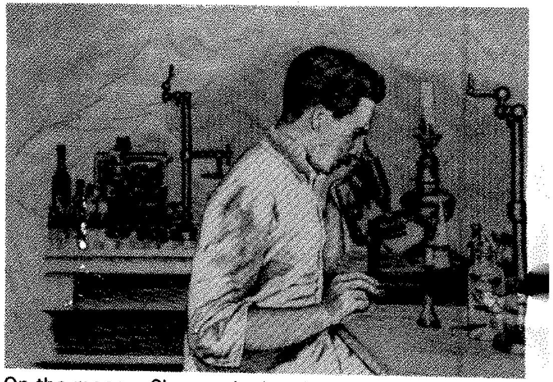
Half the institute's budget comes from the government and a third from the sale of vaccines. Vaccine sales are important, says Homma, because that means "we have our own budget, produced by ourselves which we can invest by ourselves". Production is being built up further with national self-sufficiency the goal. Polio vaccine is still all imported but the institute supplies much of the world's yellow-fever vaccine.

The production facilities aside, the institute feels little different from a university. But the focus is on "endemic diseases and their vectors", research director Carlos Médicis Morel explains, with the link between research and production clearly in mind. The institute's 200 researchers are expected to publish in international journals and to be capable of true international collaboration — "Not the old kind where we have the diseases and they have the technology", says Morel.

Grants from the World Health Organization provide foreign currency and allow some items to be obtained on a 'diplomatic' basis through the Pan American Health Foundation. The result is a miracle in Brazil — Morel is able to order short-lived isotopes by telex from abroad and see them delivered in 24 hours. "There is a fight for every microlitre", he says.

A new biotechnology department is to combine research and pilot plant production and will concentrate on diseases transferred by the blood — including AIDS, malaria, syphilis and, of course, Chagas' disease.

Chagas' disease, named after the former director, is still both an important research topic at the institute and a major health problem in Latin America. As many as 10–12 million people are affected. Modern medicine has not cured the illness but has brought new modes of transmission. In Brazil, 20,000 people a year are infected through contaminated blood transfusions, perhaps more than the number infected by insect bites. Despite the scale of the problem little was done until AIDS arrived. Previously, poor people were commonly selling blood to private transfusion banks. That is now illegal (thanks in part to the institute's lobbying). But the change has come too late for haemophiliacs. Sadly, 70 per cent of them carry the AIDS virus.



On the money: Chagas depicted on a 10,000 cruzados banknote.

Morel, when not wearing his research director's hat, runs a group developing DNA probes for diagnosis of Chagas' disease. Samuel Goldenberg, a young molecular biologist returned from Paris, is trying a different approach, using recombinant antigens.

Diagnostic kits in use now cross-react with antigens of other diseases. His group has cloned several *Trypanosoma cruzi* surface antigen genes, and one has good potential for use in a test kit.

Goldenberg has a fine sense of the differences between laboratories here and in Paris and the pains and joys of working in Brazil. His field is the molecular biology of development.

"Elsewhere", he says, "I would probably work with *Dictostylium*. Here I work with trypanosomes. My main interest was in basic biology. but now we may have an application for our work. When you feel your science is being used for something useful its very very good."

His group has found factors that trigger the switch from the nonreplicative stage of *T. cruzi* to the replicative stage and is looking for enzymes important in the differentiation process. If enzymes unique to the trypanosome can be found, therapy with specific inhibitors may be possible.

Goldenberg's laboratory is overcrowded to bursting point. The corridors are so full of equipment that if two people meet they have to work out a way of backing into the remaining spaces in order to get past one another. If three or more people meet, the moves become just too complex — it is better just to return to one's room.

Goldenberg says that he sometimes "gets really fed up with the difficulties", that "he cannot hire new staff but is simply sending people abroad", that the strict importation rules mean that he is "treated like a smuggler" and that foreign journals come by sea, "three or four months late". But, he says, "the ambition here is not to publish, publish, publish as in the United States — we do want to publish but the main goal is to train more people".

In mid-October, Goldenberg was busy trying to organize the 16th Annual Meeting on Chagas' disease and leishmaniasis, due to begin a few weeks later at a resort hotel. Six hundred participants were expected. The organizers pay for research students' accommodation, "otherwise the students won't be able to go", says Goldenberg, "and its a good opportunity for them to meet people, find a place to do a postdoc. But it is a hard task because we cannot find any funds!" When last seen, Goldenberg was listening to the manager of the hotel shouting, "When will you send the money. When will you send the money?" over the telephone. In Brazil there usually seems to be some way to fix the impossible — no doubt the conference went well. □

SCIENCE MINISTER

Informatics law and disorder

São Paulo

DÉCIO Leal Zagottis is Secretary of State of the Special Secretariat for Science and Technology of the President of the Republic of Brazil. Had he taken office last year rather than this, he could have done the same job and been simply Minister of Science and Technology; the cumbersome title is the result of a political battle for control of the ministry during the first few months of this year.

The opening broadside came in January with the sudden announcement that the Ministry of Science and Technology was to be abolished and its functions shared out among other ministries.

At the same time, the president agreed to wrenching cutbacks that reduced science and technology budgets by half and would have led to the dismissal of 40 per cent of research staff at CNPq institutes. But the surprise attack was motivated not just by the desire to save money; in the vanguard of the charge were those who opposed the ministry's controversial informatics law.

As it turned out, the abolitionists did not prevail. Congress rallied to the ministry's cause and three months later it was back, albeit under a new title which left it with a little less weight than a full ministry. And Zagottis, whose support for the informatics law is well known, was appointed to head the new agency.

The controversial law was passed in 1984 to foster the local production of computers, software and peripherals by reserving the Brazilian market for 'national' companies, that is, those that are Brazilian-managed and at least 70 per cent Brazilian-owned. The law has been bitterly opposed, both by the United States which sees it as restricting access by its giant computer companies, and by local industry which sees it as forcing up its own costs by making it buy higher-priced lower-quality Brazilian equipment.

Zagottis, a professor of engineering at the University of São Paulo, entertains no doubts about the effectiveness of the informatics policy. Brazil began at the same level as Mexico, but Brazil now has an industry of 60,000 employees, twenty times larger than Mexico's, and supplying over three-quarters of the nation's computers. "Informatics is connected to so many other fields, it is a strategic economic area which must be protected", he says. Protection is intended to come to an end in the early 1990s, to ensure that an inefficient monopoly does not develop.

Zagottis does not think the same policy will work in other high-technology areas. "You cannot have a market reserve policy for biotechnology", he says, "because you cannot do reverse engineering in biotechnology." In other words, while it may be possible to clone an IBM by 'reverse engineering' (IBM engineers might call it 'copying') it is not possible to clone a genetically engineered drug.

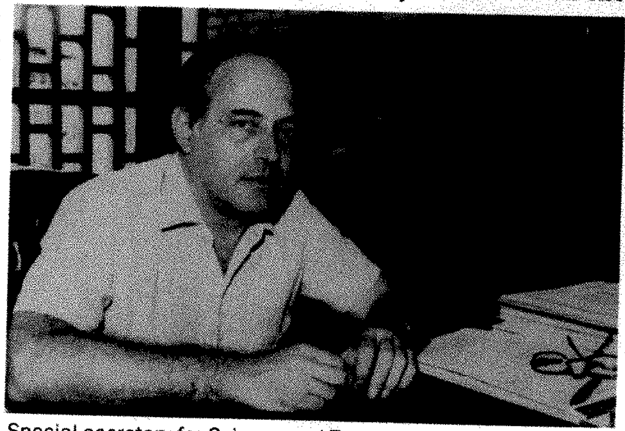
The immediate threat to the informatics law was nullified by the revival of the ministry, but the damage to the science and technology budgets could not be so easily repaired. For almost three months of turmoil, there had been no one to fight for science and technology. Some research institutes, such as the National Institute for Amazonian Research (INPA), that are directly attached to the ministry saw their budget appear in one agency, disappear, appear in another and then disappear again. The result is that they still do not have proper budgets for 1989. Massive cuts for the National Research Council, CNPq, and for the project research agency, FINEP, cannot now be fully restored.

Although it is too early to say what may happen after a new President of Brazil takes office early next year, Zagottis expects that the government will have no long-term investment capacity in the next few years. His solution is to turn to the World Bank and the InterAmerican Development Bank (IDB) to tide Brazil's scientific enterprise over the next next few years. Two big loans are under negotiation: one is a World Bank loan of $330 million to continue the Programme of Support for Scientific and Technological Development (PADCT), the other an IDB loan of $1,000 million over five years to support an integrated science and technology plan.

Zagottis says the idea is to use the money to "allow construction of new buildings for research centres, new laboratories and equipment and to train researchers and technicians". The World Bank is, however, not especially pleased with the handling of funds loaned to Brazil for PADCT I, six years ago. An official team sent to examine progress reported at the end of 1988 that if difficulties delaying the projects "are not solved urgently, they may also create serious difficulties in the renewal of the PADCT loans". Sluggish administration, "excessive" and "unjustified" delay in importation procedures, and the "enormous devaluation of allocated resources due to the current inflation rate if the money cannot be spent very quickly" were the principal complaints.

The importation delay for foreign equipment and materials is a terrible problem. Four-year delays are not uncommon. Zagottis claims that a new law will soon complete changes already under way and ease the import problem. Responsiblity for import procedures is being devolved to big universities from CNPq, which was exceedingly slow in handling requests. But there are, as Zagottis says, "problems lower down the hierarchy"; the requests must still pass through CACEX, the import control agency, whose bureaucrats mete out the same treatment on imports worth $100 or $1 million and insist on evidence that there is no Brazilian substitute.

But imports are just an irritant compared with the fundamental problem of lack of investment. Brazil spends only 0.7 per cent of GNP — a sum of $2,500 million — on science and technology, as against the 2.5–3 per cent spent by the industrialized countries ($150 million in the United States). Zagottis points out that 80 per cent of the money spent by Brazil on science and technology comes from the government, a far higher percentage than elsewhere. If Brazil can boost industry's contribution, then 3 per cent of GNP might be possible for Brazil too. Zagottis backs a short-term rise to 1 per cent of GNP by the government, followed by a steady series of small rises, always a little above the rise in GNP. The first goal, he says, is 2 per cent by 2000.



São Paulo

Special secretary for Science and Technology Zagoittis supports reserving the Brazilian market for nationally produced computers.

For this to happen, a national plan is needed as well as political stability, not something Brazil seems set to enjoy. Increases in investment by industry will only come from a well thought out programme of tax incentives. At present, it is more profitable for industry to license foreign technology than develop their own But a failure to act could jeopardize what has been achieved so far. A key strategy has been to send people abroad for advanced training — that is where a large part of CNPq's money goes. As Zagottis says, "There are 7,000 students taking PhD courses outside Brazil; if they don't have a place to come back to they will leave Brazil permanently" and the effort will have been wasted. ☐

GRANTS AND SCHOLARSHIPS

Finance from start to finish

Rio de Janeiro

FINEP, the Agency for Financing Studies and Projects, is an unconventional mix of a conventional research foundation and a conventional development bank. In principle, this gives it a unique power to take a project from the basic research stage, when a government grant is required, through to the development stage when venture capital or low-interest credit becomes important. In practice, things do not work out quite so neatly: FINEP finances a heterogeneous brew of projects, all at different stages, ranging from university research on AIDS to an industrial company's attempt to develop the first fully Brazilian automobile.

FINEP is one of the few federal agencies to have avoided the move to Brasília, something which clearly pleases its staff. Its offices are in downtown Rio de Janeiro.

Support for basic research comes principally through FINEP's role as executor of the National Science and Technology Development Fund (FNDCT), worth $107 million in 1987. The fund provides for infrastructure, new buildings and new equipment. Significant extra help comes through $180 million of World Bank funds, most of it matched by Brazilian funds, in the Programme of Support for Scientific and Technnological Development (PADCT). Grants are given to support projects, to upgrade and build new facilities and to support university graduate courses. Support for individual researchers is left to the National Research Council, CNPq.

"Earthquakes and turmoil" is how 1989 was described at FINEP. Thanks to the savage cuts of the Summer plan and the temporary disappearance of the Ministry of Science and Technology, to which FINEP is answerable, the agency will be lucky to receive 60 per cent of its 1987 budget. The World Bank has also been frank in its criticism of the slow progress in giving out PADCT funds. Of the $180 million loaned to Brazil in 1983, less than half had been disbursed by 1989. Import regulations and excess bureaucracy — little of it of FINEP's making — have been the major problems.

FINEP claims a good track record. When it was set up in 1967 to develop Brazil's engineering industry, there were very few companies, foreign or Brazilian. According to João Luíz Coutinho de Faria, president of FINEP, "twenty-two years later we have 200 companies; most are Brazilian with an annual turnover of $1,450 million".

FINEP has 700 staff, more than 100 with doctoral or masters' degrees, and last year supported 1,840 projects split almost equally between scientific research and technological development.

Coutinho de Faria points out that demand for the technological component was more than $1,000 million last year. He hopes to see FINEP's funds return to their 1987 level of $300 million next year and climb quickly to the $800 million mark. □

CAPES

Supporting graduates by algorithm

Brasilia

Postgraduate programmes throughout Brazil are coordinated by a Ministry of Education agency called CAPES; not surprisingly, few know the agency by its lengthy title of "Coordinating Agency for Advanced Training of High-Level Personnel". CAPES gives grants and fellowships to 14,000 students at Brazilian universities and to 2,000 students in North America and Europe.

Overall, CAPES provides backing for 700 graduate courses; two-thirds of all the courses in Brazil. It also runs a programme to help build up institutions so that they can offer new courses.

The graduate-training system grew rapidly in the 1970s during the expansion of the university system. At that time, many young and inadequately-trained staff obtained jobs. Today, the boom is over but there are still many unproductive faculty and graduate courses are of very uneven quality. CAPES makes sure it helps the good courses but is sometimes criticized for not being tough enough on the bad.

CAPES' director, José Ubirajara Alves, says that graduate courses are now the "best-evaluated sector in the science and technology system". He is a rare type in Brasilia, describing himself as just a "technician" who has come up with an "algorithm" to ensure that money goes to the courses that deserve it. In fact, Alves is a very well-respected mathematics professor with plenty of experience of starting graduate courses from nothing. When he joined the university at Fortaleza in his home state of Ceará in 1965 he was the only person on the staff with a doctorate (from the University of California, Berkeley). He established its first graduate course — the first at a university north of Brasilia. Fortaleza now has twenty courses.

Alves' algorithm takes into account the standard of the course, the numbers and types of professors and students, and the area (some types of research are more expensive than others). When the calculation is complete the budget goes to the university to provide for a quota of students, selected by the university. □

Fast forward for grants

São Paulo

When scientists complain that the National Research Council (CNPq) is too slow, or too bureaucratic, or too opaque, or too arbitrary, they often end by saying, "Why can't it be like FAPESP?" FAPESP is São Paulo state's own research foundation, receiving by law 0.5 per cent of state income each year to spend on scientific research.

FAPESP is fast: it normally makes decisions on grants within ten weeks of application, less than half the time required by CNPq (or by US NSF).

To ensure openness, applicants are given as much information about the progress of their grants as needed, a job which keeps a couple of secretaries busy full time. And once a grant is given, FAPESP will help to compensate for changes in exchange rate that push up the cost of imported materials. The foundation runs on 50 staff, against CNPq's 1,000.

Alberto Carvalho da Silva, FAPESP's director, is modest about the foundation's reputation, pointing out that CNPq has a budget twelve times as big as FAPESP's $42 million, and has to deal with unexpected cuts and political uncertainties. But he is critical of CNPq's staff numbers, saying that there are so many employees that it has to create something for them to do. Carvalho da Silva has been a victim of the workings of bureaucracy himself; he was purged by the military from his university post in 1969.

FAPESP's operations are much the same as those of research councils everywhere. Support goes to scholarships (not more than 50 per cent of the total), research awards, a small number of large long-term projects (most recently, support for participation in BITNET), visiting professorships, publications, meetings and so on. One novel programme provides 500 scholarships a year to encourage students to move into research by providing support for a pre-graduation research project.

Expansion and change are on the way. The new state constitution increases FAPESP's budget to one per cent of state tax income and gives it new responsibility for the support of technological research. Until now, 90 per cent of the budget has gone to basic research at the universities. In the future there will be a new commitment to the private sector on training and pre-competitive research. "Thus far, we've been run by scientists", says Carvalho da Silva, "now we'll be looking for international advice. We will use our contacts with the United States and the United Kingdom to look at science parks and adapt their models to our realities". □

RESEARCH SUPPORT

The council has the last word

Brasilia

It is a mean trick to arrive at the headquarters of the National Research Council (CNPq) after several weeks of accumulating complaints from Brazilian scientists about their parent research organization. CNPq is too cumbersome, they say, it is supposed to handle import procedures but everything takes years, travel grants arrive after conferences are over, foreign collaborations founder in paperwork, and grants are spread too thin, or go to foreign scholarships so that nothing is left for those at home.

And yet more, CNPQ swallows you up complains one University of São Paulo researcher, “if you criticize them, they say ‘come and help us’, and you end up being involved in all those difficulties too”.

Guilherme Brandão, Special Assessor for International Cooperation at CNPq, is a pipe-smoking meditative type who only occasionally shows signs of mild irritation at some of the more unreasonable behaviour of scientists. CNPq is not, in any case, a complete master of its own destiny, but has to weather all kinds of political storms and bureacratic meddling.

Science lives in a difficult environment. “Science and technology are not thought of as a high priority”, says Brandâo, “we are pressured by so many other things we need to solve, we have immediate problems in health and nutrition and so on”. And because there is no tradition of research and development by industry (expenditure on research by industry is just 5 per cent of the total), science is totally dependent on the government. “When there is a government financial crisis, we suffer badly”, says Brandão. One of those crises arrived earlier this year when budgets were cut by half and, for a short while, it seemed that some 40 per cent of the staff of CNPq's research institutes might be without a job.

To summarize, CNPq is a research council just like others elsewhere, except that along with its grants programme it has eleven research institutes (see page 357) and a large scholarship programme. It has been very powerful, with full responsibility for science and technology policy. But that responsibilty went to the Ministry of Science and Technology (now the Special Secretariat for Science and Technology) in 1985. CNPq has never really relinquished its claim to the area and despite lacking an official mandate, continues work at its Centre for Policy Studies.

If scientists complain of tardiness, they are perhaps insensitive to CNPq's scale. Each year, 40,000–50,000 applications for grants come in to CNPq's offices (including travel grants and so on), along with over 100,000 applications for scholarships. Suitable reviewers have to be found for each application, CNPq can provide for a third of the applicants in each category.

CNPq employs 1,000 staff but even so Brandão says that sometimes “the amount of paperwork drives us crazy here”. The system is to be rationalised next year. Instead of four fixed decision periods a year, a system which can never generate a decision in less than 4–5 months, CNPq will deal on a once-a-year basis with some things (scholarships, for example) and continuously with others that need immediate decisions (such as travel grants). That change should do away with a substantial fraction of the complaints of CNPq's inflexibility.

CNPq's scholarship programme is big, too big says critics, who think more of the resources should be directed to ongoing research rather than training. Ten year ago there were just 5,000 research scholarships in total. Today there are 30,000 inside Brazil and 3,500 overseas, part of a definite policy that top priority should go to human resources. But the number abroad will lessen next year as people return and efforts are made to save foreign currency. Inside Brazil the number will increase to provide 44,500 places. A scholarship is not riches — a doctoral student receives around $600 a month — but thanks to “a very great joint victory of CNPq and CAPES”, the amounts are tied to staff salaries so providing compensation for inflation.

On the extraordinary difficulty of importing equipment and reagents for research, Brandão wearily says, “Yes, we understand the community's complaints. But sometimes they complain in the wrong place”. CNPq is caught up in a much vaster bureaucracy.

All imports must pass through CACEX, and CACEX is essentially an instrument of foreign policy. It is necessary to show that no similar Brazilian product exists but ‘similarity’ is often a “complicated business”, says Brandão. Next a pro-forma invoice is necessary, then “when you send this to CACEX they may have a problem with foreign currency and freeze everything”.

While the difficuties are undoubtedly real, some problems may remain at CNPq. According to the World Bank, FAPESP, the São Paulo-state research council (see opposite) takes from “six months to a maximum of one year to import equipment”, while CNPq takes “one and a half to two years”. And CNPq took “at least 45 days to log in importation requests” (it has since improved).

CNPq has to spend a lot of time fighting off arbitrary decisions from elsewhere. Brandão relates how in January the government suddenly decided that money sent abroad for training grants should be exchanged at the tourist rate rather than the official rate, immediately cutting the grants' value by more than half. In the ensuing havoc, many students decided not to take up their scholarships. The decision was reversed only a few weeks ago.

One complaint which Brandão clearly feels unfair is that Brazil is trying to shut out foreign researchers or limit their access to the Amazon. Brandão says that 99 per cent of foreign expeditions (of which there are 30–40 a year) are approved, but there have to be formalities to ensure that an expedition will not intrude on Indian or private land and so on. Collaborative programmes, of which there are thousands, are organized through Brazilian counterparts. Brandão says the system ensures that Brazil obtains some benefit from research conducted here.

CNPq is looking to the future and looking for innovative ways to boost research investment by industry. It is not easy because in many industrial sectors a foreign licensing agreement captures a sure product while home development involves risk. But in other, newer sectors, foreign companies do not want to license their technology. CNPq is trying to get Congress to adopt flexible tax incentive strategies. In the meantime it is introducing a new programme of human resources in strategic areas (biotechnology, new materials and the like), to support the training of personnel in any institution, private or public, provided it is tied to a long-term research and development programme. The goal is to have 3,500 people in the programme by next year. □

CAPITAL CITY

Back to the future

Brasilia, the futuristic city of the 1950s, is laid out in the shape of a gigantic bow with its central arrow an enormous, thousand-yard wide avenue that, at its tip, juts out into an artifical lake. Along it, at great intervals, are the television tower, various monuments, the cathedral, the double row of identical, rectangular blocks containing the ministries, and then Congress and the Supreme Court.

The bow is a curving set of parallel roads along which are organized the city's ‘sectors’: the hotel sector, the banking sector, the cultural sector, the hospital sector, the embassy sector, the sector of individual housing . . . and so on. The great unifying architectural plan continues to inspire in areas of astonishing simplicity of design, where traffic flows swiftly past rows of simple, white concrete apartment blocks raised on stilts to allow clear sight lines. Elsewhere, the road plan remains but the city has filled in a medley of styles. CNPq has its offices in the sector of “autarquias” — autonomous organizations. □

BOMBS AND BIOTECHNOLOGY

Some projects from the past

São Paulo

WHEN the first wave of oil price surges arrived in 1973, Brazil reacted with two new and massively expensive programmes to reduce dependence on energy imports One was intended to provide electricity from nuclear power, the other to substitute sugar alcohol for petroleum Both projects were creations of a military government which could exercise strong central control over resources Fifteen years later, both projects are floundering as they face markets which demand a more rational allocation of resources

Opposition to the nuclear programme was strong from the start "It was very clear that nuclear energy for electricity production was a complete misconception," says University of São Paulo (USP) rector, José Goldemberg, a well-known critic of Brazil's nuclear plans, "seven billion dollars gone with little to show"

A small US reactor is in operation but the agreement signed with West Germany to build eight reactors has yet to create one operating plant The programme, "was slowly delayed but never cancelled," says Goldemberg, "scientists opposed it because it involved very little technology transfer Industrialists who lost opportunities because of support for the programme opposed it " Last week, West Germany extended the agreement with much reduced goals But the situation may change again under a new president Goldemberg believes that "in a democratic society it will become increasingly difficult to justify the expenditure against social programmes" The sugar alcohol programme appears very much more successful

Four million of Brazil's 12 5 million vehicles run on alcohol produced from fermentation of sugar and massive reductions in petroleum imports have been achieved But the programme is in serious economic and political trouble Brazil has found large oil reserves of its own Sugar alcohol is proving more expensive to produce than petroleum, the distilleries are producing huge quantities of polluted water, and subsidies for sugar-cane growing distort local economies by encouraging farmers to grow cane even when vegetables are in short supply

These, at least are the arguments advanced by the state petroleum industry, which wants to see petrol roll back some of alcohol's advance With the backing of the Ministry of Mines and Energy, the petroleum industry has scored well in the media war The sugar alcohol industry, backed by the Ministry of Industry and Commerce, is in retreat but it too claims that subsidies disguise the true state of the petroleum industry The battle of the subsidies will be fought between the two ministries under the new president and in the minds of consumers, who must decide which kind of car to buy

One factor in the battle is the scope for improvement in sugar alcohol production Waste treatment is already possible and biotechnology may offer much more Little sustained effort has gone into the improvement of yeasts Genetic engineering can permit new substrates to be used, such as starch which yeast cannot normally degrade In a clever piece of engineering, Ana Clara Schenberg at USP has already constructed yeast strains carrying α-amylase genes from mouse, plus other yeast genes introduced by conventional genetics and shown the new strain can produce ethanol directly from starch While the project is at the laboratory stage, it suggests that it is too soon to begin writing off sugar alcohol ☐

Parallel secrets

FEARS that Brazil is intending to develop nuclear weapons in secret are fading with the return of democracy

In 1987, after the disppearance of the military regime, a secret 'parallel' nuclear programme emerged with the announcement by President José Sarney that the navy had succeeded in low-level enrichment of uranium fuel The work was carried out at the Institute for Energy and Nuclear Research (IPEN), adjacent to the USP campus

The aim of the programme is not a bomb, but fuel for a nuclear-powered submarine Although Brazil has no enemies and the expense of developing nuclear submarines seems superfluous, the offical reply is that the project will take 20 years and by then Brazil will be a great power The navy was much impressed by the performance of nuclear submarines during the Falklands conflict

As the 'parallel' programme went public, demands increased for greater accountability of the military's activities The new constitution prohibits the development of nuclear weapons and gives Congress control over the nuclear energy programme But the constitution left possible the development of 'peaceful' nuclear explosives The first steps towards civilian control came last year when the government established a Superior Council for Nuclear Energy as an advisory board to the president Goldemberg was one of three civilian scientists on the council, which includes 17 ministers Although the meetings are not frequent, Goldemberg says that "the president attends and it is now very difficult to do anything under cover"

Next step could be a congressional committee with oversight of military programmes Brazil would then be close to the certainty that the submarine programme could not be diverted towards manufacture of a bomb ☐

. . . and future

Rio de Janeiro

IF new styles of collaboration between the universities and industry are what is needed to boost investment in science, then the Federal University of Rio de Janeiro (UFRJ)'s island may be the place to look for future trends Here Antonio Paes de Carvalho has confidently launched a new biotechnology venture, Bio-Rio, which links industry, the Oswaldo Cruz Foundation and the university Within ten years, Paes de Carvalho confidently predicts there will be 70 companies here, employing some 4,500 people and enjoying $250 million in sales

Paes de Carvalho is a cardiac electrophysiologist, an unusual skill from which to move into biotechnology But in 1980, he says, he was director of the Institute of Biophysics at UFRJ and became "worried about the financing of research" As there were experts in tissue culture and molecular biology in the institute, Paes de Carvalho thought biotechnology might be a good bet

So with the belief that "you have to do things yourself", he set up a non-governmental, biotechnology foundation close by. The foundation will operate central research facilities and allocate surrounding land, at a nominal cost, to private enterprise The central facility will offer specialized services (for example, peptide and nucleotide sequencing and synthesis) and provide 'incubator' space where projects can be developed

In October the central laboratory facility was being carved out of the vast kitchen (conveniently complete with cold storage rooms) of an abandoned university cafeteria This month, the first two companies are moving into their incubator space

There are other biotechnology intiatives elsewhere but none based on direct interaction between industry and university "The biggest fight," says Paes de Carvalho, "is to convince the university that this kind of industrial proximity is OK'. The university authorities at first rejected the project, but were eventually persuaded with help from the rector — as he was a communist he apparently could not be accused of selling out to capitalists

The government has invested $3 million in Bio-Rio, and industry another $1 million Paes de Carvalho expects industry to provide another $100 million over five years, encouraged by big incentives from the National Development Bank Critics say the plan's weakness is the shortage of qualified researchers, most of then in universities and without interest in links to industry

But Paes de Carvalho believes that he can engineer the interaction between university and industry so that it will be painless for researchers and not threaten basic research ☐

An Invitation to Explore the Frontiers of Knowledge

THE SOCIETY FOR SCIENTIFIC EXPLORATION

As science has developed, it has become increasingly compartmentalized. This may make the operation of each discipline more efficient, but we run the risk that the profession may not be responding to challenges that do not fit neatly into the matrix of present-day science.

The international SOCIETY FOR SCIENTIFIC EXPLORATION was founded in 1982 to provide a professional forum for the presentation, scrutiny and criticism of scientific research on topics outside the disciplines of conventional scientific activity.

The Society holds an annual meeting and publishes both a newsletter (The Explorer, two issues/yr) and a journal (Journal of Scientific Exploration, published in collaboration with Pergamon Press, two issues/yr).

The following articles were published in recent issues of the Journal of Scientific Exploration:

- *New Ideas in Science*, T. Gold, Cornell University.
- *Towards a Quantitative Theory of Intellectual Discovery*, R.G. Fowler, University of Oklahoma.
- *The Nature of Time*, Y. Terzian, Cornell University.
- *Engineering Anomalies Research*, R.G. Jahn, B.J. Dunne, and R.D. Nelson, Princeton University.
- *The Strange Properties of Psychokinesis*, H.Schmidt, San Antonio.
- *Archeological Anomalies in the Bahamas*, D.G. Richards, Atlantic University
- *An Analysis of the Condon Report on the Colorado UFO Project*, P.A. Sturrock, Stanford University.

You are invited to participate as an Associate of the Society for Scientific Exploration Associates receive both the Explorer and the Journal of Scientific Exploration Associates are also invited to attend the Society's annual meeting, and to submit articles for either the newsletter or the journal (All journal articles are peer-reviewed) To become an Associate, please send the completed form below, together with a check in the amount of 35US$, to the Secretary of the Society

Professor Laurence W Fredrick
Dept of Astronomy, University of Virginia

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously

Nature is an international journal covering all the sciences Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields Please write clearly and simply, avoiding unnecessary technical terminology *Nature's* staff will edit manuscripts to those ends if necessary Contributors should check their proofs carefully

Because of the competition for space, many of the papers submitted for publication cannot be accepted For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words

CATEGORIES OF PAPER

Review Articles survey recent developments in a field Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator Length is negotiable in advance but must not exceed six pages of *Nature*

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications

Articles may contain a few subheadings of two or three words The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows There should be fewer than 50 references

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature* The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study Letters should not have subheadings or more than 30 references

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research Some are commissioned, most are unsolicited They are normally between one and four pages of *Nature* in length

News and Views articles are intended to inform non-specialist readers about a recently published advance Suggestions should be made to the News and Views Editor Illustrations are welcome Proposals for meeting reports should be agreed in advance

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature* Priority is given to contributions of less than 500 words and five references Figures are welcome

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only Four copies are required, each accompanied by lettered artwork Four copies of half-tones should be included Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number Original artwork should be unlettered Ideally, no figure should be larger than 28 by 22 cm Figures with several parts are permitted only if the parts are closely related, either experimentally or logically Suggestions for cover illustrations, with captions, are welcome Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published

Colour Artwork. A charge of £500 a page is made for 4-colour figures Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible The figure should be described first, then, briefly, the method Reference to a method described elsewhere is preferable to a full description Methods should not be described in detail in the text

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate) Text should not be included in the reference list References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65) The first and last page numbers should be cited Reference to books should clearly indicate the publisher and the date and place of publication

Abbreviations, symbols, units and Greek letters should be identified the first time they are used Acronyms should be avoided as much as possible and, when used, defined Editors will shorten words if necessary In case of doubt, SI units should be used

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named

Acknowledgements should be brief Grant numbers and contribution numbers are not allowed

***Submission.** All manuscripts may be submitted to either London or Washington They should not be addressed to editors by name Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT)*

Upper bounds on 'cold fusion' in electrolytic cells

D. E. Williams*, D. J. S. Findlay†, D. H. Craston*, M. R. Sené†, M. Bailey†, S. Croft†, B. W. Hooton‡, C. P. Jones*, A. R. J. Kucernak*, J. A. Mason§ & R. I. Taylor*

* Materials Development Division, † Nuclear Physics and Instrumentation Division and ‡ Nuclear Materials Control Office, Harwell Laboratory, UK Atomic Energy Authority, Didcot, Oxfordshire, OX11 0RA, UK
§ Reactor Centre and Centre for Fusion Studies, Imperial College, Silwood Park, Ascot SL5 7PY, UK

Experiments using three different calorimeter designs and high-efficiency neutron and γ-ray detection on a wide range of materials fail to sustain the recent claims of cold fusion made by Fleischmann *et al*[1] and Jones *et al*[2]. Spurious effects which, undetected, could have led to claims of cold fusion, include noise from neutron counters, cosmic-ray background variations, calibration errors in simple calorimeters and variable electrolytic enrichment of tritium.

RECENT publications[1,2] reporting electrochemically induced nuclear fusion, at room temperature, have aroused great interest. The signatures reported are excess heat output, neutron emission and tritium generation from cells with palladium cathodes[1], and neutron emission alone at a much lower level from cells with titanium cathodes[2]. Conventional nuclear physics predicts that fusion between light nuclei requires either very high temperature (as in a tokamak) or unusually close proximity of the two nuclei (as in muon-catalysed fusion). The calculated fusion rate at the internuclear separation in the deuterium molecule (0.74 Å) is $\sim 3\times10^{-64}\,s^{-1}$ (ref 3), so the rates reported in ref 2 ($\sim10^{-23}$ d-d-pair^{-1} s^{-1}, d is deuteron) are not easy to understand in the context of the known interstitial-site separations (~3 Å), even more so when it is realized that this rate is a severe underestimate because of incomplete deuterium loading in titanium (see Materials characterization section). The reaction rates reported in ref 1 are even more difficult to understand[4], and the existence, despite strong arguments to the contrary (ref 5, for example), of an unknown mechanism, which results both in an extraordinary enhancement of the reaction rate and a suppression of the normal nuclear-reaction channels, has been postulated.

In the first reports of the electrolytic cold fusion effect it was stated that the effect is not consistently reproducible, and that it both takes some time to appear and that it may subsequently disappear. Because electrochemical phenomena can be sensitively affected by the state of the surface, some irreproducibility is not, in itself, surprising, and other recent reports (refs 6-8, for example) give well documented accounts of failures as well as successes (R. A. Huggins and A. J. Appleby, Workshop on Cold Fusion, Santa Fe, May 1989) in observing the claimed effects. The clear lack of reproducibility necessitates significant replication, with controls at least equal in number to the number of tests, if positive results are to be viewed with confidence, and exploration of many different, well characterized, material and electrolyte combinations. Particularly, the timescales and achievable concentrations for electrolytic loading of deuterium into palladium and titanium, the quantities of hydrogen 'impurity', and the species detectable by surface analysis of used cathodes ought to be determined.

Calorimetry

We used three types of calorimeter. First, we built calorimeters of size and design similar to those used by Fleischmann *et al* (ref 1 and M. Fleischmann, personal communication) (Fig. 1). We found these to be inaccurate instruments with some very subtle sources of error which it is necessary to appreciate and analyse in detail. We used sixteen such cells, containing different-size cathodes (1-, 2-, 4- or 6-mm Pd rods) and different electrolytes (0.1 M LiOD, 0.1 M LiOH, 0.1 M NaOD or 0.1 M NaOH). Figure 2*a*,*b* shows the results obtained for a typical cell. An immediately evident characteristic is the sloping baseline, with the sawtooth pattern a consequence of the regular refilling of the cell. The baseline slope can be quantitatively accounted for by a variation of the calibration constant, *k*, with the level of liquid in the cell. This is a result of radiative losses through the vacuum jacket[9] and conduction up the glass inner wall of the cell[10] (see Fig. 2 legend). A consequence of the sloping baseline is that any calibration is only valid for a particular liquid level. We regularly refilled these cells to a reference level at which the calibration had been performed. We calibrated the cells with the heaters before the electrolysis was started and again much later in the run, during the electrolysis, as is evident in Fig. 2*a* (see Fig. 1 legend for details of the calibration procedure). There was no statistically significant difference between the different calibration sets, so all data were combined.

Figure 2*c* shows results for two of the calorimeters at the calibrated liquid level, in the form of percentage excess of apparent output power over the Joule input power. There was apparently an endothermic period at the beginning of the run, whose duration increased with cathode diameter. We speculate that this was due in part to poor stirring of the solution during hydrogen uptake by the cathode which caused a temperature gradient in the cell (gas is not at first evolved at the cathode and the larger diameter cathodes were shorter, to keep a constant surface area). An analogous effect at the start of the electrolysis was reported by Lewis *et al*[8], who showed that the apparent heating coefficient of a similar cell varied during the first part of a run. Because of this effect, we excluded the first 10,000 minutes of data from each cell when calculating the statistics. Table 1*a* shows the mean absolute power deviation for each cell and the standard deviation in this value. The standard deviation for all of the H_2O cells was not significantly different from that of the D_2O cells (*F* test, 1% level) so that the data from all of the cells can be used to estimate the error $\sigma = 0.048$ W (that is ±5-10%). A more detailed analysis of this error[10] showed it to be largely determined by the variability in the liquid level after refilling the cell, but also with a contribution from unquantified variations in the heat loss by conduction up the calorimeter wall to the air above the water bath. Compared with these errors, effects that resulted from temperature gradients inside the cells were minor. The design used here varied from that in ref 1 in that the glass sleeve that supported the calorimeter and which was in direct contact with the inner wall, provided a large area of thermal contact with the water bath, and thus reduced the effect of the ambient temperature variations.

As we expected, occasional points from both H_2O and D_2O cells lay outside the 'control limits' of $\pm2\sigma$ (Fig. 2*c*). No points lay outside $\pm3\sigma$. No cell showed two or more consecutive points outside $\pm2\sigma$, and the number of points lying above the control limit in the D_2O-cell experiments was no different from that in the H_2O-cell experiments Therefore, we conclude that, within the experimental error, there was no significant anomaly in the behaviour of the D_2O cells compared with that of the H_2O cells If, however, the mean power deviation (Table 1*a*) for all eight of the D_2O cells (+9 91 ± 0 47% or 0 021 ± 0 004 W, mean Joule input 0 96 W) is tested against that for all eight of the H_2O cells (−2 46 ± 0 72% or −0 018 ± 0 004 W, mean Joule input 0 81 W for LiOH cells and 0 61 W for NaOH cells), it is clearly highly significant Because no sequence of individual points lay outside the control limits established above, we suspect that there is another, unknown source of error that scales with the input power This, of course, could be the postulated 'fusion effect', but the magnitude of the effect is commensurate with the errors The only reliable way of checking this is to construct calorimeters that are free of major sources of errors, and in particular, do not have a sloping baseline We therefore also used both isothermal and steady state (heat flow) calorimeters which satisfy this criterion

We have also analysed in detail the slope of the output curve to look for momentary power pulses on timescales shorter than the interval between calibrated points If the Joule input remains constant then this slope should not vary Any sudden or momentary extra power input, q_c, would change the slope by approximately $(k_{sb}+k_{c,0})q_c/M_0$ (M_0 is the water equivalent of the calorimeter, other symbols defined in Fig 2 legend) The number of significant deviations from the mean slope was found to be roughly the same for both the H_2O and the D_2O cells For the whole data set, the largest power excursion for a D_2O cell (6-mm

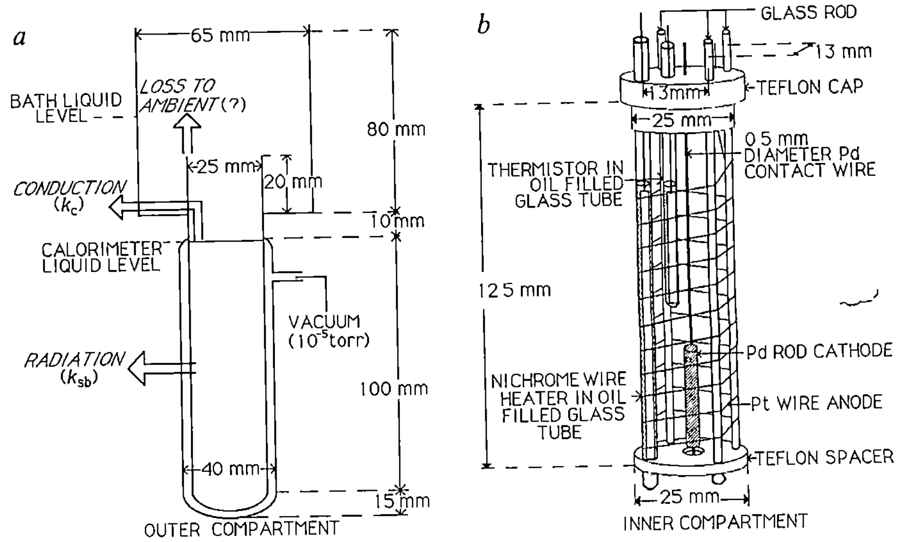

FIG 1 Schematic diagram of the FPH-type heat-flow calorimeter used here Heat flow paths are indicated here and discussed further in Fig 2 legend

METHODS As well as the Fleischmann, Pons and Hawkins (FPH) type, we used[10] two other calorimeter types—an improved heat-flow calorimeter (IHF) and an isothermal calorimeter The IHF calorimeters differed from the FPH type in three important ways First, they were larger a 500-ml-capacity cylindrical vessel constituted the cell, with anode-cathode spacing ~2 cm Second, the electrolysis vessel was inserted, using a film of oil for thermal contact, into a tightly fitting aluminium can which was itself packed around with insulating material and placed in a Dewar flask Whereas the temperature of the cell contents in the FPH calorimeter was determined using a glass-clad thermistor immersed in the cell itself, in the IHF design the temperature of the aluminium can was measured the can defined an isothermal surface for conduction of heat away from the cell and its use as the temperature measurement surface eliminated the sloping-baseline problem of the FPH design Third, the space within the Dewar flask above the electrolysis vessel was filled with a polystyrene cap extending well above the Dewar flask, with the aim of significantly reducing unquantified heat losses to the atmosphere The two types of heat-flow calorimeter were operated in water baths held at a constant temperature of 20 °C (±0 08 °C) The tops of the water baths were covered with a polystyrene lid In both cases the cells comprised a spirally wound Pt wire anode (0 25 mm) and a central Pd cathode (Johnson Matthey) For the FPH cells we prepared the different electrolytes using either conductivity water (H_2O cells) or slightly tritiated D_2O (specific activity 13 kBq ml^{-1}) of isotopic purity initially >99 9% We used 0 1M LiOD (D_2O from Aldrich, measured >99 9% initial isotopic purity) as the electrolyte in the IHF calorimeters The Pt and Pd contact wire was shrouded in glass tubing in the IHF cells to prevent any possible catalytic recombination of the electrolysis products In later experiments with the FPH cells we also used screened electrode contacts, but this had no effect on the results obtained The IHF cells contained a Pd wire electrode insulated to the very tip, which was positioned about three-quarters of the way up the cell This was used to define the internal liquid level during filling, or refilling, of the cell The larger volume of electrolyte in the IHF cells (300 ml) meant that refilling was required only occasionally, but the large thermal mass meant that the response was slow (time constant ~12 h) thus they were not sensitive to small bursts of heat We calibrated the heat-flow calorimeters using a nichrome wire heater placed in an oil-filled glass tube which was in contact with the cell contents The calibration procedure involved operating the heater, either without electrolytic current, or with a current significantly less (0 2–0 4 times) than the normal electrolysis current, until a steady-state temperature was attained With the FPH cells, use of a lower electrolysis current ensured continued stirring while diminishing the errors arising from the baseline drift, before each individual calibration the cells were refilled An empirical calibration curve was thus obtained by fitting the observed thermistor resistance, *R*, to a range of applied powers, *P*, using the equation $P=a-b(\log R)+c(\log R)^2$, where *a*, *b* and *c* are the fitted parameters The standard error of estimate on the fitted curve varied from 10 to as much as 70 mW with the FPH cells, largely reflecting the error in extrapolation to the reference level Neutron counting was performed in conjunction with the operation of the FPH cells, using two independent banks of counters mounted above the cells, on top of the water-bath cover[10] Detection sensitivity above background was 3 event s^{-1} in the cell We never observed a signal above background The isothermal calorimeter (J A Mason, R W Wilde, J C Vickery, B W Hooton and G M Wells, Proc 29th A Meet Inst Nuclear Materials Management, Las Vegas, Nevada, June 1988) comprises three concentric aluminium cylinders each separated by a heat transfer medium with a relatively low thermal conductivity The cylinder temperatures are maintained by electrical heaters wound as helical coils around each cylinder Temperature control is achieved by resistance thermometers on each cylinder which are used in conjunction with classical control software and the cylinder heaters The rate of thermal energy evolution in the measurement chamber (12 5-cm diameter, 26 cm high) is determined by measuring precisely the electrical power supplied to the chamber We operated the calorimeter at a measurement-chamber temperature of 42 ± 0 001 °C The measurement-chamber power resolution is <5 mW for an operating power of 20 W The electrolytic cell contained ~1 l of 0 1M LiOD The cathode was contained in a perforated glass canopy to prevent the evolved gases from mixing inside the measurement chamber The anode was a Pt foil cylinder 3 cm high and 12 cm in diameter surrounding the cathode The cell was thermally coupled to the calorimeter measurement chamber by conducting oil Measurements using Pt cathodes and also using nichrome wire heaters showed that there was a small systematic error in the calorimeter, an apparent power excess that varied linearly with the input power up to 100 mW for an input of 15 W A linear fit to these measurements (12 points, standard error of estimate 8 8 mW) was therefore used to apply a correction to the apparent excess measured for the Pd cathodes The measured output power of both the isothermal and IHF cells was corrected for the power loss that is due to evaporation of the electrolyte, assuming that the electrolysis gases were saturated in water vapour as they passed out of the cell (25 0 mW A^{-1} at 42 °C) $q_v=(p_v/p_0)(1\ 5)\Delta H_v I/(2F)$ where q_v is the power loss, p_v denotes the saturation vapour pressure and ΔH_v the latent heat of evaporation of the electrolyte, p_0 is the atmospheric pressure *F* is the Faraday constant and *I* is the current (assumes ideal gases)

---

[a] Johnson Matthey (JM) 'Specpure', drawn from sintered stock prepared from high-purity powder.

[b] D_2O from Harwell reference stock, contains 13 kBq ml^{-1} tritium.

[c] Mean Joule input power supplied to cell (see Fig. 2 legend). Values for IHF and isothermal calorimeters have been corrected for heat loss that is due to evaporation (see Fig. 1 legend).

[d] Excess power = measured cell output power − calculated Joule input power.

[e] (Mean ± 1σ) of values calculated after each refilling to the reference level, excluding first 10,000 minutes of polarization (see text).

[f] Mean and standard deviation of the mean calculated for all H_2O data points and all D_2O data points.

[g] Specially produced material supplied by JM—prepared from cast Pd stock that was argon-arc melted into rod form using a gravity casting process. The rods were subsequently sliced and bent to decrease the loading time required (maximum distance from bulk to surface ~1 mm). The sample was cleaned using acetone, 10% HCl and distilled water.

[h] 'Specpure' Pd arc melted three times under argon on a water-cooled copper hearth.

[i] A variety of ribbons prepared (JM) by melt spinning of cast or sintered Pd. A proportion of the ribbons were heat treated (JM) for 20 min at 100 °C under 10% H_2/N_2. Ribbon thickness, 125 μm.

[j] Type [a] that was subsequently vacuum degassed at 1,200 °C, and loaded with deuterium at a pressure of 40 bar. The sample was cooled to liquid-nitrogen temperature before transferring to the calorimeter to minimize loss of D_2.

[k] Sintered high-purity bar, sliced and bent to decrease the loading time required (maximum distance from surface to bulk ~1 mm).

[l] D_2O from Aldrich Chemical Co., contains ~15 kBq ml^{-1} tritium.

[m] Mean and standard deviation of all data points after temperature stabilization; data point every 3 min.

[n] Standard deviation given by $\sigma=\sqrt{\sigma_b^2+\sigma_y^2+\sigma_c^2}$ where σ_b is the standard deviation of the baseline measurement, σ_y that of the power measurement with the cell running and σ_c is the standard error of estimate of the correction line (see Fig. 1 legend). σ_b and σ_y were typically 6 mW, σ_c was 8.8 mW.

[o] Small error in this particular measurement gave rise to the apparent small endotherm.

rod) was ~45 mW and for an H_2O cell (6-mm rod) ~40 mW These are small compared with the input power It is certainly clear that no unusually large power pulses occurred Given the difficulties in operating these calorimeters, very occasional occurrences of small fluctuations cannot be considered as support for a 'fusion' hypothesis

The other two types of calorimeters used in this study are described in Fig 1 legend and results are given in Table 1*b* We explored a range of different preparations of palladium and of current density, up to nearly 600 mA cm^{-2} With the improved heat-flow calorimeters (IHF), the sign and magnitude of the power excess varied with Joule input power, but was always <5% Expressed in terms of the volume of the palladium cathode, this sets a limit of 100–500 mW cm^{-3} The most accurate calorimeter used was the isothermal calorimeter (minimum-detectable power change ~10 mW, minimum-detectable energy in any brief burst ~40 J) We analysed these results at four-hour intervals by averaging both the Joule input power and the measured output power over a period of ~20 min Inspection of the data collected every four minutes between the regions of analysis showed no obvious signs of any short heat 'bursts' and we found no trend with time of the measured output power under any of the conditions used Table 1*b* shows that we obtained thermal balance to better than 20 mW (24–240 mW cm^{-3} Pd) We observed slight thermal excesses (30–60 mW) during the initial charging period of the palladium beads, and during runs with high-surface-area cathodes at high current it can reasonably be assumed that a small amount of recombination (4% at most) was responsible for this effect

Neutron counting

We investigated the emission of neutrons from a wide range of cells using three different detector systems (Table 2) The large, high-efficiency detector with which most of the neutron measurements were made is an oil-moderated assembly of 56 $^{10}BF_3$ proportional counters configured as 5 concentric rings[11,12] The total efficiency for 2 45-MeV d–d neutrons is 44% We built an automatic cell shuttle mechanism to exchange regularly two nominally identical cells, only one of which was powered This enabled the background (which is due mostly to cosmic rays, there being no anti-coincidence counter arrangements) and any signal to be counted virtually simultaneously In operation the cells were exchanged every 5 min, and the data from the 5 rings were recorded separately Data from a typical run are shown in Fig 3 as differences in the count rate between the powered and unpowered cell Although in the particular example shown, two spikes can be seen in the count rate differences from the detector as a whole, it is clear that these spikes are due entirely to the misbehaviour of ring 4, and are therefore spurious

The details of the cells and results of the measurements are given in Table 2 The lowest limits (2σ) on neutron emission derivable from Table 2 for palladium are $1\ 5\times10^{-2}$ n s^{-1} g^{-1} or $1\ 5\times10^{-2}$ n s^{-1} cm^{-2}, if the emission were sustained over the whole run For titanium, the values are 3×10^{-3} n s^{-1} g^{-1} and 4×10^{-3} n s^{-1} cm^{-2}, although the latter limit is too high because it does not apply to the runs using granules having a large and indeterminate surface area If we assume the emission to be sustained over only a one-hour period at most, then the limits are, for palladium 7×10^{-2} n s^{-1} g^{-1} or 4×10^{-2} n s^{-1} cm^{-2}, and for titanium 8×10^{-3} n s^{-1} g^{-1} or 2×10^{-2} n s^{-1} cm^{-2} (much less in the runs with granules) The neutron-emission rate limits are several orders of magnitude below the rates of ~10^4 s^{-1} reported in ref 1 and about one order of magnitude below the rate of ~0 4 s^{-1} reported in ref 2 It is significant that the limits in our work were also obtained for cells in which cold fusion could be expected to be enhanced, in particular by using titanium cathodes in the form of a large (40 g) mass of porous granules to increase both the reaction volume and the surface area, and an electrolyte specifically chosen to promote deuterium loading into the cathode[13] (see Fig 3) As discussed later, we have not expressed the results in terms of the number of deuterium pai within metal lattices

Because the net count rates given in Table 2 are differenc between much larger background rates, runs were undertak with a calibrated ^{252}Cf source (0 024 ± 0 003 fissions s^{-1}) emitti 0 09 ± 0 01 n s^{-1} and a physically identical blank The result wa 0 14 ± 0 05 n s^{-1}, in satisfactory agreement Furthermore, th expected neutron output of the unpowered UPt_3 cell, which due to spontaneous fission of ^{238}U, was 0 22 s^{-1} The valu measured in comparison with an empty cell was 0 20 ± 0 06 s Our confidence in the results of the shuttle differences seem justified Measurements on $CeAl_2$ and UPt_3 cells were include in the hope that high effective electron masses correspondin to these metal crystal lattices would mimic in some way th fusion enhancement effect of 'heavy electrons' such as muo in binding the deuterium nuclei closer together The palladiu ribbon run with the cell power switched on and off every tw hours (which was about eight times the characteristic diffusio time in the ribbon) was undertaken to enhance the appearan of non-equilibrium effects, and results (negative) are given Fig 4

γ-ray counting

As it has been shown that cold proton–deuteron (p–d) fusio is expected to proceed at rates greater by ~8 5 orders of magn tude than d–d fusion[3], we carried out an alternative investigatio of electrolytic enhancement of hydrogen-isotope fusion by look ing for the D(p, γ)^{3}He 5,488-keV γ-rays from p–d fusion W used a lead-shielded 113-cm^3 n-type high-purity germ[illegible] (HPGe) crystal γ-ray spectrometer to search for any γ-[illegible] the energy range 0 1–7 MeV emitted by a variety of cold [illegible] cells operating with a mixture of light and heavy water [illegible]h results, also given in Table 2, are consistent with no γ-ra emission The lowest limits (2σ) on γ-emission derivable from Table 2 are, for palladium, 7×10^{-3} γ s^{-1} g^{-1} or 1× 10^{-3} γ s^{-1} cm^{-2}, and for titanium $1\ 4\times10^{-3}$ γ s^{-1} g^{-1} or 4× 10^{-4} γ s^{-1} cm^{-2}, if we assume that the emission is sustained ove the whole run Jones *et al*[2] report that the fusion activity ma last for only 4–8 h and begin ~1 h after the cell is powered, an in these circumstances typical values for the standard deviatio in the γ-ray emission rates are ~0 05 s^{-1} and the 2σ limits fo titanium are 4×10^{-3} γ s^{-1} g^{-1} or 3×10^{-3} γ s^{-1} cm^{-2} Post-ru analysis of the hydrogen isotopes taken up by the palladiu cathodes with the mixed light and heavy-water electrolytes use gave very satisfactory D H ratios, lying in the range 1 5–2 5 We note that if the proposed enhancement of the fusion proces is as valid for p–d as for d–d fusion then, because of the enhanc[illegible] tunnelling in the lighter d–p system[3], the γ-ray measurement actually provide a much more stringent limit on the cold fusio process than do the neutron measurements The interpretatio of the results from some of these cells was complicated by th dissolution of gold anodes and the consequent gold depositio onto the cathode this also would have affected the origina work[2]

Tritium enrichment

Fleischmann *et al*[1] claimed a tritium production rate o ~10^4 atom s^{-1}, commensurate with their reported neutro emission rate They used a differential technique in which th tritium accumulation in a cell with a palladium cathode wa compared with that in a cell with a platinum cathode They too samples for analysis at regular intervals and maintained a constant total electrolyte volume by the addition of fresh D_2O

Electrolytic enrichment is widely used to increase the concentration of tritium in water before analysis[14] Reproducibl results require careful control of the electrolysis, as the enrichment factor can vary widely (refs 15, 16 and R L Otlet, persona communication) important effects are seen with change o electrode materials, with variation in the condition (activity) o the electrode surface, with the current density (overvoltage) an with the temperature Without precautions, the variations in enrichment factor can be more than a factor of two[16] The claims therefore need to be assessed against this known variable electrolytic enrichment Surprisingly, Fleischmann *et al*[1] claimed that there was no electrolytic enrichment in their platinum cell

If the rates of electrolytic evolution of hydrogen isotopes are written as follows

$$D_2O \rightarrow D_2 + \tfrac{1}{2}O_2 \qquad \text{rate} = r$$

$$DTO \rightarrow DT + \tfrac{1}{2}O_2 \qquad \text{rate} = XSr$$

where r denotes the electrolysis rate, S the tritium-deuterium separation factor and X the mole fraction of tritium, T, in the solution, then the tritium accumulation is given by[10]

$$\frac{X}{X_0} = \frac{1}{(S+\alpha+\gamma)}\left\{1+\alpha+\gamma-(1-S)\exp\left[-\frac{(S+\alpha+\gamma)rt}{N_0}\right]\right\} \qquad (1)$$

where the total solution volume is maintained constant by the addition of fresh D_2O (containing a mole fraction X_0 of tritium, directly proportional to the disintegration rate), the ratio of the sampling rate of the solution to the electrolysis rate is α and γ denotes the ratio of the rate of evaporation of the solution to the electrolysis rate—a small correction that may be calculated assuming that the electrolysis gases passing out of the cell are saturated with water vapour On the timescales of interest, variability in S would give a variable enrichment

$$\delta\left(\frac{X}{X_0}\right) = -\frac{rt}{N_0}\,\delta S \qquad (2)$$

If the solution becomes contaminated by hydrogen absorption from the atmosphere, then if S_{obs} denotes the apparent DT enrichment factor derived from the application of equation (1), $S_{obs} = S/[0\ 5(1+f)]$, where $f = (1-X_H)/(1+X_H(S_{HD}-1))$ with X_H denoting the mole fraction of hydrogen and S_{HD} the HD separation factor (relative rate of reaction of HDO and D_2O) Therefore, as well as the inherent variability from one electrode to another, it is evident that any variability in the amount of hydrogen pickup will give a variation in the apparent enrichment factor

$$\frac{dS_{obs}}{dX_H} = \frac{S_{HD}}{2[1+X_H(S_{HD}-1)^2]}$$

We found that, unless exceptional precautions were taken (and we believe that we used experimental procedures very similar to those used in ref 1 (M Fleischmann, personal communication)), values of $X_H \approx 0\ 07$ were common Under these conditions, a change of X_H of only 0 01 would give a change in S_{obs} of 0 02, which could be significant given the smallness of the claimed effect.

Any assessment of whether differential enrichment can be considered to account for the results in ref 1 depends critically on the value of X_0, which was not reported Using values[1] of r ($1\ 24\times10^{18}$ atom s^{-1}) and N_0 ($14\ 6\times10^{23}$ atom) we calculate from equation (2) that if X_0 were at the extreme low end of the range for commercial D_2O (3 Bq ml^{-1}), a value of $\delta S = 0\ 46$ would be required, if it were moderate (10-15 Bq ml^{-1}) a value $\delta S \approx 0\ 1$ would be needed, if it were high (80 Bq ml^{-1}) $\delta S \approx 0\ 02$ would suffice

The applicability of equation (1) was confirmed experimentally, on both platinum and palladium cathodes, in conjunction with calorimetric and neutron-counting experiments (see Fig 5 legend) using D_2O with an initial tritium content of 13 kBq ml^{-1} (efficiency corrected) The fit of this equation to all the experimental data (Fig 5) gave, for palladium, $S_{obs} = 0\ 59$, and for platinum, $S_{obs} = 0\ 61$ Correction for the uptake of hydrogen, using $S_{HD} = 6$ (ref 16), gave $S \approx 0\ 48$, in agreement with previous work and theoretical expectations ($S = 0\ 46 \pm 0\ 02$, (refs 14, 15 and D S Rawson and R L Otlet, personal communication)) For individual electrodes, S_{obs} for palladium varied from 0 46 to 0 65 (corrected S from 0 42 to 0 58), whereas S_{obs} for platinum varied from 0 56 to 0 85 (corrected S from 0 43 to 0 69)—a total range for individual electrodes of $\delta S_{obs} = 0$ which is enough to account for the results of Fleischmann *et al*

It is clear from these results and discussion that more evidence needs to be presented before the tritium accumulation reported can be considered as experimentally reliable evidence for the occurrence of a fusion process

Materials characterization

With 125-μm palladium foils, hydrogen loadings (determined[1] by hot-extraction mass spectrometry of specimens frozen in liquid nitrogen, and independently by electrochemical extraction) of H/Pd = 0 95±0 05 were achieved in ~1 h a 100 mA cm^{-2} in 0 1 M LiOH solution with a platinum anode The limit of deuterium loading in 0 1 M LiOD was lower (0 84± 0 03) Rods (1- and 2-mm diameter) polarized for extended periods in neutron counting and calorimetry experiments showed D/Pd = 0 76±0 06 It is well known[17] that the equilibrium pressure for a given deuterium loading is higher than tha for the same hydrogen loading Current-interruption method confirmed that overpotentials in the range 0 8-1 V (ref 1) were being obtained From an initial composition >99 9% D_2O, the solutions degraded to ~98 5% in 24 h and to 88-98% (analysi by infrared spectrometry) following electrolysis for many weeks The resulting ratio H/D in the palladium was 0 02-0 04

During electrolysis, all of the palladium cathodes becar covered with a layer that varied in appearance from [illegible] tarnish to a dense jet black In the latter case, loose black materi was also formed, which in extreme cases came off during electrolysis, resulting in quite heavy erosion of the cathode The layer itself evidently represented a modification of the morphology of the cathode at the surface The formation of a thick black layer was enhanced at high current density, at high temperature, on smaller diameter wire and by frequent abrup alterations of the current density repeated over a long period The layer was more noticeable on the outside of a spiral-woun cathode than on the inside The layer was also more noticeabl on cathodes polarized in D_2O than on those polarized in H_2O (perhaps this is related to the greater equilibrium gas pressure for equivalent composition in the Pd-D system), and was different in appearance on materials from different sources These observations may be explained by the old idea[17] tha microfissures, or rifts, develop in palladium to release the mechanical strains resulting from the heavy loading of hydrogen together with the assumption that any such effect would dep on the stress state of the metal surface and its microstructure

Lithium was present in the surface layer on cathodes used in LiOD, and analysis by secondary-ion mass spectrometry (SIMS) apparently showed a concentration profile extending about 1 μm into the metal SIMS images showed that the lithium was not uniformly distributed, however, and it seemed likely that it was trapped in microfissures in the surface layer

Surface analysis showed a number of other species on and in the surface layer, notably small quantities of platinum and traces of copper, zinc, iron, lead and silicon platinum would have originated from the anode and silicon from the glass container No doubt the majority of the other contamination would have come from the solution the levels found (a few atom per cent, confined to the surface layers) were consistent with deposition by extended electrolysis from a solution o concentration around 10^{-9}-10^{-10}M One possible criticism is that low levels of such deposition could poison any essentia catalytic activity we therefore used pre-electrolysis in several experiments, in an attempt to lower the surface contamination We either made repeat experiments on the same solution, simply changing the cathode, or treated the solution beforehand in a separate cell

Because of claims that an unusual mechanism might lead t

TABLE 2 Measured neutron and γ ray emission rates for cold fusion electrolytic cells

a) Neutron emission rates

	Cathode				Details of electrolysis

[l] Melt spun ribbon provided by Johnson-Matthey Technology Centre

[m] Arc remelted twice electrolytically charged for 1 month in 0 1M LiOD then frozen in liquid nitrogen dipped in concentrated Na_2S solution and transferred to n counting cell

[n] Four 1-2-mm-thick discs of different types of Pd (Johnson-Matthey) spot welded to Pd wires plus strained Pd Wire

[o] Electrolyte reused after a previous run with a Ti cathode and Pt anode

[p] Material heated to 900 °C then quenched in water before use

[q] AuCN in Jones electrolyte replaced with $NaAuCl_4$

[r] Current on for 36 h then changed between 200 mA and 20 mA every hour

[s] Current on for 36 h then changed between 300 mA and 30 mA every 5 min

[t] Current changed slowly over range shown during electrolysis period as anode disintegrated

[u] Current on for 36 h then cycled off for 10 h and on for 2 h for period of 270 h Then 5 000 s at 380 mA cathodic and 4 000 s at 10 mA anodic for rest of period

[v] Current cycled on/off every 2 h Neutron yield is for on cycle

[w] The errors assigned (1σ calculated over full run duration) vary somewhat because in an attempt (mostly in the earlier stages of the programme) to cover as wide a range of cell configurations as possible pairs of unpowered + unpowered and powered + unpowered runs were not always carried out and consequently allowance has to made for slight differences in overall cosmic ray neutron detection efficiencies caused by slight differences between the two nominally identical cells

[x] These data were obtained using a different data acquisition system to drive the shuttle and accumulate data set up to look for neutron bursts[10]

[y] Cells exchanged every 5 min by hand

[z] All electrolytes used for γ ray work were 50 50 H_2O D_2O except * which were 41 59 H_2O D_2O

[aa] For the present measurements the system was calibrated with a set of standard γ ray sources and a $^{238}Pu/^{13}C$ (α nγ) source emitting 6 129 keV γ rays The cells were positioned such that their cathodes were as close as possible to the detector crystal and the detection efficiencies were calculated by integrating previously measured[21] point efficiency functions over the cathode volume Peaks were searched for at 5 488 4 977 and 4 466 keV corresponding to the expected location of the full energy single escape and double escape peaks using the method recommended in ref 22

nuclear reactions proceeding predominantly non-radiatively to ^4He, four cathodes (Table 2, first four entries) were analysed by vacuum fusion/mass spectrometry. The high vapour pressure of palladium at the melting point caused difficulties, so internal standards were prepared by ion implantation of 10^{13} and 10^{15} atoms of ^4He into samples cut from the cathodes. Detection limits for ^3He and ^4He determined in this way were $\sim 8 \times 10^{10}$ atoms per sample—$(1\text{–}10) \times 10^{11}$ atom g^{-1}. We found no ^3He or ^4He. The expected level, if fusion had been occurring at the rate reported in ref. 1, was $\sim 10^{16}$ atom g^{-1}.

Evolution of hydrogen at a titanium cathode resulted, as is well known[13], in a dense network of hydride precipitates, observable by standard metallographic methods, penetrating below the surface. In 0.1M D_2SO_4 electrolyte at 100 mA cm^{-2}, the network penetrated ~30 μm in 1 h. Precious-metal deposition inhibited the electrolytic uptake, presumably by lowering the overvoltage and promoting gas evolution. Electrolysis in the 'brew' used by Jones *et al.*[2] resulted in hydride precipitates confined to the grain boundaries; other experiments showed that the presence of $PdCl_2$ in the electrolyte caused this effect, presumably as a consequence of palladium plating on the cathode. It is clear that expressions of the fusion rate that assume that the cathode has composition TiD_2 are completely misleading: metallography shows that the number of deuterium pairs is far fewer, hence the claimed fusion rate per deuterium pair is far higher than the figure given, and so the results are even more difficult to reconcile with expectations than had been implied[2].

Discussion

The interest in cold fusion has generated a large number o neutron counting experiments. It is well known that, in genera it is inadvisable to measure the signal + background and bac ground of counting measurements at different times and i different physical locations (as in ref. 1), because of unexpecte systematic variations. This is especially true for low-count-rat experiments. Compensating for variation of the background rat and assessing appropriate errors for the procedure chosen ar particular problems. The work of Jones *et al.*[2] can be criticize for such errors[18]. It is notable that in ref. 2, only one run i fourteen showed a significant effect and then only because th particular run was assigned a smaller counting error than th others. Here we have attempted to minimize, by the shuttl procedure, uncertainty about background and counter variabil ity and about error calculation. Given some of the more spec tacular claims that have been made, we note that further cautio is advisable because of the notorious sensitivity of $^{10}BF_3$ an ^3He proportional counters to humidity and of counter-amplifie systems to earth loops. In our work the neutron detectors wer segmented, and the relationship between signals from the seg ments was well known, so spurious effects giving inconsisten signals from the segments could be identified.

Failure to reproduce the effects has been attributed by som to the need for rigorous exclusion of hydrogen and claims hav been made that palladium electrodes must be cast and carefull degassed before use, to remove all traces of carbon and hydroge impurity which might decorate dislocations or other high-energ

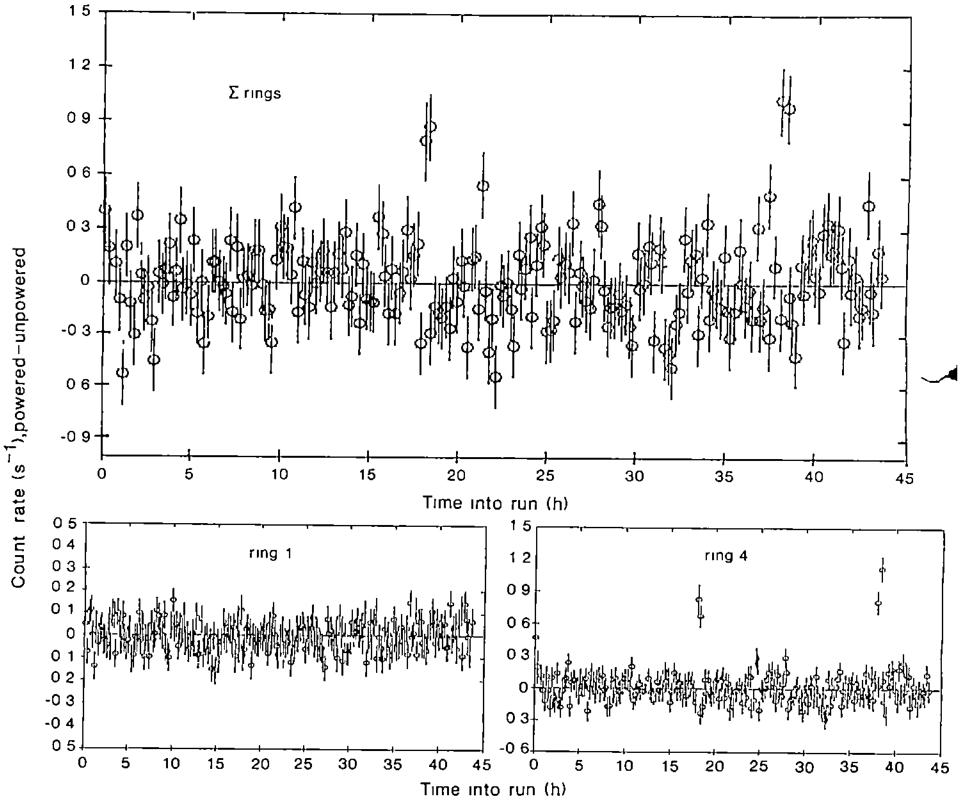

FIG. 3 Data from a typical run on the large high-efficiency neutron detector. These show the differences between count rates for powered and unpowered cells resulting from successive alternate shuttle positions for 40 g of titanium granules in 0.1M D_2SO_4. The errors shown are 1σ errors for each five-minute counting period. In addition to results from the detector as a whole, results from two of the five rings of 2-inch diameter 107-cm active length $^{10}BF_3$ proportional counters are also shown. The counts in rings 2, 3 and 5 (not shown) were very similar to those in ring 1. The apparent bursts were seen only in ring 4 and are therefore a spurious effect. A tube (90-mm inner diameter) passes through the centre of the detector, and the shielding consists of 6 inches of borated resin, 1 mm of cadmium and 2 inches of lead. The neutron detection efficiency is high and is largely independent of neutron energy, varying from 48% for 0.5-MeV (Am/Li) neutrons to 40% for 4.2-MeV (Am/Be) neutrons. The background count rate is 4-5 count s^{-1}, mostly neutrons from cosmic rays. Each of the five rings of counters has its own independent pre-amplifier, pulse-shaping amplifier and discriminator, and the mean energy of neutrons counted can be obtained from the ratio of counts in the outermost ring of counters (ring 5) to counts in the innermost (ring 1). Because neutron counts are distributed over five rings, and because of the 135-μs-mean time to capture, neutrons emitted simultaneously from a source as a burst are counted separately (as seen with the ^{252}Cf source, for example). The pre-amplifiers, high voltage components and insulators are all contained within a desiccated electrically screened box, and we eliminate earth loops and induced electromagnetic pick-up ('aerial') effects from external coaxial-cable runs to the PDP-11/45 data-acquisition computer by using isolating high-frequency pulse transformers and by winding the coaxial cables many times around ferrite rings. The neutron detector and its immediately associated electronics are located in a temperature-controlled air-conditioned blockhouse with two-foot-thick concrete walls and roof.

ites (ref 19 and R. A. Huggins, Workshop on Cold Fusion, anta Fe, May 1989): this is however inconsistent with the ostulate of a 'fusion' origin for the effect because, at low nergies, p-d fusion is expected to be significantly faster than -d fusion[3]. Furthermore, the original reports[1,2] did not mention ny special precautions to exclude atmospheric water vapour part from careful covering of the electrolytic cells. We followed imilar procedures, and found that degradation of the heavy ater by exchange with atmospheric moisture occurred quite apidly. Alternatively, it is claimed that it is essential to maintain high current density for a considerable period (A. J. Appleby, Vorkshop on Cold Fusion, Santa Fe, May 1989) although it is ot completely clear whether these latter claims are in fact eproductions of the effect reported in ref. 1 or are something ifferent. In our neutron counting experiments, fresh dislocaions were introduced by plastic deformation, some counting xperiments were carried out at current density as high as A cm^{-2} (Table 2) and in one experiment in the isothermal alorimeter a high current density was maintained for a considerble period (Table 1). Trace deposition of platinum on the athode, supposedly causing a lowering of the overpotential for euterium evolution and hence a lowering of the attainable euterium level in the cathode, has also been suggested as an xplanation for irreproducibility (M. Fleischmann, personal ommunication). We observed no effect when we used palladium nodes in our neutron counting experiments.

Timescales for hydrogen and deuterium loading consistent ith the expected diffusion time (x^2/D where the diffusion oefficient, $D = 10^{-7}$ cm^2 s^{-1} and x is the radius or half-thickness f the specimen) were measured[10] and nuclear counting and alorimetric experiments were always conducted over periods uch longer than this. Furthermore, in the process of electrolytic oading of palladium, there will clearly be a concentration radient, a moving phase boundary and the outer atomic layers f the metal will be saturated (possibly supersaturated) with euterium[17]. It might be expected, therefore, that sufficiently ensitive equipment would detect any fusion process well before e material is completely loaded. Because our neutron detection ensitivity was $\sim 10^5$–10^6 times greater than that of Fleischmann t al.[1], it seems unlikely that any greatly enhanced fusion process ssociated with the absorption of deuterium into palladium, iving rise to neutron emission, is occurring. We are, of course, ware that it is always possible to construct essentially untestable eories involving hypothetical special conditions of the metal r of its surface. Careful characterization of materials for which ositive results are claimed is therefore of great importance.

It has been argued that the neutron branch of the d-d reaction ight be completely suppressed in favour of the (t+p) branch nd it has been further argued (S. Pons, personal communicaon) that the tritium produced as a result of a nuclear process nside the electrode need not necessarily exchange with the lectrolyte and might not therefore be detected. However, the ther product of such a nuclear process, a high-energy proton, hould be detectable by its interaction with the lattice, includng neutron emission: we estimate, knowing the rate of energy ss of the protons and by comparison with (p, n) reaction ross-sections for neighbouring elements, a yield of $\sim 10^{-6}$ neutron per proton, implying a neutron yield in our ounting experiments of as much as 10^4 s^{-1} if fusion at the rate eported in ref. 1 were to proceed entirely through the (t+p) ranch.

In view of the rather large d-d separations in both PdD and iD_2, it might be argued that fusion requires some non-equilirium state in the lattice—perhaps at the α/β phase boundary n palladium or at the tips of the growing TiD_2 needles or at a attice defect—where the d-d or p-d separation could be greatly educed. Here we created non-equilibrium situations by pulsing he current but we detected no neutron emission (Fig. 4).

Some explanations of the apparent excess heat production ave emphasized recombination processes at catalytic metal surfaces[20]: apart from occasional explosions, however, which did not result in any detectable neutron emission, we found, by comparison of the volume of water added to maintain the cell volume with the electrolysis charge passed, that this was not a significant effect (in agreement with others[9]). Recombination in the gas space above the liquid, either on exposed cathode surface or catalysed by colloidal metal particles eroded from the cathode, might however account for some of the observations of bursts of heat recently reported (M. Fleischmann and S. Pons, Electrochemical Society Meeting, Los Angeles, May 1989). In discussing the claims in ref. 1, we prefer to focus on characteristics of the 'simple' Fleischman, Pons and Hawkins (FPH) calorimeters, because we have only observed small effects (at the level of the inherent uncertainties), which might mistakenly be claimed as arising from cold fusion, in the one type of calorimeter (FPH type) that has major calibration difficulties. Cells using the same electrode and electrolyte materials operated in calorimeters that did not have these problems exhibited none of these effects.

There are two points regarding the calibration that could have a profound effect on the apparent results obtained with FPH-type calorimeters: the first concerns when the calibration is performed and the second how it is performed. Concerning the first point, it seems from our work and that of Lewis *et al.*[8] that a calibration performed during the first 10,000 min of electrolysis could be seriously in error and lead to an erroneous conclusion that subsequently, rather than being in balance, the cells were exothermic. Concerning the second point, Fleischmann *et al.*[1] describe calibration using the internal-resistance heater, by measurement of Newton's-law-of-cooling losses. Typically, this procedure might involve the application of power to the heater while electrolysis was occurring, following the temperature-time trace until a steady state was obtained, then switching the heater off and following the cooling curve. This procedure gives an approximation to the differential calorimeter constant, $k_d = d(\Delta P)/d(\Delta T)$ (where P is power and T is temperature) at the operating temperature of the cell and can give rise to errors in two ways. First, because any calibration sequence would require

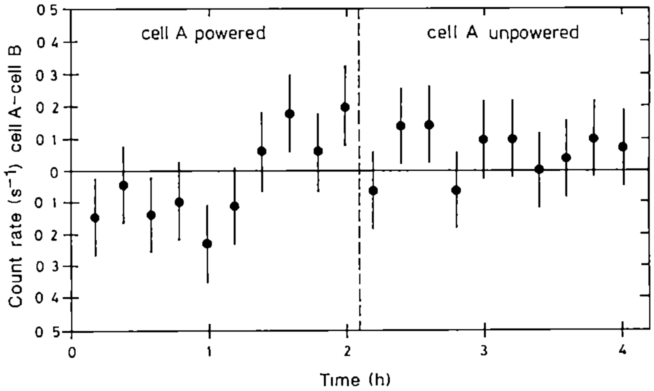

FIG. 4 Time dependence of neutron emission from an electrolytic cell with melt-spun Pd ribbon cathode and Pd foil anode, with power alternately turned on for deuterium loading and off for relaxation every 2 h by the data-acquisition computer: see Table 2 footnote *l*. The total length of the run was 110 h, and the sums of the 'on' and 'off' data are shown. After 90 h of running, we added 1 μM Pb^{2+} (to poison the surface by Pb deposition) to the solution. There was no difference between the data in the presence and absence of Pb^{2+}, and so data for the whole run was combined. This run was undertaken to enhance the appearance of the non-equilibrium effects discussed in the text. It is assumed that the ribbon would have had a high density of grain boundaries, dislocations and other lattice defects. Because the 'on' and 'off' periods were several times the characteristic diffusion time for the ribbon, it is assumed that the composition was cycling in the β-phase region between the fully loaded condition (D/Pd ≈ 0.83) and the limit of the (α + β) phase field (D/Pd ≈ 0.65).

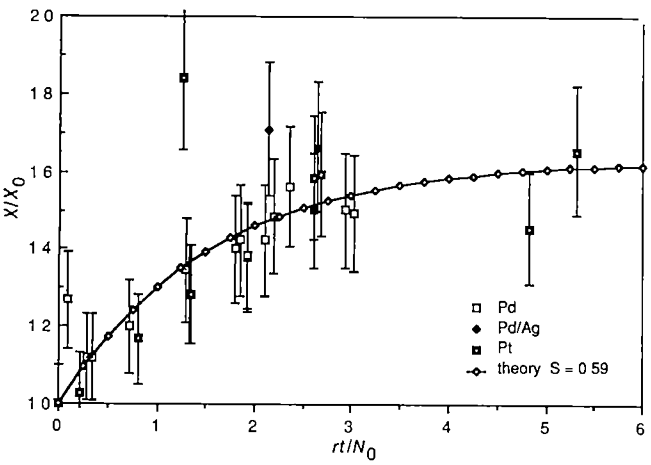

FIG. 5 Tritium enrichment by electrolysis in open cells at constant volum with both Pd and Pt cathodes: relative count rate X/X_0 against amount c electrolysis rt/N_0 (symbols defined in the text). Initial count rate (efficienc corrected) was 13.0±0.6 kBq ml^{-1}. Errors are 1σ. The Pd cells were th FPH calorimeters, sampled after 490-660 h, the cells in the first section c Table 2 (footnotes *a–e*) sampled at the end of the run and one cell fror the high-efficiency neutron detector—footnote *k* in Table 2. The line is th fit to equation (1).

5–10 h, extrapolation would be required to obtain the correct value at the reference liquid level: an estimated error of 20% or more could result. Furthermore, because the evaporation of the cell contents increases markedly with increasing temperature, the baseline slope would increase with increasing temperature and the effects of this sort of error would become correspondingly more marked: the claimed effects were indeed greatest in the cells run at the highest input power. Second, these calorimeters are nonlinear (equation (3), Fig. 2 legend), with the effect being significant when the temperature gradient is large: they cannot be described by a simple Newton's-law-of-cooling constant. If a differential calorimeter constant is used to derive the input power, the calculated output would be (from Fig. 2 legend, equation (3))

$$P_{\mathrm{app}} = k_{\mathrm{d}}\Delta T = (k_{\mathrm{sb},0} + k_{\mathrm{c}})\Delta T + 3(k_{\mathrm{sb},0}/T_0)(\Delta T)^2$$

so that, in comparison with the correct output (equation (3))

$$P_{\mathrm{app}} - P = 3k_{\mathrm{sb},0}(\Delta T)^2/2T_0)$$

If the power applied to the heater is significant compared with the electrolysis power then this error will be even greater. Back calculation from the data given in ref. 1 shows that the claime effects were largest for Joule input powers on the order of 6 W For our FPH-type calorimeters, this would have given $\Delta T \approx$ 50–60 °C. Therefore, had these cells been calibrated in this way an apparent heat excess on the order of 0.8–1 W would hav been observed. Our method of calibration (see Fig. 1 caption considerably reduced the effect of these sources of error. Th original report[1] was clearly preliminary in nature, and it i evident from the above that the claims made therein cannot b assessed in the absence of a detailed description of the experimental procedure used and of the methods used to compensat for the systematic errors inherent in the use of a simpl calorimeter.

We feel that our work has served to establish clear bound for the non-observance of cold fusion in electrolysis cells, unde carefully controlled and well understood experimental conditions and using well characterized materials. Further detail are given in ref. 10. Claims of observations of cold fusio ought now to meet similar standards of data analysis an materials characterization so that a proper assessment can b made. ☐

Induction of self-tolerance in mature peripheral B lymphocytes

Christopher C. Goodnow, Jeffrey Crosbie, Helle Jorgensen, Robert A. Brink & Antony Basten

entenary Institute of Cancer Medicine and Cell Biology, University of Sydney, New South Wales 2006, Australia

n transgenic mice, mature peripheral B lymphocytes in lymphoid follicles, like immature B cells, are rendered tolerant by encounter with self-antigen, provided receptor occupancy by self-antigen exceeds a critical threshold The tolerant state of the B cell is closely correlated with down-egulation of membrane IgM but not IgD antigen-eceptors Identical changes in antigen-receptor xpression occur in a subset of follicular B cells n nontransgenic mice, suggesting that clonally ilenced self-reactive cells are common in the eripheral B-cell repertoire

o maintain a state of immunological self-tolerance, potentially elf-reactive lymphocytes must be prevented from mounting nmune responses to autologous antigens In the case of T ymphocytes, irreversible clonal deletion of self-reactive cells as recently been shown to play an important role in maintaining elf-tolerance within the T-cell repertoire[1-5] Selective deletion f self-reactive T cells occurs within the thymus by a mechanism milar to that orginally proposed by Lederberg[6], whereby the nteraction between self-antigen and the T-cell receptor at an nmature stage in T-cell differentiation aborts any further evelopment of the cell[7] Such a censoring mechanism is ffective in maintaining self-tolerance within the peripheral T-ell repertoire because the sequence and specificity of T-cell eceptors remains constant after receptor gene rearrangement[8-10] Self-tolerance in B-lymphocytes, however, poses an dditional problem because the antigen-binding sites of nmunoglobulins are further diversified after B cells have left bone marrow, by hypermutation of immunoglobulin genes in mature, peripheral B cells[11,12] Hypermutation of nmunoglobulin genes not only provides the extra diversity eeded for production of high-affinity antibodies to most foreign ntigens[11,12], but also results in generation of self-reactive B-cell ariants at a detectable frequency[13,14] To prevent production f high-affinity pathogenic autoantibodies by this 'second wave' f self-reactive B cells, a mechanism of self-tolerance is required hat can act at multiple stages of B-cell development

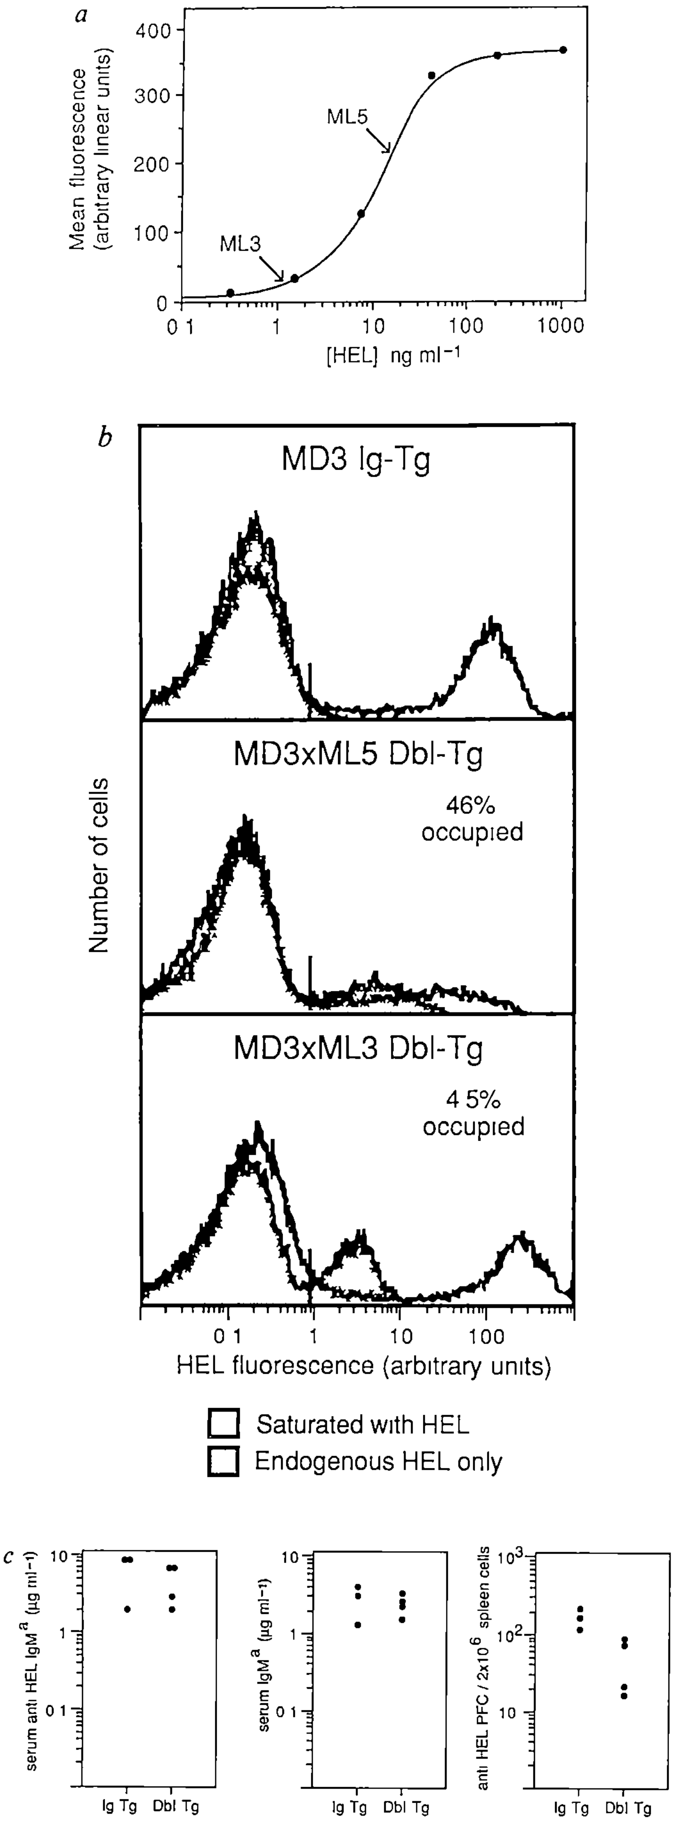
High-affinity antibody responses to xenogeneic or allogeneic roteins or cells have long been known to be restricted to pitopes that differ between immunogen and self, despite the resence of many cross-reactive epitopes on such antigens[15,16], nd this principle underlies the widespread practical use of pecies- or allele-specific antisera and monoclonal antibodies s T-cell 'help' is potentially available to any B cell capable of inding and presenting the immunogen[17], the restriction of the ntibody response to those epitopes on xeno- or alloantigens hat are not cross-reactive with self provides a clear indication hat self-reactive B cells are censored at some stage during the eneration of a high-affinity antibody response[16] Indeed, vidence for induction of tolerance at multiple stages of B-cell evelopment, including mature and memory B cells, has been epeatedly found in *in vivo* models of tolerance induction to exogenous antigens administered in an appropriate form[18-26] It has been difficult, however, to determine the fate of the unresponsive mature peripheral B cells in these models because of the low-frequency of antigen-specific B cells Also, the possibility remains that some examples of *in vivo* B-cell unresponsiveness may involve immunoregulatory mechanisms not directly related to self-tolerance, such as exhaustive differentiation into plasma cells, feedback effects due to antigen-antibody complexes and receptor blockade[20,21,26]

To increase the frequency of potentially self-reactive B cells, thereby allowing their fate to be traced *in vivo*, we have recently developed a transgenic mouse model in which hen-egg lysozyme transgenic mice were mated with anti-lysozyme immunoglobulin-transgenic mice to create 'double-transgenic' offspring[27] The anti-lysozyme B cells from these mice encountered lysozyme as a self antigen throughout their development within the bone marrow and in the periphery Despite this, the B cells were not deleted, but persisted in a functionally silenced state characterized by expression of high levels of membrane IgD but a 10-20 fold reduction in membrane IgM[27] The current paper describes the use of the same transgenic model to follow the fate of self-reactive B cells when they encounter self-antigen only at the mature stage of development, in peripheral lymphoid organs As observed previously in conventional *in vivo* models, mature follicular B cells in the transgenic mice were fully susceptible to induction of self-tolerance Also, the silenced state appeared identical to tolerance induced by encounter with self-antigen early in B-cell development, in that it required comparable levels of receptor occupancy, and was intimately linked to downregulation of membrane IgM but not IgD A significant proportion of IgD^+ follicular B cells in nontransgenic mice show an identical change in membrane IgM, indicating that clonally silenced self-reactive B cells may be frequent in peripheral lymphoid organs

Low-lysozyme double-transgenic mice

In previous experiments[27], functional silencing of anti-lysozyme B cells took place in double-transgenic mice derived from matings of two parental lines The first line, ML5, was the highest expressing of a series of transgenic lines bearing the hen-egg lysozyme (HEL) gene linked to the mouse metallothionein promoter The other parental line, MD3, was one of six lines bearing rearranged immunoglobulin heavy and light chain genes encoding high affinity anti-lysozyme IgM and IgD, the two isotypes being expressed by differential RNA-splicing from the V-μ-δ heavy chain transgene Lysozyme-binding B cells persisted in peripheral lymphoid organs of the resulting double-transgenic progeny, but they no longer secreted anti-lysozyme antibody and exhibited an altered phenotype, characterized by a 10-20 fold reduction in membrane IgM with no change in membrane IgD Developing B cells in the bone marrow of the double-transgenic mice encountered lysozyme shortly after expressing surface IgM, as bound lysozyme could be demonstrated on these cells (see below) and because down-regulation of membrane IgM was observed even on newly differentiated $B220^{low}$ bone marrow B cells (D Y Mason *et al*, manuscript in preparation)

In terms of B-cell receptor occupancy in the double-transgenic mice, the mean concentration of lysozyme in the serum of the



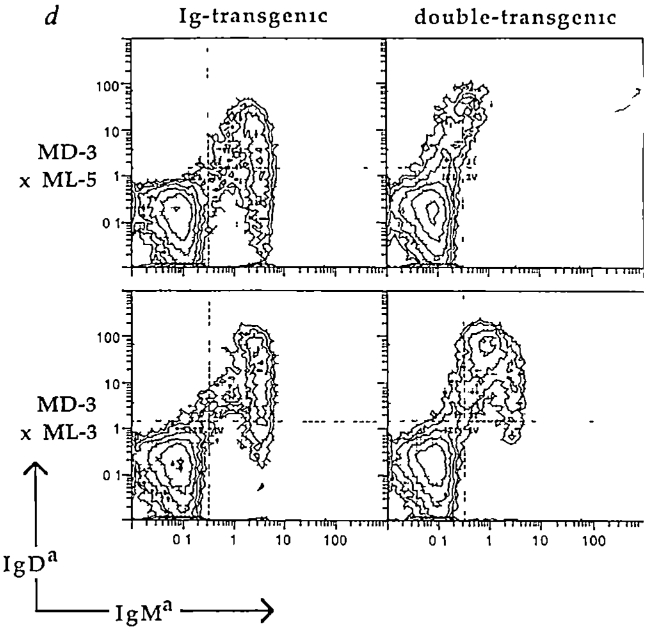


FIG 1 Lysozyme-binding B cells in ML3 × MD3 double-transgenic mice exhibit decreased antigen receptor occupancy (*a*, *b*), failure of B-cell silencing (*c*), and absence of IgM-downregulation (*d*) *a*, Binding of lysozyme to MD3 immunoglobulin-transgenic spleen cells *in vitro* titrated over a range of lysozyme concentrations, by measuring subsequent binding of a biotinylated second anti-lysozyme monoclonal antibody on the FACS *b*, Both immunoglobulin- and double-transgenic spleen cells exposed to saturating concentrations of lysozyme (unshaded histograms) or no lysozyme (shaded histograms) *in vitro* before second-step staining with the biotinylated anti-lysozyme monoclonal antibody Positively staining cells in the shaded histograms therefore reflect cells which have bound lysozyme *in vivo* before preparation and staining *in vitro* *c*, Spontaneous secretion of transgene-encoded (a-allotype) anti-lysozyme IgM measured in the serum of MD3 × ML3 double-transgenic mice and immunoglobulin-transgenic littermates by lysozyme-binding enzyme-linked immunosorbent assay (ELISA) (*c*, left panel) or by IgM^a allotype ELISA (*c*, centre), and by quantitating the number of anti-lysozyme IgM plaque-forming cells (PFC) in the spleen (*c*, right) Each point represents the value from an individual mouse *d*, Expression of transgene-encoded membrane IgM and IgD on spleen cells from MD3 × ML5 or MD3 × ML3 double-transgenic mice and immunoglobulin-transgenic littermates determined by two-colour FACS analysis Dots and contours are set respectively at 1 or more cells and 5, 10, 20, 40, 80, and 160 cells per 4 × 4 channel grid

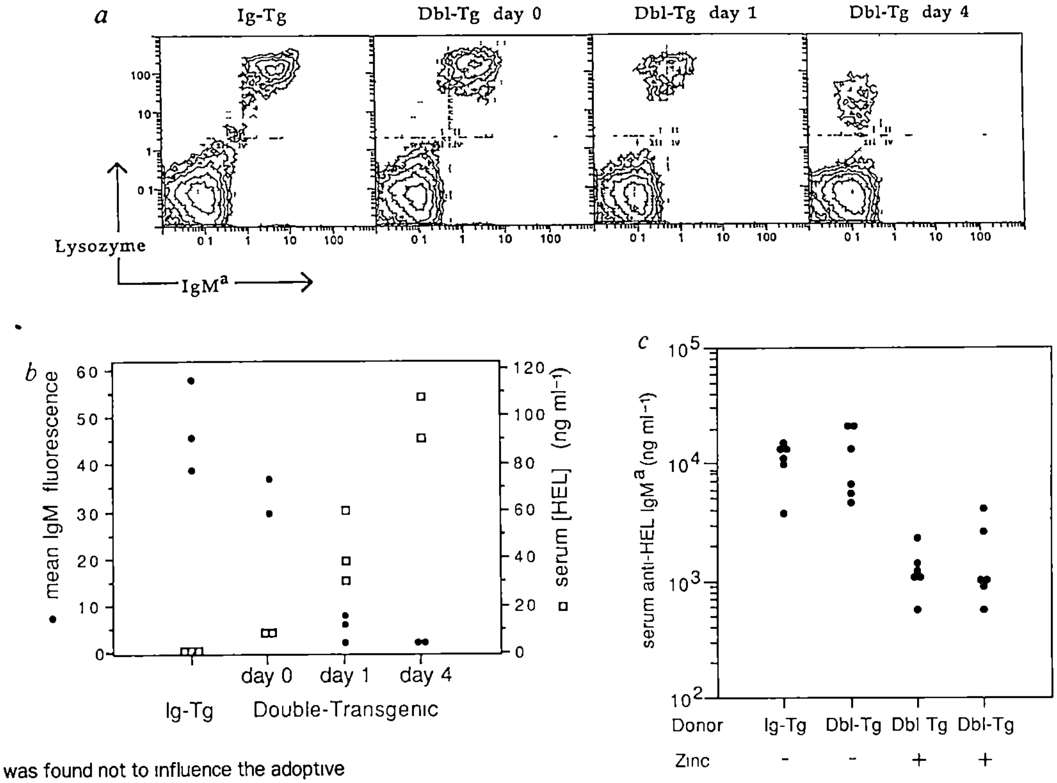
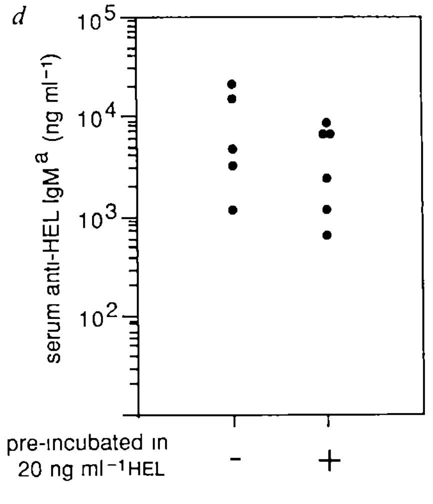
METHODS Transgenic mice were derived from C57BL/6 founders as described[27] and maintained by backcrossing to C57BL/6 Lysozyme-binding was measured by incubating spleen or bone marrow cells with either no HEL or the indicated concentrations of HEL on ice for 25 min, followed by staining with biotinylated HyHEL9 and streptavidin-phycoerythrin as described previously[27] Logarithmic amplifiers on the FACS were calibrated using a series of standards, and the resulting nomogram used to convert mean fluorescence channel number to mean linear fluorescence Per cent receptor occupancy was then derived by determining the mean fluorescence of the positively staining cells, using the gates shown, in the absence of any added HEL (shaded histograms), and dividing this value by the mean fluorescence of the same population of cells when all available receptors were saturated with 200 ng ml^{-1} HEL (unshaded histograms) Anti-lysozyme IgM^a was measured at several dilutions from sera by ELISA on HEL-coated 96 well plates as previously, except that the assay was developed with biotinylated anti-IgM^a monoclonal antibody RS3 1 (ref 51) followed by avidin-alkaline phosphatase (Sigma) Absolute concentrations were determined relative to a standard curve of culture supernatant from SP2/0 cells transfected with the anti-HEL immunoglobulin genes Measurement of serum IgM^a allotype, anti-HEL direct plaque-forming cells, and two-colour FACS analysis were all as described previously[27] arental ML5 mice (17 4 ng ml^{-1}), and in ML5×MD3 double-ansgenic progeny, was close to that required to half-saturate ie anti-lysozyme immunoglobulin receptors expressed by MD3 mmunoglobulin-transgenic B-cells *in vitro* (Fig 1*a*), and *in vivo* Fig 1*b*) Because the lysozyme concentration in ML5×MD3 ouble-transgenic mice lies in the steepest portion of the receptor tration curve (Fig 1*a*), a relatively small reduction in lysozyme xpression would be expected to result in a large decrease in eceptor occupancy *in vivo* To examine the effect of such a ecrease in receptor occupancy on B-cell silencing, the same ne of immunoglobulin-transgenic mice, MD3, was mated with different line of metallothionein-lysozyme transgenic mice, IL3, which expressed an order of magnitude less lysozyme mean serum HEL, 1 4 ng ml^{-1})

In ML3×MD3 double-transgenic mice, only 4 5% of anti-ysozyme membrane immunoglobulin on splenic B-cells was ccupied with lysozyme (Fig 1*b*), compared with 46% ccupancy in ML5×MD3 double-transgenics A similar ifference in receptor occupancy was found on bone marrow B ells (data not shown), indicating that in both types of double-transgenic mice, lysozyme was encountered early in B-cell differentiation Comparison of these low-lysozyme double-transgenics with immunoglobulin-transgenic littermates revealed that, in contrast to the profound silencing of anti-lysozyme B cells observed in ML5×MD3 double-transgenic mice[27], there was little or no reduction in the concentration of transgene-encoded anti-lysozyme IgM in the serum of ML3×MD3 double-transgenics, and the number of cells secreting anti-lysozyme IgM in the spleen was only slightly lower than that of immunoglobulin transgenic littermates (Fig 1*c*) In addition to the failure of tolerance in ML3×MD3 double-transgenic mice, FACS analysis of their spleen cells revealed minimal down-regulation of membrane IgM on the anti-lysozyme B cells (less than twofold), compared with the 10-to 20-fold reduction in surface IgM on silenced B cells from ML5×MD3 double transgenic mice (Fig 1*d*) Conversely, the T-helper cell compartment in ML3 transgenic mice was tolerant to lysozyme (S Adelstein, unpublished results, see below), which is consistent with previous data showing a lower antigen concentration threshold for induction of unresponsiveness in T cells[18]





G 2 Zinc-induction of serum sozyme in adult MD3×ML3 ouble-transgenic mice is accom-anied by rapid downregulation of embrane IgM and induction of lerance MD3×ML3 double-ansgenic mice or immuno-obulin-transgenic littermates ere given drinking water con-ining 25 mM zinc sulphate for r 0, 1 or 4 days All mice were lled at the same time *a*, ysozyme-binding versus IgM^a rofiles of spleen cells obtained y two-colour FACS analysis *b*, lean IgM levels on lysozyme-inding B cells expressed in rbitrary linear units compared to erum lysozyme concentration in dividual animals at each time oint *c*, Antibody responses of plenic B cells from individual nmunoglobulin-transgenic, unin-uced double-transgenic or 4-day duced double-transgenic mice leasured in adoptive transfer, e dots represent the concentra-of serum anti-HEL IgM^a in dividual recipients of spleen ells from two different zinc-nduced double-transgenic mice n other experiments, zinc exposure was found not to influence the adoptive esponse of immunoglobulin-transgenic spleen cells (data not shown) *d*, eceptors on MD3 immunoglobulin-transgenic spleen cells were artificially locked' by exposure to a half-saturating concentration of lysozyme 20 ng ml^{-1}) on ice for 1 h before adoptive transfer

IETHODS All transgenic mice were maintained on a C57BL/6 background, nd used at 8–14 weeks of age Serum HEL was measured by capture LISA[52] using 96-well plates coated with the monoclonal antibody HyHEL10 erum was tested at a dilution of 1 5 or 1 10, and bound HEL revealed with iotinylated monoclonal HyHEL9 followed by avidin-alkaline phosphatase bsolute values were derived from a standard curve of purified HEL FACS nalysis was performed as previously described, staining for HEL-binding ncluded a first step exposure to 200ng ml^{-1} HEL to saturate any remaining ree receptors Mean IgM^a on HEL-binding cells was measured by staining vith fluoresceinated RS3 1 antibody and conversion to mean linear fluorescence using a calibrated logarithmic amplifier as described in Fig 1 Adoptive ransfer was carried out as previously described[27], transgenic spleen cells 10^4) were injected intravenously together with 5×10^6 HRBC-primed 57BL/6 cells and 2×10^8 HEL-HRBC into 750 rad irradiated C57BL/6 ecipients Serum anti-HEL in the recipients was measured 7 days later as lescribed in Fig 1

Induction of lysozyme in adult mice

The findings in the low-lysozyme double-transgenic mice suggested that tolerance induction and the accompanying down-regulation in surface IgM depends on exposure of anti-lysozyme B cells to a threshold concentration of lysozyme which corresponds to a receptor occupancy of between 4 5% and 45% of surface immunoglobulin They do not indicate, however, whether such a tolerance threshold is unique to immature B cells[26], nor whether mature B cells would in fact be triggered rather than silenced if above-threshold concentrations of lysozyme were encountered only after nontolerant B cells had matured in adult animals To answer these questions, the serum lysozyme concentration in ML3 × MD3 double-transgenic mice was elevated above the putative threshold by exploiting the heavy metal inducibility of the metallothionein promoter[28] Adult ML3 × MD3 low-lysozyme double-transgenic mice were given drinking water containing 25 mM zinc for 0, 1 or 4 days As a result, the serum lysozyme concentration was elevated to 29-60 ng ml^{-1} in mice exposed to zinc for 1 day, and reached 89-108 ng ml^{-1} following exposure for 4 days (Fig 2*b*) In parallel with the rise in lysozyme concentration, membrane IgM on HEL-binding spleen cells from these mice was partially downregulated by day 1 (Figs 2*a*,*b*), and by day 4 of zinc exposure had fallen to a level comparable with that observed in the ML5 × MD3 double-transgenic mice Importantly, at the intermediate timepoint there was no evidence for a bimodal distribution of membrane IgM levels expressed by the B cells (Fig 2*a*) and at no stage was there a reduction in the number of B cells, excluding the possibility, therefore, that pre-existing $\mathrm{IgM}^{\mathrm{hi}}$ cells were simply being replaced by a discrete population of $\mathrm{IgM}^{\mathrm{low}}$ cells

The functional status of anti-lysozyme B cells from the zinc-induced double-transgenic mice was assessed by adoptive transfer (Fig 2*c*) In contrast to B cells from immunoglobulic-transgenic or uninduced ML3 × MD3 double-transgenic mice, B cells from the mice exposed to zinc for 4 days responded poorly when challenged with lysozyme coupled to a foreign carrier (horse red blood cells, HRBC) following adoptive transfer into irradiated nontransgenic recipients together with HRBC-primed helper cells In other words, the zinc-induced rise in serum lysozyme concentration and B-cell receptor occupancy led to changes in receptor phenotype and function in mature, peripheral B lymphocytes from adult ML3 × MD3 animals which were identical to those described previously in silenced B cells from ML5 × MD3 double-transgenic mice The functionally silenced state of the B-cells cannot be accounted for simply by 'blocking' of antigen receptors with lysozyme for two reasons first, less than 50% of the receptors were occupied in ML5 × MD3 double-transgenic mice (Fig 1*b*), and second, artificially 'blocking' half the receptors with lysozyme *in vitro* before adoptive transfer failed to alter the responsiveness of immunoglobulin-transgenic cells (Fig 2*d*)

Transfer of nontolerant B cells

The apparent susceptibility of mature peripheral B cells to IgM receptor down-regulation and silencing was examined in a second way, by transferring nontolerant spleen cells from immunoglobulin-transgenic mice into irradiated ML5 (high lysozyme) transgenic recipients or nontransgenic littermates (Fig 3) The possibility of a donor T-cell response to recipient lysozyme was minimized by using C57BL/6 strain donors and recipients, which are low responders to lysozyme[29] Between 5 and 10% of the injected lysozyme-binding B cells homed to the spleen of both types of recipients In the case of lysozyme transgenic recipients, the cells exhibited a 10-fold down-regulation of surface IgM as early as 20 h after transfer (Fig 3*a*) and persisted in this state for at least 10 days (data not shown) The functional capacity of the transferred B cells was examined by co-injecting the immunoglobulin-transgenic spleen cells with spleen cells from nontransgenic donors primed to HRBC to act

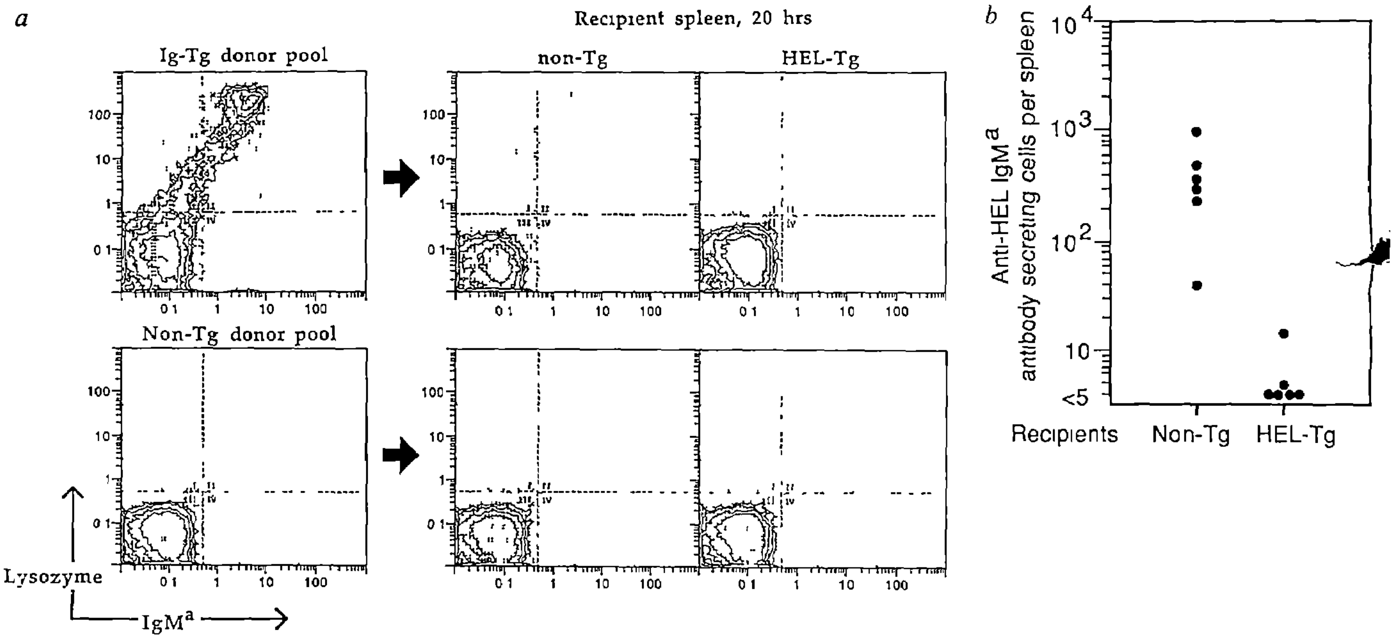


FIG 3 Transfer of immunoglobulin-transgenic spleen cells into ML5 HEL-transgenic recipients leads to rapid downregulation of membrane IgM and induction of tolerance *a*, For FACS analysis, 10^7 spleen cells from adult MD3 immunoglobulin-transgenic mice or nontransgenic controls were injected into 750-rad-irradiated ML5 transgenic mice or nontransgenic littermates, and recipient spleen cells analysed by two-colour FACS for HEL-binding against IgM at 20 h (*a*), 2 5 days or 10 days after transfer Duplicate recipients at each timepoint gave similar results to *a* *b*, For antibody responses, 10^6 immunoglobulin-transgenic cells were co-injected with 5×10^6 HRBC-primed C57BL/6 spleen cells into irradiated ML5-transgenic mice or nontransgenic littermates, left for two days, and then challenged with 2×10^8 HEL-HRBC intravenously Antibody responses in individual recipients were measured as anti-HEL $\mathrm{IgM}^{\mathrm{a}}$ antibody-secreting cells in the spleen by spot-ELISA[50] five days after challenge

METHODS All donors and recipients were adult animals of C57BL/6 genetic background Antibody secreting cells were measured by spot ELISA[53], in 24-well plastic trays coated with 1 mg ml^{-1} HEL Spots of bound antibody were revealed with biotinylated anti-$\mathrm{IgM}^{\mathrm{a}}$ antibody RS3 1 followed by avidin-alkaline phosphatase a source of helper T cells Two days after cell transfer, the cipient mice were challenged with lysozyme coupled to HRBC HEL-HRBC) In contrast to the good response obtained after parking' in nontransgenic hosts, immunoglobulin-transgenic B lls parked in HEL-transgenic recipients failed to mount an ntibody response, as measured either by antibody-secreting ells in the spleen (Fig 3*b*) or by serum antibody titres (data ot shown)

olerance and IgM-down-regulation

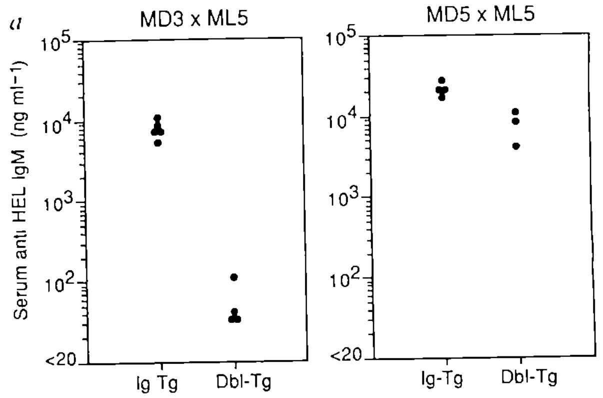
he results from the low-lysozyme double-transgenic mice, the ffects of zinc induction and the cell transfer experiments emonstrate a good correlation between selective down-regulaon of membrane IgM but not IgD and clonal silencing of the cell The lack of down-regulation of membrane IgD cannot e explained in terms of failure of IgD to bind lysozyme as B ells from lines of immunoglobulin-transgenic mice expressing nti-lysozyme IgD alone bind lysozyme as efficiently as B cells rom immunoglobulin-transgenic mice expressing IgM-alone, nd B cells from double-transgenic mice expressing IgM alone how a more marked decrease in lysozyme binding which is directly proportional to the down-regulation of membrane IgM unpublished observations) Thus the 4–10 fold decrease in ysozyme binding that accompanies the 10–50 fold down-regulaion of IgM in tolerant double-transgenic mice expressing IgM nd IgD (Figs 2*a*, 4*b*) can best be explained by binding of ysozyme to unchanged levels of membrane IgD The degree of eduction in lysozyme binding observed may reflect both the ct that a subpopulation of the B cells do not express IgD (see low), and that in the absence of any down-regulation, IgM may be expressed at higher density than IgD

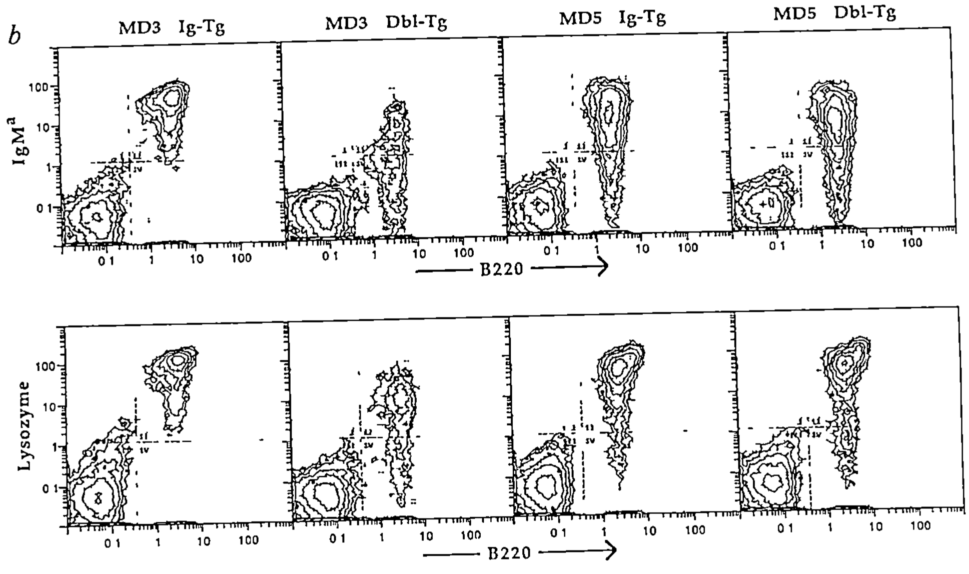
A close relationship between selective down-regulation of membrane IgM and B-cell tolerance was also found in a eciprocal experimental approach, which involved mating different lines of anti-lysozyme IgM+IgD immunoglobulin-ransgenic mice to the original (high lysozyme) ML5 transgenic ine Four out of the five double-transgenic combinations yielded imilar results to ML5×MD3 (a detailed comparison of all the ines will be described elsewhere) Double-transgenic offspring from the fifth immunoglobulin-transgenic line, MD5, were xceptional in that they failed to exhibit silencing of anti-ysozyme B cells, and continued to secrete high levels of transgene-encoded anti-lysozyme IgM into the serum (Fig 4*a*) FACS analysis of spleen cells from both MD5 immunoglobulin- and double-transgenic mice showed that the B cells express high levels of lysozyme-binding IgM and IgD, and that the failure of silencing in the double-transgenic mice was associated with minimal down-regulation of transgene-encoded membrane IgM (Fig 4*b*) The explanation for the lack of membrane IgM down-regulation and B cell silencing in the MD5 line is not known, but may be related to a failure of allelic exclusion between the transgene and the endogenous heavy chain genes, which also appears to be unique to this line

IgM-down-regulation in nontransgenic mice

In spleens from adult nontransgenic mice, three phenotypic populations of B cells have been defined on the basis of IgM and IgD expression[30] B cells expressing little or no IgD and high levels of IgM comprise one subset, designated 'population III' (Fig 5), which is primarily composed of marginal zone B cells in addition to small numbers of immature B cells and Ly1 B cells[31,32] The other two subsets, 'populations I and II' are both relatively long-lived, IgD-positive, recirculating cells found in the follicular mantle zone[31] and are distinguished only on the basis of their membrane IgM levels which vary over a 100-fold range (Fig 5) Low expression of membrane IgM on population I follicular B cells seems to be a post-translational phenomenon, involving increased surface IgM turnover and/or decreased transport to the cell surface[33], but the underlying explanation for such changes in receptor expression is unknown

In the transgenic mice, interaction with a threshold level of self-antigen induced a selective downregulation of membrane IgM and converted B cells with a population II phenotype into population I type cells (Fig 5) The apparent equivalence of the IgD-positive B cells from immunoglobulin- and double-transgenic mice with populations II and I respectively is borne out by the identical expression of non-immunoglobulin B-cell





IG 4 Failure of tolerance and absence of downregulation of membrane IgM in MD5 × ML5 double-transgenic mice *a*, Spontaneous secretion of anti-lysozyme IgM measured in the serum of MD3×ML5 or MD5×ML5 double-transgenic mice or immunoglobulin-transgenic littermates *b*, Spleen cells from MD3×ML5 or MD5×ML5 double-transgenic mice or immunoglobulin-transgenic littermates analysed by FACS for expression of transgene-encoded IgM^a (top), or lysozyme-binding immunoglobulin (bottom) on B220-positive B cells

METHODS Serum anti-HEL IgM antibody was measured as described in Fig 1, except that sheep anti-mouse IgM-alkaline phosphatase was used as the developing reagent FACS analysis was as described previously, IgM^a and B220 were detected with biotinylated RS3 1 and fluoresceinated RA3-6B2 antibodies respectively

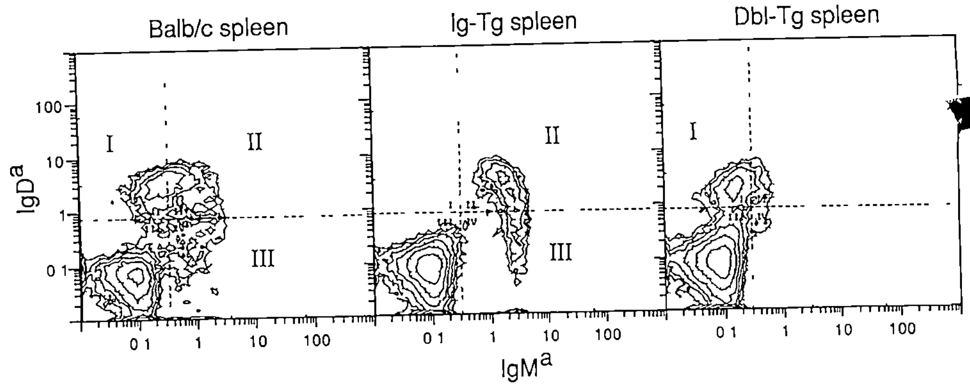


FIG 5 IgD-positive splenic B cells from immunoglobulin and double-transgenic mice are phenotypically equivalent to B cell subpopulations II and I, respectively, in nontransgenic spleen Spleen cells from MD4 immunoglobulin-transgenic or double-transgenic littermates and from an age- and sex-matched BALB/c control were stained for a-allotype IgD and IgM and analysed by FACS, as described in Fig 1 I, II, and III indicate the three predominant B-cell subpopulations defined by relative expression of membrane IgM and IgD[30] To allow consistent use of anti-allotype (transgene-specific) reagents, BALB/c mice were used as nontransgenic controls in preference to C57BL/6 mice, as identical subpopulations are observed in both strains[54 55]

markers[34] and by immunohistological studies showing that the population II and I equivalents in the transgenic mice are indeed both located in the follicular mantle zone (D Y Mason *et al*, in preparation) One interpretation of these findings is that population I and II follicular B cells normally represent a continuum of cells at one extreme, some follicular B cells have high avidity for self antigens (lowest IgM), whereas at the other extreme, B cells exist that do not bind appreciably to any self antigen (highest IgM) The similarity may also hold in functional terms as population I cells with the lowest surface IgM, like double-transgenic B cells, have in fact been found to respond poorly in primary adoptive-transfer antibody responses to foreign antigens[35]

Discussion

Mature follicular B cells expressing transgene-encoded receptors were found to respond either positively to exogenous lysozyme presented on a foreign carrier, or negatively to endogenously synthesized lysozyme These results support and extend earlier evidence for tolerance induction in mature B cells in nontransgenic mice[18-26], and raise the question of how self-reactive B cells are selectively tolerized Because the stage of B-cell development does not seem to be critical for tolerance induction either in the transgenic model or in conventional *in vivo* models[23 25], some other variable must account for the immunogenicity of exogenous lysozyme compared with the tolerogenicity of autologous lysozyme It is tempting to speculate that the factor responsible for determining whether the B cell becomes unresponsive or activated is the absence or presence of second signals derived from helper T cells during the initial contact with antigen, as originally proposed by Bretscher and Cohn[36] Thus, T cell 'help' would be absent during the initial encounter of B cells with above-threshold lysozyme concentrations in the zinc induction experiments, owing to the fact that the low levels of lysozyme expressed in uninduced ML3 mice are still sufficient to render the helper T cell compartment tolerant (S Adelstein *et al*, manuscript in preparation) Similarly, signals from helper T cells would be deficient in the parking experiments during the two days before challenge with HEL-HRBC because the C57BL/6 donor T cells, although not necessarily tolerant to recipient lysozyme, are unable to respond to lysozyme owing to their low-responder genotype[29] In both cases, subsequent encounter with HEL-HRBC would therefore have failed to elicit an antibody response, despite provision of optimal T-cell help, because the B cells had by then become intrinsically unresponsive

The capacity of a threshold concentration of lysozyme corresponding to a receptor occupancy of between 4 5 and 46% to silence mature peripheral B cells provides a straightforward mechanism for preventing the generation of high affinity autoantibodies by hypermutation, and conversely, helps to explain the common occurrence of low affinity autoantibodies in normal individuals The demonstration of a B-cell subset with the phenotype (IgM^{low}, IgD^{hi}) of functionally silenced cells in the peripheral lymphoid tissue of nontransgenic mice lends weight to the possibility that such a mechanism may indeed play a major role in maintaining self-tolerance within the B-cell repertoire

The close relationship between down-regulation of membrane IgM and induction of an unresponsive state in the B cell is reminiscent of ligand-induced receptor downregulation and desensitization in other biological systems[37-40] It is unlikely that the decreased IgM receptor level itself accounts for the unresponsive state of the cell, as membrane IgD is still expressed at high levels and on its own is fully capable of mediating B-cell activation in immunoglobulin-transgenic mice (R Brink *et al*, in preparation) as well as in other models[41,42] Ligand-induced desensitization of IgM and IgD antigen receptors, in the absence of downregulation, has been shown to occur in mature B cells *in vitro*[43] By analogy with other signal-transduction systems[37-40,44,45] biochemical changes affecting subsequent steps in the signalling pathway (reviewed in refs 42, 46, 47), such as phosphorylation or other alterations in membrane immunoglobulin-associated CD3-homologues[48-50], could explain both the selective change in IgM-expression and the unresponsive state of the B cell A detailed understanding of how tolerance mechanisms act on mature peripheral B cells may prove important for controlling pathological antibody responses in allergy and autoimmunity □

The guanosine binding site of the *Tetrahymena* ribozyme

rançois Michel*, Maya Hanna, Rachel Green, David P. Bartel & Jack W. Szostak

epartment of Molecular Biology, Massachusetts General Hospital, Boston, Massachusetts 02114, USA

he self-splicing Group I introns have a highly pecific binding site for the substrate guanosine lutant versions of the *Tetrahymena* ribozyme ave been used in combination with guanosine nalogues to identify the nucleotide in the ribozyme hat is primarily responsible for recognition of the uanine base

NE of the substrates of the class of ribozymes known as the roup I introns is the nucleoside guanosine, an understanding f how this substrate is bound is essential to an understanding f the mechanism of catalysis of these RNA enzymes All reactions performed by Group I introns seem to involve the binding ither of guanosine or an internal G residue The first step of elf-splicing requires the specific binding of free guanosine, hich becomes covalently added to the 5′ end of the intron after leavage of the 5′ intron–exon junction[1] Group I introns invariably end with a 3′ terminal G residue (for a review, see ref 2), hich is required for efficient cleavage and ligation at the 3′ tron–exon junction[3] Reactions that mimic circularization of e excised intron also require guanosine[4]

It is clear that the Group I introns contain a well-defined uanosine-binding site Bass and Cech[5 6] used guanosine nalogues to show that both the ribose and guanine moieties of uanosine are specifically recognized by the *Tetrahymena* intron ere we present evidence that a phylogenetically invariant uanine residue in the highly conserved stem P7 in the catalytic ore of the intron is the part of the guanosine binding site that nteracts with and recognizes the guanine base

ase-paired stem constrains binding-site location

he site that binds the 3′-terminal G residue of the *Tetrahymena* ibozyme must be physically close to the site that binds the 3′ ntron–exon junction We therefore first attempted to clarify the ature of the 3′ intron–exon junction binding site A part of the ntron called the internal guide sequence (IGS) is known to ind the 5′ exon, formation of a base-paired stem (P10) between he 3′ exon and the IGS has been proposed to align the two xons for ligation (ref 7, and Fig 1) The P10 pairing is not resent in all Group I introns, however, and can be disrupted in the *Tetrahymena* intron without affecting splicing[8] These data indicate that the 3′ intron-exon junction could be recognized by redundant mechanisms A probable candidate for such an additional interaction is the recently identified P9 0 pairing between the two nucleotides immediately preceding the 3′ terminal G residue, and two nucleotides in the segment (J7-9) connecting base-paired stems P7 and P9 (F Michel, P Netter, M Xu and D Shub, manuscript submitted) The P9 0 pairing was identified by sequence comparison analysis, and is widespread although not universal in the Group I introns

By mutationally disrupting the P9 0 and P10 putative pairings, both separately and together (Fig 1 and Table 1), we found that both contribute to binding the 3′ intron–exon junction in the *Tetrahymena* intron None of these mutations had marked effects on the rate of 5′ cleavage Mutants with only the P9 0 or the P10 pairing disrupted had relatively minor effects on 3′ splicing By contrast, when both P9 0 and P10 pairing were disrupted, 3′ splicing was strongly affected, these introns accumulate 5′ exon and intron-3′ exon during splicing Restoring either the P9 0 or P10 pairing by compensatory mutations invariably alleviates the defect in 3′ cleavage and ligation Thus,

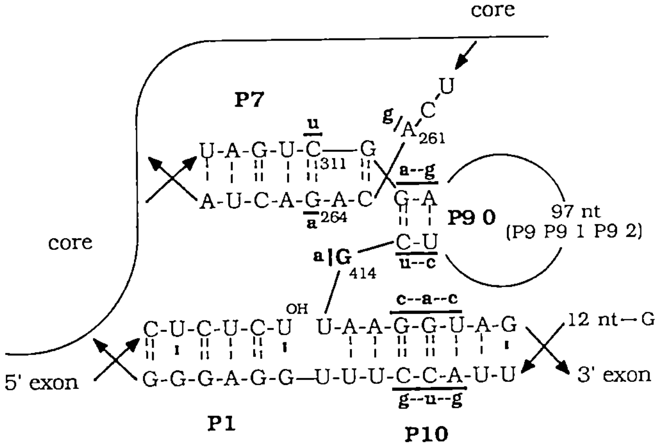

FIG 1 Secondary structure elements surrounding the 3′ terminal G (position 414) of the *Tetrahymena* intron P1, P10, P7 and P9 0 are base-paired segments (See refs 9-11 and 23 for nomenclature and a more complete secondary structure model of the intron) The situation depicted is just before the ligation step Mutations introduced in this work are indicated in bold, lower case letters next to the nucleotides that were substituted nt, Nucleotide

binding of the 3′ intron–exon junction is ensured by base pairing of the nucleotides immediately flanking the terminal G residue to two distinct regions of the *Tetrahymena* intron. These two pairings strongly constrain the possible locations of the guanosine binding site.

Defective recognition of the 3′ terminal G

We searched for an intron residue that might be involved in recognition of the 3′ terminal G by screening mutants for the loss of ability to distinguish between a G and an A residue at the 3′ end of the intron. Changing the 3′ terminal G residue of the *Tetrahymena* intron (position 414) to a U or C residue results in normal cleavage at the 5′ intron–exon junction, but greatly reduces the rates of 3′ cleavage and ligation[3]. Under the same splicing conditions, we found that changing the 3′ terminal G to an A residue led to delayed (but still accurate) 3′ splicing.

Because all Group I introns end in a G residue we surmised that any nucleotide involved in recognition of this 3′ terminal G was probably one of the very few residues that are conserved in all Group I introns. There are only two such invariant nucleotides close to P9.0 in the secondary structure of the *Tetrahymena* intron[2,9–11]. These are residue A at position 261 (A261) in the joining segment J6/7, which we mutated to G (mutation A261→G), and residue G264, which is part of the very highly conserved paired stem P7: the G264·C311 pair was mutated to A·U (mutation A·U).

Both the A261→G and the A·U mutations greatly reduced the rate of 5′ cleavage, but at high concentrations of GTP, cleavage was efficient enough to allow study of 3′ splicing. In an A261→G context, the rate of 3′ splicing was further decreased when the 3′ terminal G residue was mutated to A (Fig. 2*a*, *c*), showing that position 261 is not involved in recognition of the 3′ terminal G. The A·U mutation, by contrast, greatly decreased the rate of 3′ cleavage, but there was only a slight further decrease on changing the 3′ terminal G residue to A (Fig. 2*b*, *d*). Either recognition of the 3′ terminal nucleotide was no longer rate-limiting for the A·U introns, or they failed to distinguish G from A.

A guanosine analogue restores 5′ cleavage

If the same binding site is used for both the 3′ terminal G residue and the free guanosine used in 5′ cleavage, the A·U mutant should have a greatly reduced affinity for free guanosine. Although we were not able to measure guanosine binding (dissociation constant, K_d) directly, we were able to measure the Michaelis constant K_m (depending on the precise reaction kinetics, K_m need not equal K_d), and we found that the K_m for 5′ cleavage of the A·U intron with guanosine is 3.0 mM; this is two orders of magnitude higher than the K_m for 5′ cleavage of the wild-type intron, which is 0.024 mM (Fig. 3*a*, Table 2). I addition, the maximum initial rate of the reaction is much re duced (0.0034 min^{-1} instead of 0.29 min^{-1}), again, the catalyti constant K_{cat} need not reflect the chemical step of catalysis, bu the simplest interpretation of these results is that the guanosin is not only poorly bound, but incorrectly orientated.

A model of possible hydrogen-bonding interactions betwee guanosine and the G264·C311 base pair is shown in Fig. 4. I this model, the G264→A mutation would lead to a steric clas between two hydrogen-bond donors, resulting in both decrease affinity and incorrect positioning. To test this model, we synthesized the guanosine analogue 2-aminopurine ribonucleosid (2AP), which differs from guanosine in its distribution of hydrogen-bond donors and acceptors. The interactions proposed fo the binding of 2AP to the A of an A·U base pair and for th binding of G to G·C are isosteric (Fig. 4). When we used 2A in splicing reactions, we found that wild-type introns preferre G to 2AP, but A·U introns preferred 2AP to G (Table 2, Fig. 3*b*). The ability of the A·U mutant to perform 5′ cleavage wa fully restored at high concentrations of 2AP, and the K_m of th A·U mutant with 2AP (two hydrogen bonds, $K_m = 0.43$ mM) is

TABLE 1 Effect of disruption of the P9.0 and P10 pairings on exon ligati

P10	P9.0			
	Wild type	5′-disrupted	3′-disrupted	Restore
Wild type	0.91	0.42	0.60	0.85
5′-disrupted	0.74	0.05	0.011	0.20
3′-disrupted	0.92	0.10	0.31	0.88
Restored	0.96	0.59	0.73	0.94

Mutations introduced to disrupt the P9.0 and P10 pairings are shown Fig. 1. Numbers shown are the fraction of 5′ cleaved exon that has beco ligated to 3′ exon. Reactions were for 60 s, the fraction of reacted precurs varied from 22–87% depending on the mutant examined. Missplicing w minimal for all mutants, as the only band of significant intensity inbetwe linear intron (~400 nucleotides (nt)) and 5′ exon (57 nt) was the ba generated by ligated exons (101 nt). The only exception was the muta disrupted through mutation of the 3′ branches of both P9.0 and P10: a ba migrating to a position corresponding to 64 nt was observed that amount to ~20% of the sum of ligated exons and 5′ exon. Mutations were co structed by casette mutagenesis as previously described[19]. Transcriptic gel purification of [^{32}P]GTP-labelled full-length transcripts, splicing conditio (5 mM $MgCl_2$, 200 mM $NH_4C_2H_3O_2$, 20 mM Tris buffer pH 7.5, 0.02% SD 30 °C, 20-min preincubation, 2 mM GTP) and gel electrophoresis were esse tially as described previously[3]. The radioactivity in electrophoretic banc was determined by direct scanning with a Betagen counter (Walthar Massachusetts) and converted to molar amounts by correcting for t number of G residues.

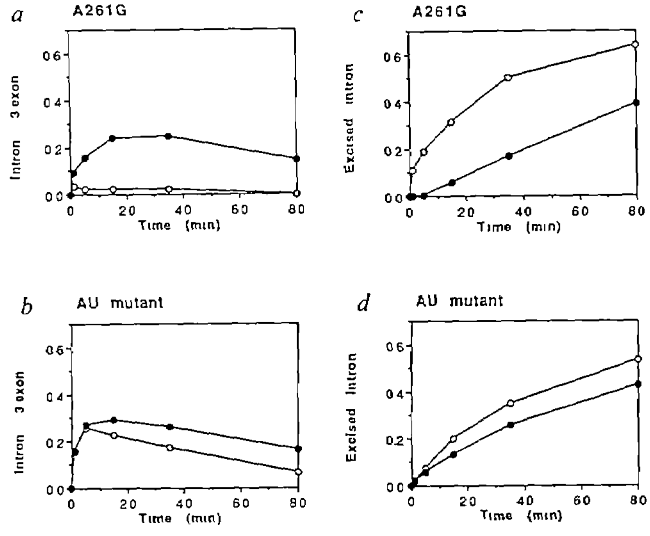

FIG. 2 Ability of two mutant versions of the intron to distinguish between 3′ terminal G (○) and 3′ terminal A (●). *a*, *b*, Accumulation of the intron–3′ exon intermediate, expressed as fraction of total intron. *a*, A261G mutant. This intermediate does not accumulate with a 3′ terminal G, but does with a 3′ terminal A. *b*, AU mutant. This intermediate accumulates with similar kinetics whether or not the 3′ terminal residue is A or G. *c*, *d*, Accumulation of excised intron after 3′ cleavage. *c*, A261G mutant. Accumulation is delayed when the 3′ terminal residue is A rather than G. *d*, AU mutant. Product accumulates with similar kinetics with either 3′ terminal A or G.
METHODS. Splicing was carried out in 15 mM $MgCl_2$, 40 mM Tris buffer pH 7.5, 2 mM spermidine, 5 mM DTT at 37 °C. Reactions were started by addition of GTP to a final concentration of 2 mM (<10% of precursor RNA had reacted after 80 min in controls without GTP).

ver than that of either the A U mutant with guanosine (one drogen bond, steric clash, $K_m = 3\ 0$ mM) or the wild-type ron with 2AP (one hydrogen bond, no steric clash, K_m = mM)

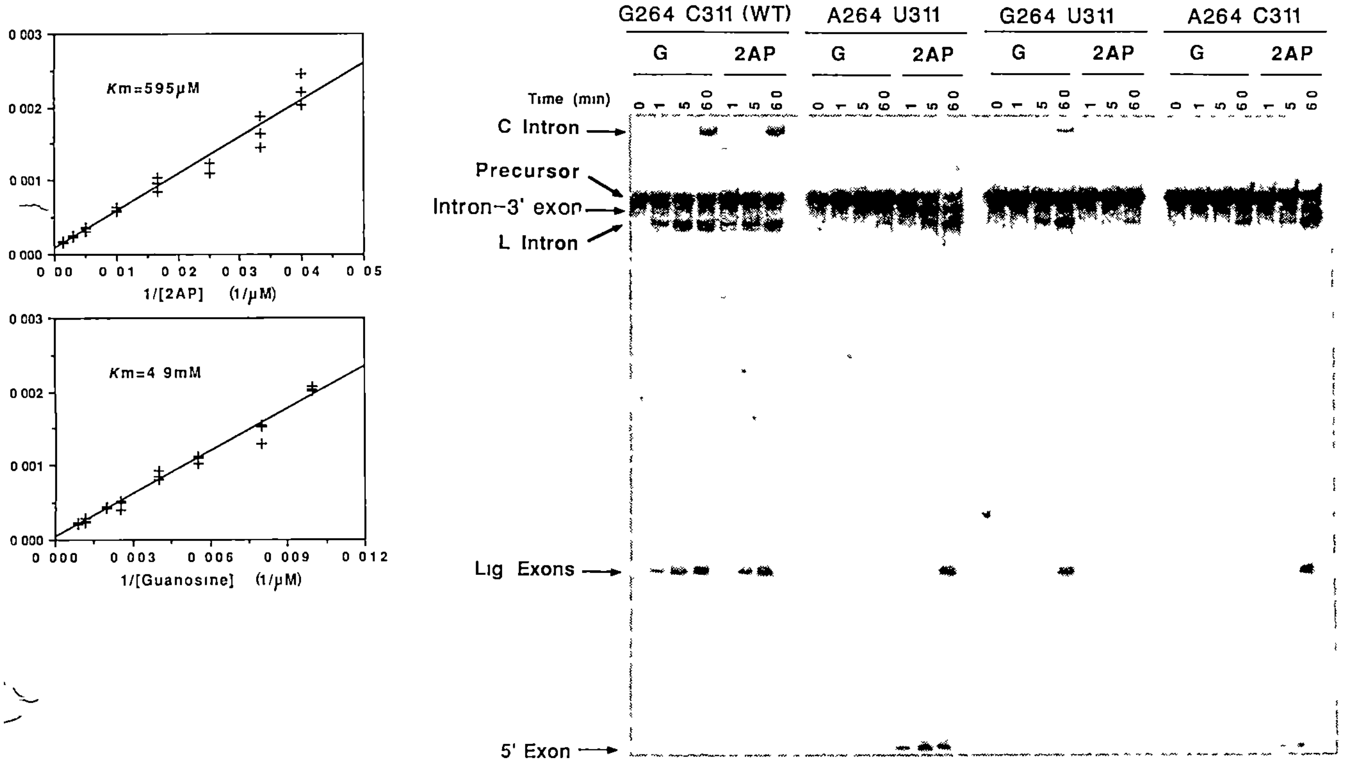
We used single mutants to show that the G residue of the :64 C311 base pair is responsible for discriminating between anosine and 2AP A G C-to-G U mutation still allowed some icing with guanosine, but almost no splicing was detectable :h 2AP (Fig 3*b*) By contrast, a G C to A C mutation blocked icing with guanosine, but allowed cleavage by 2AP

e A·U mutation affects inhibition by arginine

e amino acid arginine inhibits self-splicing of the *Tetrahymena* ron by competing with guanosine[12] Yarus[12] proposed that : guanidino group of arginine can substitute for the two donor oups of guanine (Fig 4) If so, splicing of the A U mutant ould not be inhibited by arginine, for the same reason that s mutant binds guanosine so poorly We found that splicing the wild-type intron was strikingly inhibited by 10 mM ginine, whereas no effect was seen on the activity of the A U mutant (Fig 3*c*) Citrulline is an analogue of arginine with a substitution in the guanidino group which should enable it to bind to the A U mutant intron (Fig 4) Citrulline was reported to be only a very weak inhibitor of splicing[13] and we observed only slight inhibition of splicing of the wild-type intron at 300 mM citrulline But splicing of the A U mutant was significantly more inhibited by citrulline (Fig 3*c*), as predicted by the model for arginine binding

2-aminopurine in exon ligation

If there is one binding site for both free guanosine and the 3′ terminal G of the *Tetrahymena* intron, it should be possible to restore the A U mutant to full 3′ splicing activity by replacing the 3′ terminal G residue by 2AP Unfortunately, direct replacement of a nucleotide by an analogue in a long polynucleotide chain is not feasible at present The exons to be ligated, however, need not be covalently linked to the intron and can be quite short[14] We therefore synthesized two oligoribonucleotides that could be aligned on the IGS of the *Tetrahymena* intron One oligonucleotide represented the 5′ exon, the other represented



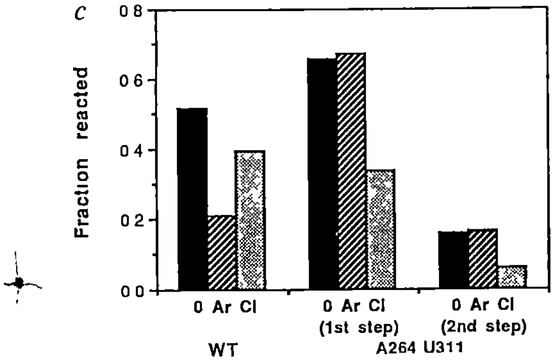


FIG 3 Splicing activity of mutant transcripts with guanosine and guanosine analogues *a*, Kinetics of 5′ cleavage of the A U mutant with guanosine (lower panel) and 2AP (upper panel) V_0 is the initial rate of the reaction, expressed in counts of released product (free 5′ exon plus 5′ exon component of ligated exons) *b*, Autoradiograph of a 5% acrylamide–8 M urea gel showing splicing products generated by incubation of wild-type (WT) and mutant transcripts with guanosine and 2-aminopurine at 1 5 mM Lig, Ligated *c*, Inhibition of splicing of wild-type and mutant transcripts by arginine and citrulline Reactions were started by addition of 3 μM guanosine to wild-type intron or 50 μM 2AP to A U mutant intron together with 10 mM arginine or 300 mM citrulline Histograms show the extent of reaction at 30 min, normalized to the final amount of precursor reacted at 2 h For the A U mutant, 1st step corresponds to 5′ cleavage (intron-3′ exon in addition to excised intron), and 2nd step corresponds to both 5′ and to 3′ cleavage (excised intron only)

METHODS For K_m and V determinations, triplicate measurements were made at eight substrate concentrations RNA and ribonucleoside were separately pre-equilibrated in buffer at 30 °C for 10–30 min Reactions were started by addition of ribonucleoside and stopped by addition of an equal volume of 90% formamide, 25 mM EDTA after 1 min (WT, mutant with 2AP) or 2 h (mutant with guanosine) RNA concentrations ranged from 45–90 nM Other methods as in Table 1 he 3′ splice site The 3′ splice site oligonucleotide began with G residue, this G is equivalent to the 3′-terminal G of the ormal intron, and is cleaved off during the ligation reaction The two oligonucleotides were efficiently ligated by a shortened form of the *Tetrahymena* intron lacking both normal splice sites Fig 5) We took advantage of the fact that this reaction will un in reverse to generate a modified 3′-exon oligonucleotide eginning with 2AP an oligonucleotide representing ligated xons was cleaved by the A U mutant intron in the presence of ree 2AP

We could then compare the ability of the 3′-exon oligonucleoide beginning with G and its 2AP-substituted version to serve s 3′ splice sites As expected, the A U mutant intron was unable o ligate a 3′ exon beginning with G, but was able to ligate a 3′ xon beginning with 2AP (Fig 5*c*) By contrast, the 2AP oligonucleotide was not used by the wild-type intron Therefore, in reaction that mimics 3′ cleavage and exon ligation, the G C nd A U versions of the *Tetrahymena* intron show the same preferences for guanosine and 2AP as they do in 5′ cleavage This, together with the fact that the A U mutant distinguishes poorly between G and A at the 3′ intron–exon junction, shows hat free guanosine and the 3′ terminal G are not only recognized by the same nucleotide of the intron but most probably bind it by means of the same type of G G base pair

Discussion

The guanosine-to-G C base triple postulated in Fig 4 readily accounts for data reported by Bass and Cech[5] concerning the ability of the *Tetrahymena* intron to use guanosine analogues Both 1-methylguanosine and *N*-2-methylguanosine are poor ubstrates for splicing, as expected from the involvement of positions 1 and 2 in hydrogen bonding By contrast, positions 7 and 8, which are not involved, can be substituted without effect We have attempted to determine the role of position 6 by comparing the abilities of 2AP and 2,6-diaminopurine ribonucleosides to participate in 5′-cleavage if 06 of guanosine is nvolved in hydrogen bonding, replacing it by a donor group would presumably create a steric clash, and therefore be highly detrimental Our experiments (Table 2), however, show that 2,6-diaminopurine is nearly as effective as 2AP at saturating concentrations, whether wild-type or mutant introns are involved It is possible that only two hydrogen bonds are formed between the bound guanine base and the intron, with stacking nteractions also contributing to the high affinity and highly specific recognition of guanosine The specificity of ribonuclease T1 towards guanine nucleotides rests similarly on the base stacking with a tyrosine residue, in addition to the formation of two hydrogen bonds with the main chain of this protein enzyme[15] Lower stacking energies due to the loss of 06 might account for the elevated K_m of the A U mutant for 2AP (and the even higher K_m for 2,6-diaminopurine), compared with that of wild type for guanosine

It has been argued that Group I introns possess two G-binding sites[16] This suggestion stemmed from the G-exchange reactions in which a 3′-OH group of a 3′ terminal G attacks the phosphate immediately 3′ to a G residue[17,18] But our results show that there cannot be two completely separate binding sites, because the same mutation affects the G-residue requirement for both 5′ and 3′ splicing A further argument in favour of a single G-binding site in Group I introns is that all cyclization reactions involving mismatched combinations of nucleotides and binding site are subject to competition by the better-matched free nucleoside For instance, excised intron molecules carrying the A U mutation circularize slowly, and this reaction is inhibited by 2AP but not by guanosine

The interaction between guanosine and the highly conserved G C base pair in the core of the ribozyme constitutes our first glimpse of how an RNA enzyme binds a mononucleotide substrate Similar experiments with guanosine analogues and mutant introns should identify the bases involved in stacking interactions and the groups recognizing the ribose □

TABLE 2 Splicing of wild-type and mutant introns with guanosine and analogues

RNA	Purine nucleoside	K_m (mM)	V (min^{-1})	V/K_m (M^{-1} min^{-1})
Wild-type	Guanosine	0 027	0 34	12,500
		0 021	0 24	11,500
	2-Aminopurine	1 09	0 17	156
	2,6-Diaminopurine	2 2	0 14	63
		1 4	0 17	119
Mutant	Guanosine	2 4	0 0019	0 81
		3 7	0 0049	1 33
	2-Aminopurine	0 59	0 68	1,140
		0 28	0 54	1,930
	2,6-Diaminopurine	3 6	0 26	73
		1 8	0 25	139

Velocity of enzyme-catalysed reaction at infinite concentration of substrate (V) and K_m values were calculated from plots as in Fig 3*a* V is expressed as the fraction of precursor RNA converted per min, corrected for the maximum extent of reaction Reactions were for 60 s, except for mutant transcripts with guanosine (2 h) Different values for the same transcript and analogue correspond to different RNA preparations Multiple determinations with the same RNA preparation were averaged Splicing conditions were as in Table 1, and kinetic analysis as in Fig 3 Synthesis of 2-aminopurine thioguanosine (Sigma) was directly reduced to 2-aminopurine ribonucleoside with Raney nickel[20] The reaction was followed by ultraviolet spectroscopy absorption at 340 nm decreased and that at 306 nm increased A fine yellow precipitate was recovered and analysed The ultraviolet spectrum was identical to that published by Fox *et al*[20], and the NMR spectrum clearly indicated that the starting thioguanosine had been quantitatively (>99%) reduced Synthesis of 2,6-diaminopurine riboside (an initial sample was a gift of L Orgel) guanosine was quantitatively converted to 2,6-diaminopurine riboside in a silylation-amination procedure using hexamethyldisilazane and ammonia in the presence of a Lewis acid, trimethylsilyl-trifluoromethanesulphonate[21] The product was recrystallized three times from boiling water to yield fine white crystals Its NMR spectrum was identical to that found by Muraoka[22] and showed no evidence of contamination by guanosine

The barrier to recombination between *Escherichia coli* and *Salmonella typhimurium* is disrupted in mismatch-repair mutants

Christiane Rayssiguier[*], David S. Thaler[†] & Miroslav Radman[*‡]

[*] Institut Jacques Monod, 2 Place Jussieu, Tour 43, 75251 Paris-Cedex 05, France
[†] Biology Department, University of Utah, Salt Lake City, Utah 84112, USA
[‡] Laboratory of Molecular Genetics, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina 27709, USA

The requirement for DNA sequence homology in generalized genetic recombination is greatly relaxed in bacterial *mutL*, *mutS* and *mutH* mutants deficient in mismatch repair In such mutants, intergeneric recombination occurs efficiently between *Escherichia coli* and *Salmonella typhimurium*, which are ~20% divergent in DNA sequence This finding has implications for speciation, for regulating recombination between diverged repeated sequences, and for hitherto difficult interspecies hybridizations

GENERALIZED genetic recombination provides a means for the transfer or exchange of genetic information between homologous regions of DNA, as well as for the repair of DNA damage The fidelity of recombination depends on the precise formation of a hybrid or heteroduplex joint consisting of two complementary DNA strands, one contributed by each of the recombining molecules [1-4] The hybrid joint is a key structure for aligning parental sequences in genetic recombination Presumably because of the need to maintain chromosomal integrity, recombination *in vivo* requires nearly perfect homology and is abolished by as little as 10-20% sequence divergence[5,6] But heteroduplex DNA formation catalysed *in vitro* by the *E coli* RecA protein tolerates up to 30% sequence mismatches[7] Several lines of evidence indicate that the strand exchange reaction is edited by mismatch repair proteins supposed to abort or inactivate heteroduplex intermediates containing mismatched base pairs[8,9] Karimova *et al* [10] were first to propose that recombination between highly diverged sequences might be differentially inhibited by the mismatch repair system (owing to overlapping excision tracts[11-13]), this idea has since been independently proposed by others[8,9 14,15] Studies on recombination and mismatch repair in *Streptococcus pneumoniae*[16,17] and *E coli*[14,18] indicate that the marker effects on the efficiency of homologous recombination are often caused by the abortion of heteroduplex intermediates with one or few mismatches[8] Thus, the mismatch repair system might prevent recombination between partially homologous sequences and provide a functional barrier to interspecies recombination[8,9] We have now tested the prediction that mutants defective in mismatch repair can become proficient in interspecies recombination by using members of two related bacterial genera, *E coli* and *Salmonella typhimurium*, which are about 80% homologous in DNA sequence[19] Mutations in the *mutL*, *mutS* or *mutH* mutator genes inactivate methyl-directed mismatch repair of errors in DNA replication[20-22], we show that these mutations can increase intergeneric recombination in conjugational and transductional crosses by up to 1,000-fold Hence, mismatch recognition and the mismatch repair system can act as a barrier to recombination between DNAs of different species

Conjugation

Conjugation between *E coli* Hfr donors and *S typhimurium* I recipients deficient in DNA restriction (see Table 1 for stra description and the legend of Table 2 for the protocol) w conducted for 40 min on the surface of nutrient agar plate Mating was interrupted and the bacteria were replated to sele for xyl^+ or met^+ *S typhimurium* recombinants under conditio that prevented the growth of the *E coli* donor cells When th recipient cells were deficient in methyl-directed mismatch repa that is, *mutH*, *mutL*, *mutS* or *mutU*, recombinants we recovered much more frequently than when the recipients we mut^+ (Table 2) The increase in the formation of recombinan is clearly *recA* dependent (The relatively weak effect of *mut* (leading to a lack of helicase II function)[23-25] was not due the complementation by the *E coli* $mutU^+$ gene—Table 2 The co-inheritance of *xyl* and *met* markers, separated by ~13% of the bacterial genome, indicates that large fragments of th *Escherichia* genome can be integrated into the *Salmonell* recipient genome, although less frequently than in the homo specific *E coli* cross (Table 3)

Perhaps the simplest interpretation of these results is tha intergeneric recombinants arise through gene replacement, th

[*] Made by P1 transduction[58] from *E coli* GW7303 (AB1157 *uvrD260* Tn*5*), selection for kanamycin resistance (40 μg ml^{-1}) and screening for mutator and UV-sensitive phenotype

[†] Made by P22 *int3* Hft transduction from *S typhimurium* TT13479 (*recA1 srl203* Tn*10d-Cam*—which confers chloramphenicol resistance)[34], selection for chloramphenicol resistance (10 μg ml^{-1}) and screening for sensitivity to ultraviolet

usual outcome of intraspecies mating It is possible for phenotypic recombinants to arise through other mechanisms however, such as (1) recA-dependent circularization of the incoming DNA, perhaps using blocks of homology such as those found in ribosomal RNA *rrn* genes, and perpetuation of the circle as an autonomous plasmid (because the conjugated region includes the *E coli oriC* origin of replication) and (2) formation of interspecies duplications involving recombination between sequences common to both organisms[26–29]

Phenotypic recombinants resulting from plasmid or duplication formation should be less stable than recombinants resulting from gene replacement To test for the stability of the xyl^+ recombinants, colonies from each cross were streaked on indicator plates Sectoring of the originally red colonies to white (the phenotype of the recipient before conjugation) or to dark red (the phenotype expected if multiple copies of the gene are present) indicates an unstable phenotypic recombinant The fractions of stable recombinants are given in Table 3 and range from 1 of 35 for *mutS* recipients to 19 of 35 for *mutU* recipients and 33 of 34 for mut^+ recipients If the recombinant frequencies in Table 2 are corrected for the fraction of unstable recombinants, the frequencies of stable recombinants from mut^- recipients range from 2×10^{-5} (*mutU*) to 7×10^{-4} (*mutL*), an increase of one to three orders of magnitude over the frequencies obtained with mut^+ recipients The highest frequencies of recombinants came from *mutL* and *mutS* recipients which could be a result of the involvement of the MutL and MutS proteins in the first step of the mismatch repair process[30] For example, it could be that the binding of these mismatch repair proteins to mismatch-containing DNA is sufficient to disrupt recombination even under conditions of complete DNA methylation Alternatively, it could be that the incoming strands are undermethylated (perhaps newly synthesized)[31] or that formation of partially homologous heteroduplex DNA involves extensive DNA synthesis in the flanking regions creating hemimethylated regions which would be substrates for normal mismatch repair activity

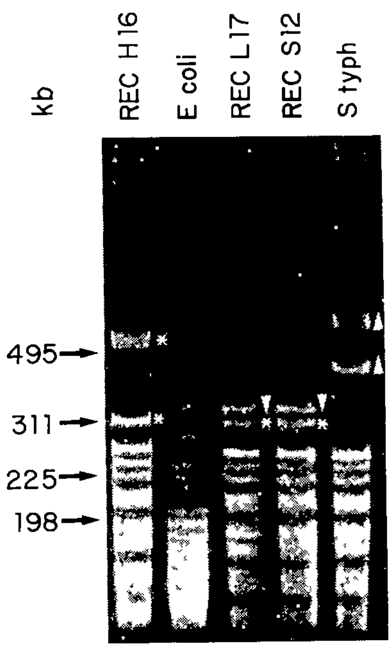

FIG 2 Restriction pattern of intergeneric recombinants from *E coli* Hfr and *S typhimurium* F^- crosses Three stable xyl^+ met^+ recombinants (REC) were selected from crosses between *E coli* Hfr *PK3* and *S typhimurium* F^- recipients which were either *mutH* (for REC H16), *mutL* (for REC L17) or *mutS* (for REC S12) For REC L17, the original *S typhimurium mutL* Tn*10* locus was replaced by the $mutL^+$ locus from *E coli*, as shown genetically in Table 3 △, Parental *S typhimurium* F^- DNA fragments lost in recombinants, ▽, DNA fragment from recombinant genomes co-migrating with a parental *E coli* Hfr donor DNA fragment, *, Non-parental DNA fragments Fragment size markers are yeast *S cerevisiae* no 334 chromosomes IX, III, VI and I Kb, kilobases

METHODS Bacteria (10 ml) were grown in Luria Bertani medium to 1 5–2 × 10^8 cells ml^{-1}, chloramphenicol was added to 180 μg ml^{-1} and incubation was continued for 1 h The bacteria were chilled, pelleted at 4 °C, resuspended in 10 ml solution I (10 mM Tris-HCl, pH 7 6, 1 M NaCl), pelleted again, and resuspended in 1 5 ml solution I They were warmed to 40 °C and an equal volume of 1 5% low-melting-point agarose was added The mixture was put in Tygon tubing, allowed to solidify, and extruded into an equal volume of lysis solution I (6 mM Tris-HCl, pH 7 6, 1 M NaCl, 100 mM EDTA, pH 7 5, 0 5% Brij 35, 0 2% deoxycholate, 0 5% sarcosyl, 1 mg ml^{-1} lysozyme, 0 2 mg ml^{-1} bovine pancreatic RNase) and incubated overnight at 37 °C with gentle shaking (With these amounts, about 25 plugs with 0 5 μg DNA per plug can be made) The plugs were then put in an equal volume of lysis solution II (0 5 M EDTA, pH 9 3, 1% lauroyl sarcosine, 1 mg ml^{-1} proteinase K) and incubated for 2 days at 50 °C The lysis solution II was replaced and the plugs were stored at 4 °C until used Plugs were then put in 15 ml TAFE buffer (10 mM Tris buffer, 4 37 mM glacial acetic acid, 0 5 mM free-acid EDTA) at room temperature for 1–2 h with gentle inversion of the tubes They were then put in new TAFE buffer with 5 mM phenylmethylsulphonyl fluoride (PMSF) and kept for another hour in the same conditions and then successively in 7 ml TE (10 mM Tris-HCl, pH 7 6, 1 mM EDTA, pH8) for 15 min with gentle inversion of the tubes and in *Spe*I-restriction buffer containing 2 mM PMSF for 10 min at 37 °C Ten units of *Spe*I enzyme (New England Biolabs) were then added to each plug, which was incubated overnight at 37 °C The plugs were then put in transverse alternating-field electrophoresis (TAFE) buffer and then in wells of 1 3% agarose gel and sealed with 1 5% agarose in TE Electrophoresis in a Beckman Gene Line TAFE system was at 220 V with two switch pulses of 25 s each for 21 h at 14 °C The gel was then stained in 0 5 μg ml^{-1} ethidium bromide, destained, and illuminated with ultraviolet light The low-melting-point agarose, the agarose and the TAFE buffer were Beckman Gene Line products The experiment was done in the Beckman Instruments Spinco Division in Palo Alto

Heterospecific crosses involved *E coli* Hfr PK3 or PK3 *mutU* and *S typhimurium* F$^-$ SL4213 *mut*$^+$, *mutH*, *mutL*, *mutS*, *mutU* or F$^-$ SL4213 (*mut*$^+$ or *mut*) *recA*1 (see Table 1) Homospecific crosses involved *E coli* Hfr PK3 or PK3 *mutU* and *E coli* F$^-$ AB1157 Log-phase bacteria were mixed in a 1 1 (Hfr F$^-$) ratio and immediately deposited on a sterile 0 45-μm pore size filter (Schleicher and Schuel) which was incubated on prewarmed, rich-medium agar After 40 min at 37 °C, the conjugants were resuspended in 10^{-2} M $MgSO_4$ and viciously separated by vortexing The exconjugants were then plated on M63 synthetic medium[58] either lacking methionine to select for *met*$^+$ recombinants or containing xylose as the sole carbon source to select for *xyl*$^+$ recombinants The Hfr donor cells were doubly counterselected by 25 μg ml^{-1} streptomycin and, in the case of intergeneric conjugation, by withholding threonine and leucine Amino acids were added to a final concentration of 100 μg ml^{-1}, thiamine to 30 μg ml^{-1} and xylose to 0 4% Because of late appearance of intergeneric recombinants from *mut*$^+$ and *mutU* crosses, all recombinants were scored after 88 h of incubation Recombination frequencies (*xyl*$^+$ or *metE*$^+$*metA*$^+$) are expressed per Hfr donor after subtracting unmated revertants Each number represents the mean of two to four independent experiments (the range was up to fourfold)

This conclusion follows from the evidence that the MutH protein recognizes and cleaves unmethylated GATC sequences in the course of methyl-directed mismatch repair[30,32] Note, however, that the requirement for unmethylated GATC sequences and MutH protein is alleviated when strand discontinuities flank the mismatch-containing region[30,32]

To assess whether *Escherichia mut*$^+$ genes replaced *Salmonella mut*$^-$ genes, we monitored the transposon (Tn) insertions in the *Salmonella mut* genes if the functional *E coli mut*$^+$ gene replaced the resident Tn-bearing *mut* gene, then the recombinant will have lost both its Tn-borne drug resistance and its mutator character This was so for seven out of eight stable *xyl*$^+$ *met*$^+$ recombinants from the cross with *S typhimurium mutL* Tn*10* as the recipient, indicating that except in one recombinant, *Escherichia* sequences had replaced *Salmonella* sequences for ~5 min beyond the last selected gene (*metA*) into the *mutL* region (see Fig 1) None of 27 unstable *xyl*$^+$ *met*$^+$ recombinants from the same cross lost drug resistance or the mutator phenotype (Table 3)

In the cross with *S typhimurium mutU* Tn*5* as the recipient, the *mutU* gene was replaced in all of the 19 stable *xyl*$^+$ recombinants (17 of which were also *met*$^+$ the *xyl* and *met* loci flank *mutU*, see Fig 1) Also, out of 16 unstable recombinants, 3 also showed *mutU* replacement, indicating that coincident replacement and duplication occurred None of the *xyl*$^+$ *met*$^+$ recombinants from *mutS* Tn*10* and *mutH* Tn*5* crosses showed transposon loss or *mut*-gene replacement, because mating was interrupted at 40 min and the *mutS*-*mutH* chromosomal region of genes was therefore unable to be transferred (see Fig 1) The stability of *xyl*$^+$ recombinants from *mut*$^+$ and *mutU* crosses does not prove that gene replacement occurs because heterospecific duplications could be stable owing to very rare homeologous recombination in *mut*$^+$ and *mutU* strains (Table 2)

Additional evidence for the physical linkage of *E coli* and *typhimurium* DNA sequences comes from the study of restrictio enzyme digests of parental and recombinant genomes DNA the parental strains and three stable recombinants (one ea from *mutH*, *mutL* and *mutS* crosses) was cut with *SpeI* enzym (Fig 2) The two largest fragments (together, ~1 megabas from parental *S typhimurium* recipient are lost in all thre recombinants and each of the recombinants has at least on nonparental fragment, which presumably contains an inte species junction Two of the recombinants have a large fragme which co-migrates with a large *E coli* fragment

Transduction

Transduction experiments were conducted by using phage P2 to move either *E coli* or *S typhimurium* histidine operon sequences between two *S typhimurium* strains The various recipient carried insertion sequences—IS*200* (ref 33) for the experiment of Table 4A and Tn*10-dCam* (ref 34) for those in Table 4B—in the *hisD* gene and also a deletion in an unlinked locu (*proA, B*) essential for proline biosynthesis The donor fo heterospecific transduction had a deletion of most of the *hi* locus[35], but was a histidine prototroph because it harboured 150-kilobase (kb) *his*$^+$ F′ episome from *E coli* Thus, the *hi* locus in the donor strain was uniquely encoded by *E co* sequences, whereas the *pro* locus was the normal *S typhimuriu* sequence Transducing lysate for homospecific crosses was prepared on wild-type *S typhimurium* and thus containe *S typhimurium* sequences at both the *his* and the *pro* locus comparison of the *hisD*$^+$ *proA*$^+$*B*$^+$ transduction ratios from th two lysates gives a measure of the efficiency of interspecie recombination relative to intraspecies recombination Th results (Table 4) are qualitatively similar to the results of conjugation experiments, in that *mutL* and *mutS* have the stronges effect and *mutU* the smallest effect Because the *E coli* sequence used in these transduction experiments were obtained from a episome present in *S typhimurium*, the effect of the mismatc repair system must be related only to sequence difference between the species rather than to a species-specific modificatio of the DNA

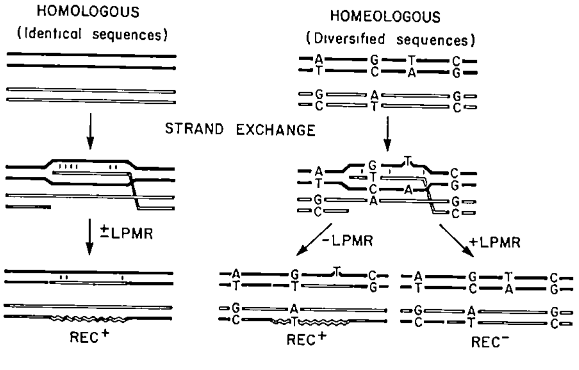

FIG 3 Molecular model for selective anti-recombination by LPMR (long-patch mismatch repair) proteins Homologous (identical) sequences recombine with the same efficiency in the presence or absence of active LPMR proteins (Table 4, and ref 9) Homeologous (diversified) sequences start to recombine by forming an heteroduplex containing mismatches caused by sequence differences in the two parental DNAs If LPMR proteins are not functional, homeologous recombination proceeds to form recombinant products (REC$^+$ phenotype) If LPMR proteins are functional mismatches in the heteroduplex regions are recognized, the reaction is reversed by the removal or destruction of the heteroduplex intermediate, and no viable recombinants arise (REC$^-$ phenotype) Although irrelevant to the mechanism of anti-recombination, the initiation of strand exchange is arbitrarily shown in a single-strand invasion mode[63] Only base-pair differences between the parental molecules are indicated the hybrid region in this sketch (shown with dashes indicating hydrogen bonding) contains one G T mismatch plus one unpaired T residue (as in a frameshift mutation)

Evidence for heterospecific gene replacement is shown in Table 4B The *hisD* allele in the recipient contains a Tn*10* derivative that confers chloramphenicol resistance Only 1 of 18 *hisD*$^+$ transductants retained chloramphenicol resistance All of 400 *proA*$^+$*B*$^+$ transductants retained chloramphenicol resistance A Mu*d-lacZ* fusion to *hisD* is likewise replaced during heterospecific recombination by P22 transduction (data not shown) Because the homospecific recombination by P22 ransduction occurs by integration of double-stranded DNA[36], he *mutH* effect in our experiments could have been due to repair synthesis generating new undermethylated DNA in *cis* o the incoming DNA

Discussion

The results reported here indicate that the suppression of mismatch repair can allow interspecies recombination between sequences that have as much as 20% sequence divergence Evidence for an inhibitory action of the *E coli* mismatch repair system on recombination between diverged sequences has been found in three other experimental systems First, by using a very short patch (vsp) mismatch repair system as a means to measure the formation of heteroduplex DNA intermediates *in vivo* it was found that the *mutH-mutU* system suppresses recombinant formation in bacteriophage λ crosses owing to the presence of two genetic markers[14] Second, carrying out crosses between a phage-λ vector and a plasmid, each bearing a mouse *V*H immunoglobin gene sequence, in a *mutS* host was found to increase recombination between partially homologous, but not between identical, *V*H genes[15] Finally, Karimova *et al* presented evidence indicating that recombination between two highly diverged lambdoid prophages can be enhanced in mutator hosts[10]

We favour proposals in which recombination between partially homologous sequences involves a reversible heteroduplex intermediate that is detected and aborted through a process that involves mismatch recognition[8,9] (see Fig 3) This is the stage at which genetic recombination is limited in transformation of *S pneumoniae* by the Hex mismatch repair system[16 17] The alternative proposal involves the mismatch-stimulated killing[11-13] of the products of recombination between diverged sequences[10 15] Although the mechanism by which mismatch repair proteins act to suppress recombination has not been elucidated, it seems that they edit not only the products of DNA replication[20-22], but also intermediates in the process of genetic recombination

There is evidence that mismatch repair also operates in fungal[37], amphibian[38] and mammalian[39] cells The average sequence divergence among individual copies of the major dispersed repetitive sequence families in mammalian genomes, such as the *Alu* sequences[40], is similar to the sequence divergence between the genomes of *E coli* and *S typhimurium* The mismatch repair system could act to prevent inter- and intrachromosomal rearrangements by suppressing recombination between misaligned dispersed repetitive sequences and thus play an important part in maintaining gene order in bacteria[41] and in eukaryotes Similarly, if the recombination suppressing effect of diverged sequences extends into neighbouring regions of perfect homology, then the high sequence polymorphism among homologous chromosomes in humans[42] could contribute to the suppression of mitotic recombination without compromising the ability of the cells to use recombinational DNA repair involving exchanges between sister chromatids of identical sequences (sister chromatid exchange) Mitotic recombination leads to the expression of deleterious recessive mutations which are often associated with pathological states such as cancer[43]

Some regulation of the mismatch repair system, or of the extent of heteroduplex DNA formation, would presumably be necessary during meiosis to allow pairing and recombination between homologues in spite of their sequence polymorphism If meiosis becomes deficient in chromosome pairing, for example, when sequence divergence is sufficiently extensive and a mismatch repair system is sufficiently active, chromosome nondisjunction will result in sterility[44] Fertility can then be restored through inbreeding or selfing, thus avoiding sequence divergence, or by transiently inactivating the mismatch repair system[45,46] The result would be the emergence of a new species Thus, mismatch repair could be a molecular mechanism for maintaining a genetic barrier between species that have diverged, but not drastically, on the DNA sequence level, and could accomplish the genetic separation (that is, reproductive isolation) required for evolution of species in the absence of geographical isolation[47] The acquisition of dispersed noncoding DNA, such as repetitive sequences and introns, could accelerate speciation by allowing an increased rate of genomic sequence divergence and subsequent meiotic and mitotic recombinational isolation of genes, chromosomes and species An alternative chromosomal mechanism for speciation is the accumulation of large chromosomal rearrangements An extensive study of a marsh rat population showed that chromosomal rearrangements, however, have a smaller role in reproductive isolation than that previously believed[48]

Mismatch repair apparently helps to prevent all classes of genetic alterations, it prevents point mutations by correcting replication errors[16 20-22] and chromosomal rearrangements by preventing recombination between sequences of only limited homology (limited in size[41] or extent—this work and ref 15) Modulation of the mismatch repair system[45 46] provides an effective way to control the rate of 'vertical' evolution (occurring by means of new point mutations and intrachromosomal rearrangements) and 'horizontal' evolution (occurring through recombination with diverged sequences)

This work shows that suppression of mismatch repair allows interspecies recombination between bacteria that have been diverging for ~150 million years[19] Hybrids were formed between *E coli* and *S typhimurium* that are in fact new species with only partial fertility in crosses with each of two parental

To determine co-inheritance of markers, *xyl*$^+$ or *met*$^+$ recombinants were replicated on media selecting for *met*$^+$ or *xyl*$^+$ bacteria, respectively, and scored after 2 days of incubation Total numbers of colonies analysed are given in parentheses The stability of *xyl*$^+$ recombinants was tested by growing each colony in a rich liquid medium and streaking on 1% xylose McConkey agar, on which *xyl*$^+$ bacteria give red colonies and *xyl*$^-$ bacteria white colonies For each recombinant, a red colony was grown and streaked a second time The recombinants that then gave only red colonies were scored as stable, whereas those giving some white, dark red or sectored colonies were scored as unstable Numbers are of recombinants scored Transposon loss was tested by replicating each of the recombinants previously scored for stability onto a rich medium containing tetracycline (12 5 μg ml^{-1}) for Tn*10* or kanamycin (50 μg ml^{-1}) for Tn*5*, and scoring resistant colonies after one day of incubation The first and second fractions represent the number of stable and unstable recombinants, respectively, expressing drug sensitivity All recombinants that lost the original Tn*10* or Tn*5* were shown in subsequent tests to have also lost the mutator phenotype (data not shown)

* An *arg*$^+$ marker used instead of *met*$^+$, the two are closely linked

	His, Arg, Cam	Pro$^+$, Cam^r	1,110

In part A, the recipient for P22 transduction was *hisD984* IS*200 proAB47* where *hisD* IS*200* is a nonreverting transposable element insertion[33] and *proAB47* is a nonreverting deletion of genes essential for proline prototrophy[59] The donor P22 Hft *int3* lysate[60] carrying *E coli hisD* sequences and *S typhimurium proAB* sequences was grown on strain TR5360 from John Roth's strain collection, although strain TR5360 contains *his*646, a deletion covering the *hisD* gene[35], it is a histidinol prototroph because it also carries *E coli* F′ 150 which includes the entire *E coli his* operon[61] All *S typhimurium* strains are in the LT2 background, although the *proAB*47 allele was first isolated in LT7 and subsequently moved into LT2 The P22 donor lysate with *S typhimurium* sequences at both the *his* and the *pro* loci was prepared on LT2 No 1 and 2 refer to two independent *mut*(*H, L, S* or *U*) derivatives of the initial recipient strain, these were obtained by P22-mediated transduction (as in Table 1) of mutator alleles from SL4213 *mut* strains (Table 1) Selection was conducted by spreading 0 1 ml of donor lysate and 0 1 ml of a fresh overnight culture of recipient cells on a minimal-glucose plate, the plates were scored after 2–3 days at 37 °C Aliquots of the same overnight culture and P22 donor lysate were used for both the histidinol (His$^+$) and the proline (Pro$^+$) selections When His$^+$ was selected, the plates contained proline and histidinol, for Pro$^+$ selection, the plates contained both histidine and arginine, the arginine prevents *argD* mutants from acting as indirect suppressors of proline auxotrophy[62] In part B, the recipient was *proAB47 hisD* Tn*10d-Cam* (which confers chloramphenicol resistance as well as histidinol auxotrophy[34]) *E coli* sequences donated *hisD*$^+$ and *S typhimurium* sequences donated *proAB*$^+$ Transductions were conducted as for part A Undiluted donor lysate (0 1 ml) was used for transductions to histidinol prototrophy and 0 1 ml of a 10-fold dilution of the lysate was used for transductions to proline prototrophy The numbers in the last column are the means of independent experiments, ranges were less than twofold Precise and nearly precise excision of transposons are increased in mutator backgrounds[41] but the insertion alleles used here are not susceptible to mutator-enhanced excision generating prototrophs neither the *hisD984* IS*200* nor the Tn*10d-Cam* allele reverted, even in mutator backgrounds (data not shown) Cam, chloramphenicol, Cam^r, chloramphenicol-resistant phenotype, Hol, histidinol

organisms The utility of technologies allowing interspecies recombination is wide ranging For example, attenuating the pathogenicity of *Salmonella, Shigella* or other pathogenic species by substituting appropriate genomic sequences from related nonpathogens (such as *E coli*) could allow the production o hybrid species suitable for live vaccines Interspecies transfe of interesting alleles should facilitate genetic analysis of relate species Easy selection for gene replacements, duplications an amplifications after conjugation could provide useful micro-organisms in which the duplicated heterospecific region is stabilized by converting recombinants to *mut*′ (Table 3) In addition interspecies genetics could facilitate studies on the structure and function of hybrid operons (Table 4), genes and proteins[5] and the production of proteins with altered activity, stability or specificity For example, recombination between diverged genes in *mutL, S* bacteria should create complex heteroduplex regions which are substrates for diverse specialized vsp mismatch repair systems (see ref 9 for a review) generating complex patchworks of the two parental sequences[49] By recombining and patchworking functionally equivalent but sequence-diverged genes cloned from different species, it should be possible to create new diversified genes that still conserve their basic motif and yet alter stability or specificity of the gene products This strategy for protein 'engineering' could be similar to hyperconversion mechanisms generating diversity in the expressed genes by their recombination with diverged silent (pseudo)genes (see ref 50 for a review), as in the case of immunoglobin genes[51] and genes coding for variable surface proteins in parasites[52,53] □

Extragalactic radiation and the ultra-high-energy cosmic-ray spectrum

F. W. Stecker

Laboratory for High Energy Astrophysics,
NASA Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

The high-frequency (submillimetre) side of the 'black-body' radiation spectrum has now become available for study from balloons and the soon-to-be-launched Cosmic Background Explorer (COBE) satellite There is recent evidence of an unexpectedly large excess of radiation beyond the peak of the black-body curve[1], which seems to be generally isotropic[2] and therefore of extragalactic extent. Such radiation will have a significant effect on the propagation of ultra-high-energy cosmic rays. Because of the importance of this new discovery and the timeliness of the subject, I re-examine here the effect of extragalactic microwave and submillimetre-radiation fields on the ultra-high-energy cosmic-ray spectrum. Although the most detailed work[3,4] so far is based on complex numerical simulations of individual interactions, I find that the general characteristics of the spectrum can be derived from fairly simple analytical arguments I show that one can explore, by simpler and more general means, the various spectral features obtained by numerical calculations ('pile-up' bumps and 'dips'[3,4]). I illustrate this technique with a newly derived lifetime–energy relation, based on the new submillimetre observations.

Semi-analytical methods can be useful in examining the implications of forthcoming data on background radiation fields without computer simulations involving specific parameterizations Such features can be obtained directly from a consideration of the average lifetime curves[5-7] and the phase-space continuity equation For simplicity, I consider that the highest-energy cosmic rays are protons (Similar considerations can be extended to nuclei, but that case is complicated by a time-variable charge-dependent pair-production loss rate owing to the photodisintegration process[3]) The effective lifetime of such cosmic rays against energy loss by photomeson production (or equivalent mean-free-path) on black-body radiation of temperature, T_{B}, is given by[5]

$$\tau^{-1}(E)=(1/4\pi)\gamma^2h^3c^2\int_{\varepsilon_{\mathrm{th}}/2\gamma}^{\infty}\mathrm{d}\varepsilon(\exp(\varepsilon/kT_{\mathrm{B}})-1)$$

$$\times\int_{\varepsilon'_{\mathrm{th}}}^{2\gamma\varepsilon}\mathrm{d}\varepsilon'\,\sigma_{\gamma\mathrm{p}}(\varepsilon')K(\varepsilon') \qquad (1)$$

where γ is the proton Lorentz factor, ε' is the photon energy in the rest frame of the ultra-high-energy proton and the inelasticity, $K(\varepsilon')$, is the mean energy lost by photomeson production per interaction

Equation (1) for a pure black-body spectrum can easily be extended to include the recently discovered submillimetre-radiation field by using the parameterization of a pure black-body field and a further submillimetre gray-body radiation field[8] of temperature $T_{\mathrm{G}} = 4\ 9$ K and dilution factor 0 04 The cross-section data originally used in ref 5 have been updated using recent compilations of the Particle Data Group[9] Pair-production losses[5] have also been included to obtain the total lifetime curve Figure 1 shows the function $\tau(E)/E$, which is the inverse energy loss rate in GeV^{-1} s The solid curve includes the effect of the submillimetre radiation and the dashed curve indicates the effect of the black-body radiation field only

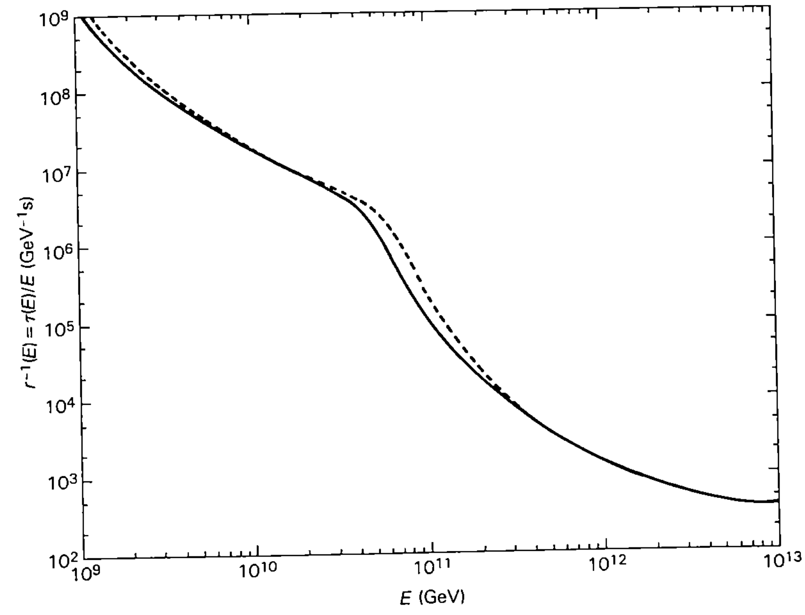

FIG 1 The inverse energy loss rate $r^{-1}(E)$ produced by the black-body radiation field only (dashed line) and the black-body radiation field plus the submillimetre radiation field (solid line)

I note that the mean lifetime curve itself (which can be obtained from Fig 1) is the source of much information First, it indicates that if the sources of ultra-high-energy cosmic rays are of cosmological origin, from quasars or primordial galaxies for example, protons of energies larger than $\sim 10^{10}$ GeV will be degraded by energy losses from pair production and photomeson production[10 11] Second, protons in the energy range $\gtrsim 10^{11}$ GeV should have a 'local' origin, most likely from sources within the local Virgo Supercluster, if the spectrum shows no attenuation effects at the highest energies[5] The local-supercluster-origin model first suggested in ref 5 has been developed elsewhere[12,13]

Figure 1 can be used as a starting point for a further examination of the spectral features to be expected, given an ultra-high-energy cosmic-ray source function $q(E, t)$ The quantity $\tau(E)$ defined in equation (1) should not be misinterpreted It represents a characteristic energy loss time for the protons, not a decay time for catastrophic loss In fact, because of the inclusion of the integration over the inelasticity term $K(\varepsilon')$, $\tau(E)$ can be rewritten so that a simple formalism that automatically conserves proton number can be used To do this, I first define a function describing the mean energy loss rate from pair production and photomeson production interactions, $r(E) \equiv \mathrm{d}E/\mathrm{d}t$ so that

$$r(E) = E/\tau(E) \qquad (2)$$

and the quantity τ/E plotted in Fig 1 is actually the inverse of the mean proton energy loss rate Conservation of proton number is then assured by the relation

$$\frac{\partial n(E, t)}{\partial t} + \frac{\partial}{\partial E}[n(E, t)r(E)] = q(E, t) \qquad (3)$$

which describes a divergenceless flow of cosmic-ray protons in energy space in the case for which I assume spatial isotropy and no catastrophic losses In this case, the cosmic-ray flux is directly proportional to the proton number density

$$I(E, t) = n(E, t)c/4\pi \qquad (4)$$

Equations (3) and (4) have the solution[14]

$$I(E, t) = \frac{\tau(E)c}{4\pi E}\int_E^\infty \mathrm{d}E'\, q\left(E', t - \int_E^{E'} \frac{dE''}{E''}\tau(E'')\right) \qquad (5)$$

In equation (5), the quantity $\tau(E)/E$ has been substituted for the inverse of the absolute value of the energy loss rate, as follows from equation (2) Equation (5), which was obtained using Green's function techniques, clearly indicates that the cosmic-ray spectrum at time t is obtained from two factors These are a term that is the inverse of the energy loss rate at energy E, which accounts for the 'trickle out' to energies below E and is the factor given in Fig 1, and a 'trickle down' input factor given by the integral over source spactra from earlier times

$$t' = t - \int_E^{E'} \frac{\mathrm{d}E''}{E''}\tau(E'') \qquad (6$$

and higher energies $E' > E$, for which the initial energies have been degraded by energy losses For example, it follows from the the results in Fig 1 that it takes $\sim 10^9$ yr for a $\sim 10^{11}$ GeV proton to be degraded to an energy of $\sim 4 \times 10^{10}$ GeV It is the effect of the 'trickle down' integral that can cause a 'pile-up' in the spectrum

The treatment I use here breaks down at energies $\lesssim 10^9$ GeV, the point at which the energy loss time becomes comparable to or greater than the Hubble time For cosmic rays of truly cosmological origin, the age of which is a significant fraction of the age of the Universe, energy losses and dilution effects from the expansion of the Universe have a critical role In this case, the first term in equation (3) must be replaced by a derivative with respect to redshift[7,14] I will not pursue the subject of the cosmological cosmic rays here as it is beyond the scope of this paper and does not seem to bear on the origin of the highest-energy cosmic rays[5]

As illustrations of how this formalism can be used, I consider a steady-state solution of equation (3), and a 'burst' delta-function source spectrum that has been 'aged' by a specific amount (refs 3, 4)

To find the steady-state time-independent solution, I set the $\partial n/\partial t$ term in equation (3) equal to zero Equation (5) then becomes

$$I(E) = \frac{\tau(E)}{E}\int_E^\infty \mathrm{d}E'\, q(E') \qquad (7)$$

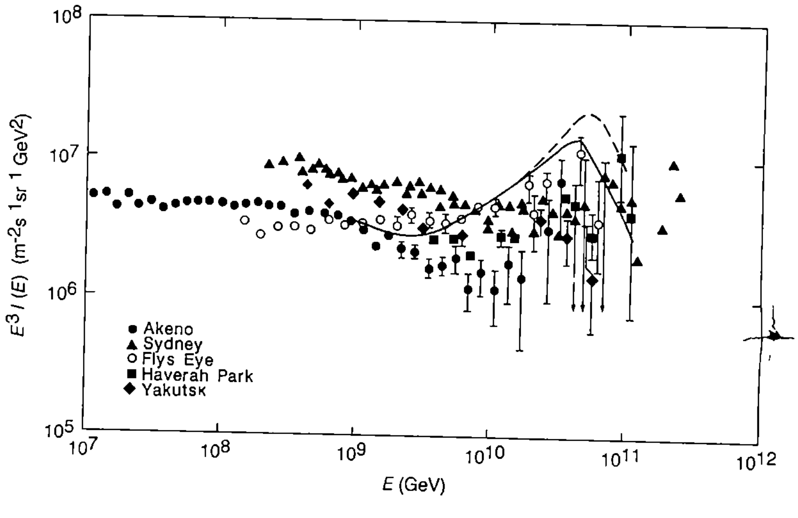
which can be integrated if $q(E)$ is a power-law spectrum $KE^{-\Gamma}$ In this case

$$I(E) = \frac{q(E)\tau(E)}{\Gamma - 1} \qquad (8)$$

Thus, the factor $\tau(E)$ has the role of a modulation factor on the initial source spectrum It is as if the cosmic rays of energy E were built up over a time given by $\tau(E)/(\Gamma - 1)$ The flux at energy E becomes proportional to the energy loss time at energy E as well as the source flux at energy E

Figure 2 shows the form of the spectrum obtained by an application of equation (8) in the case of an E^{-2} source spectrum such as might be expected if the highest-energy cosmic rays are produced by shock acceleration in extragalactic sources[15] The spectrum is superimposed on a compilation of recent air-shower data[16-20] A 'pile-up' effect between 2 and 5×10^{10} GeV can

FIG 2 The cosmic-ray flux spectrum derived from various air-shower results shown with the shape of the steady-state equilibrium spectrum obtained from equation (8) (Solid and dashed lines as in Fig 1)



seeing was ~1 5 arcsec in diameter Although the broad component, which is due to the supernova itself, originated in an unresolved point source, approximately half of the total intensity of the narrow component arose in a compact source or 'knot' displayed by 0 8 ± 0 3 arcsec at position angle 200 ± 15° The knot diameter was ≤1 5 arcsec (1 2 light yr) A faint northerly extension to the emission was also seen We also made north–south line scans through supernova 1987A, using the same spectral and spatial sampling, and a similar displacement in declination was seen (Fig 3) Clearly, most of the emission in the narrow component had a circumstellar origin

Several observations indicate that the compact source lay behind the supernova, and so had been observable for less than the supernova lifetime First, circumstellar gas at the source position angle is receding[8] Second, contemporary mid-infrared measurements (P F Roche, D K Aitken and C H Smith, personal communication) revealed supernova-illuminated dust lying in a compact region displaced from the supernova and, to within the errors, coincident with the He I knot Because dust cools virtually instantaneously, its emission maps out the present location of energy from the light-curve peak Considerations of geometry, light travel time and temperature indicate that the dust must lie behind the supernova[20,21] Third, direct optical continuum imaging around day 750 indicates scattering from dust with a region of enhanced surface brightness at about the same sky position as the He I knot[17] Geometry and light-travel-time effects again point to a location behind the supernova Optical speckle observations[22] in a continuum bandpass also show a source at about the same position from days 644 to 697, although there seems to be some disagreement between direct and speckle imaging as to the position and magnitude of the brightest region[17,23 24] Fourth, the high density derived below shows that the source did not comprise the material emitting the ultraviolet lines during the first 1 1 years

We have constructed a simple model of the compact He I source consisting of a slowly moving cloud of hydrogen and helium only We assume that it was fully ionized by the ultraviolet flash, and that light travel time across it was unimportant Our model predicts almost constant He I 1,083-nm emission per unit volume from 3 months to 1 year after initial ionization From the constancy of the observed intensity we conclude tha the mass of emitting gas did not increase significantly durin the period of observation, so that by day 737, we had bee viewing the same cloud for at least 0 8 yr If we adopt a viewi time of 1 yr since ionization, the cloud lies 0 8 light yr from t supernova

We have allowed for recombination, collisional effects an ionization of neutral atoms by photons released in the recombination of He^{2+} We take the He I line to be optically thin an use atomic parameters from refs 25–30 An electron temperatur of ~25,000 K was inferred from approximately contemporar intensity ratios of the narrow 436 3, 495 9 and 500 7-nm [O III lines (R Stathakis, personal communication) A higher temperature was found initially[34], but cooling would have bee rapid[11] Only some of the [O III] emission had the same sk position as the knot[17], and so we do not know if the [O III] derived temperature is appropriate for the helium cloud W therefore adopted 30,000 K as a conservative upper limit for th cloud temperature—a lower temperature would increase th inferred helium overabundance Our only free parameters wer the electron density N_e and the helium mass fraction Y W corrected for interstellar reddening[32,33] and included contributions of He II to the Balmer lines

We have compared the model with our He I observations an with the intensities of narrow Hα, Hβ and He II 469-nm line obtained from A P S Crotts (personal communication) an from the Anglo-Australian Observatory supernova archive (R Stathakis, personal communication) Around day 750, the tota narrow Hα intensity from the region within 3 arcsec of t supernova was 9×10^{-13} erg cm^{-2} s^{-1} The total narrow H intensity was 0 3 of this The He II 469-nm intensity decrease by about a factor of four between days 613 and 756 and ha approximately one-third of the total Hβ intensity on day 756 These intensities are un-dereddened

From images obtained around day 750, it is estimated (A P S Crotts, personal communication) that 0 3 ± 0 1 of the narrow Hα flux came from within the 1 5-arcsec maximum extent of the He I knot In comparing the model and observations, we therefore made the conservative assumption that 0 3 of the hydrogen emission originated from the cloud For $T = 30,000$ K,

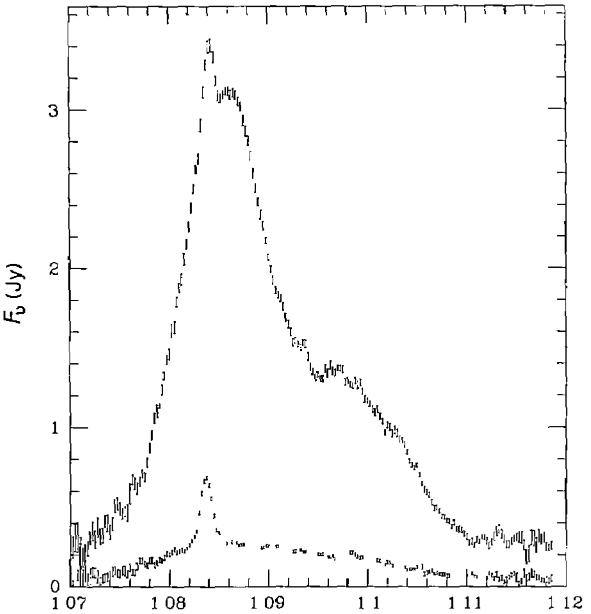


FIG 1 Spectra of supernova 1987A taken in September 1988 and January 1989 The broad component is helium and hydrogen emission from the supernova ejecta The narrow component is helium in the circumstellar shell

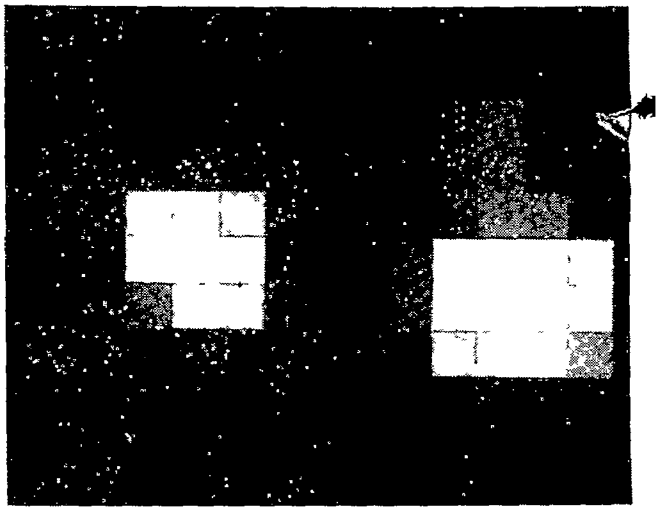

FIG 2 Grey-scale representations of maps of the broad (left) and narrow (right) components seen in Fig 1 North is at the top and east to the left The focal plane was sampled on a square grid, with 0 7-arcsec pixels, through a 1 4-arcsec square aperture The contribution of the broad component was removed from the observed flux in the narrow component by scaling from a fully sampled spectrum The resulting image shows the distribution of the narrow component alone Both maps have been automatically scaled to cover the full tonal range

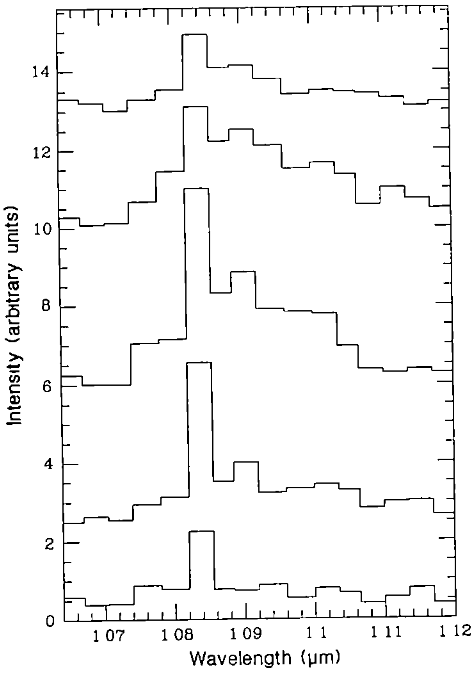

FIG 3 Six undersampled spectra from ~200 co-added declination scans through supernova 1987A, taken at 0 7-arcsec spacing The narrow component peaks in the second and third spectra from the bottom (south), and the broad component in the third and fourth

the model satisfactorily reproduces the observed fluxes if $N_e = 10^5$ cm^{-3} and Y is in the range 0 4-0 5 The corresponding N(H) is also $\sim 10^5$ cm^{-3} The 1,083-nm He I line arises both directly by recombination of ionized helium and from collisional excitation of the metastable 2^3S level. At $N_e \sim 10^5$, the latter dominates and the line is strengthened relative to the recombination case by more than an order of magnitude[25] The cloud mass density is about 10 times larger than the typical value for the whole shell obtained from ultraviolet observations[6] From the He I line intensity we derive a total mass of $\sim$0 01 $M_\odot$ in the cloud This is a factor of 5-10 less than the shell mass inferred from the ultraviolet lines[6,11]

In the plane of the sky the shell extended to ~2 light yr from the supernova[16,17,31] and had lower density[6] The cloud could not have been produced by the second (blue supergiant) wind, for if it had expanded into an isotropic shell it could only have accumulated high densities at larger radii The compact He I source may be an interstellar cloud that successfuly resisted the momentum flux of the red-supergiant wind However, it is unlikely that an interstellar cloud with so high a helium abundance would lie within 1 light yr of the supernova An alternative is a bipolar red supergiant wind[16], possibly also interacting with the interstellar medium A symmetrical bipolar form is incompatible with our data because the frontal lobe would now be seen at age 2 yr, yielding a 1,083-nm intensity 60% that of the rear lobe Moreover, any such frontal lobe must have been less dense than the rear if the density is to be compatible with the ultraviolet line ratios We therefore interpret the cloud as part of an asymmetric red-supergiant outflow An interacting outflow behind the supernova may account for the extended mid-infrared and continuum optical emission[17,20] Crotts *et al*[17] suggest that the circumstellar shell is near a dense flat sheet, possibly of interstellar origin, lying behind the supernova and point out that the He I knot lies close to where the shell and sheet intersect

Extensive mass loss and mixing of the progenitor envelope have been invoked to account for its blue-red-blue evolution before explosion and to explain the high N/C and N/O ratios inferred from the ultraviolet data[1-3] With the further constraint that the progenitor envelope was massive, Saio *et al*[2] find that complete mixing of the hydrogen-rich envelope together with dredge-up of about one solar mass of material from the helium core is required, giving a surface helium abundance ~0 45 Our observations support this model

Finally we note that the cloud subtends up to 2 sr at the supernova so the total number of photons capable of doubly ionizing helium and radiated isotropically in the ultraviolet flash must have been at least 10^{55}, in agreement with model predictions and ultraviolet observations[9-11] ☐

Photoisomerization of OClO: a possible mechanism for polar ozone depletion

CONNECTIONS between polar ozone depletion and halocarbon chemistry have been established by a number of studies[1-10] Recent attempts to account quantitatively for the observed rate of ozone decline in Antarctica in terms of known photochemical processes have not been entirely successful, and it seems that further chemical ozone-depleting mechanisms may be needed, particularly if the transport of ozone into the polar regions competes with chemical losses. Spectroscopic and photochemical data indicate that photolysis of OClO may provide a further ozone loss mechanism that has not previously been considered Here we report laboratory studies of OClO spectroscopy and photoproducts which suggest

that atomic Cl and O_2 are formed to some extent in the photodissociation process. This evidence points towards possible photoisomerization to the unstable species ClOO, (or at least to a similar metastable intermediate) probably by way of the ${}^2B_2$ excited state of OClO, thus reinforcing the idea that photolysis of OClO may contribute to polar ozone depletion

The discovery by Farman *et al*[1] in 1985 that a precipitous drop in Antarctic ozone had occurred has been the impetus for intensive studies of the Antarctic stratosphere Those studies quickly established that the Antarctic ozone decline occurs largely in September[2-4] when the total column of Antarctic ozone drops by ~50% as compared with historical values obtained in the 1960s A number of workers suggested that the decline in ozone might be related to increasing chlorofluorocarbon abundances[1], and noted that the unique depletion in the Antarctic spring could result from the combination of extremely cold temperatures which produce polar stratospheric clouds (PSCs), and the presence of sunlight to drive photochemical processes[5-7] Detailed studies of the stratospheric composition during September (in 1987, in particular) revealed that the chemistry of the Antarctic stratosphere had been greatly perturbed, leading to large abundances of chlorine radicals that can destroy ozone quite readily in the sunlit atmosphere[8,9] These studies provided firm links between the ozone loss and halocarbon chemistry

Although it is clear that the highly unusual chlorine chemistry induced by heterogeneous reactions occurring on the surfaces of polar stratospheric clouds can account for a substantial fraction of the ozone loss, it is difficult to be more quantitative because of uncertainties in both the laboratory and field measurements A number of catalytic cycles involving chlorine monoxide radicals participate in the chemical destruction of ozone in the sunlit Antarctic stratosphere Recent studies[8-11] are in general agreement that formation and photolysis of the ClO dimer is the dominant mechanism for Antarctic ozone destruction, at least during 1987 Coupling between chlorine and bromine represents a second important ozone loss pathway, the rate limiting step of which is

$$\mathrm{ClO + BrO \rightarrow Br + ClOO} \qquad (1)$$

Although reactions involving the ClO dimer are likely to dominate ozone loss in Antarctica under cold conditions and when ClO abundances are high, the bromine-chlorine mechanism assumes greater importance at warmer temperatures or when ClO enhancements are modest It is therefore likely to play a major and possibly dominant role in Arctic ozone loss, but also contributes ~20-30% of the Antarctic ozone depletion according to present understanding Barrett *et al*[8] suggested that the formation and photolysis of the ClO dimer could explain virtually all of the observed Antarctic ozone loss in 1987 based on their measurements of chlorine monoxide, but recent measurements for the reaction rate constant of ClO with itself to form the dimer (Cl_2O_2) have reduced the apparent importance of this mechanism There is now considerable question as to whether or not currently understood chemical mechanisms can explain the observed rate of Antarctic ozone loss[9-11] One study[9] estimated that only 65% of the total observed Antarctic ozone loss rate could be accounted for through the photochemistry suggested to date, whereas others conclude that the photochemic loss may be sufficient to account for the entire ozone decline

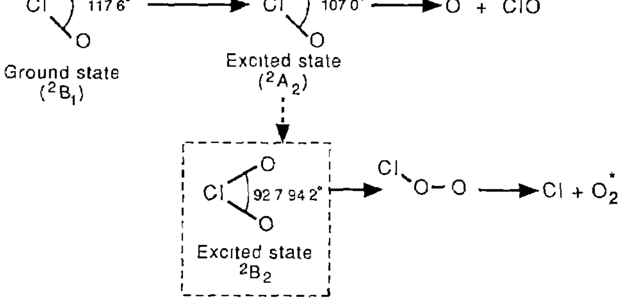

FIG 1 Schematic diagram of the suggested photochemistry of OClO

Many studies have implicitly or explicitly assumed that the Antarctic vortex acts entirely as a 'containment vessel' in which chemistry takes place in total isolation Any downward or poleward transport of ozone into the depleted region will probably require considerable increases in the rate of chemical destruction to account fully for the observed ozone decrease[12,13]

The interest in polar ozone has led to a fuller understanding of many of the chemical mechanisms that occur in the lowest part of the stratosphere In spite of this rapid progress, it seems likely that other unidentified chemical processes could contribute to the ozone decline In particular, it is widely accepted that a second product channel of the reaction between ClO and BrO leads to formation of OClO

$$\mathrm{ClO + BrO \rightarrow OClO + Br} \qquad (2)$$

This process is not expected to account for a net ozone loss, as rapid gas-phase photolysis of OClO has hitherto been assumed to produce exclusively atomic oxygen, which will reform ozone by the reaction with molecular oxygen

$$\mathrm{OClO} + h\nu \rightarrow \mathrm{ClO} + \mathrm{O}(^3\mathrm{P}) \qquad (3)$$

Note the contrast between the chemistry of OClO, which is thermally stable, and its isomer, ClOO, which is extremel unstable

If photolysis of OClO were to involve the following two-step process

$$\mathrm{OClO} + h\nu \rightarrow \mathrm{ClOO}\ \text{(photoisomerization)} \qquad (4)$$

$$\mathrm{ClOO + M \rightarrow Cl + O_2 + M} \qquad (5)$$

then formation of OClO would be a chemical pathway to ozone destruction If all OClO photolysis were to proceeed through photoisomerization, then the ozone loss rate that is due to the coupling of chlorine and bromine would roughly double (as the rate constants for reactions (1) and (2) are believed to be comparable at cold temperatures) Given the extremely labile nature of ClOO, it is expected to be very short lived and, probably cannot be observed directly following the photolysis of OClO in the gas phase However, the final outcome of the near-ultraviolet photolysis of OClO by reactions (4) and (5), namely formation of O_2 and Cl, is measurable in the laboratory and of importance in connecting OClO to the stratospheric ozone depletion Here we show that laboratory evidence indicates that OClO near-ultraviolet photolysis involves just such a photoisomerization mechanism We also discuss the spectroscopic and photochemical data available regarding the possible role of photoisomerization in the photochemistry of OClO

The spectroscopic information available can be used to obtain accurate excited-state structures and establish the compatibility of the proposed photochemistry with the observed changes in bond length and bond angle that occur on excitation Specifically, activity in the asymmetric bond stretch (ν_3 in the OClO spectrum) is needed to break a Cl-O bond Conversely, a decreased bond angle reflected in activity in the bending mode (ν_2) in the excited state, provides the geometry change required for photoisomerization

The near-ultraviolet spectrum of OClO extends from 21,000 to 37,000 cm^{-1} (270-476 nm), the observed features being attributed to a transition from the ${}^2B_1$ ground state to ${}^2A_2$ excited electronic state[14-16] In this transition[16 17], the Cl-O bond length increases from 1 47 Å in the ${}^2B_1$ state to 1 619 Å in the ${}^2A_2$ excited state, and the bond angle decreases substantially from 117 6° (${}^2B_1$) to 107 0° (${}^2A_2$) as shown in Fig 1

The excited-state structure and vibronic lifetimes are significantly perturbed by the efficient photochemistry occurring on excitation of OClO in the near-ultraviolet The photoreactivity at this energy is presumed to be linked to coupling of the $^2A_2$ state with the symmetry-forbidden $^2B_2$ state[17-19] The latter has eluded direct spectroscopic observation, but is calculated[17] to have a minimum bond angle ranging from 94 2° to 92 7°, and consequently to favour photoisomerization[17] (see Fig 1)

In principle, examination of a structured spectrum such as that of OClO can provide the desired information on the excited state At room temperature, however, spectra are too congested for such an analysis because of the thermal populations of many ground-state rotational levels, all of which are involved in the electronic transition As a result, the vibronic linewidths are dominated by thermal effects that exceed the natural linewidths and therefore preclude obtaining the excited-state lifetime

We have re-examined the spectroscopy and photochemistry of OClO free of inhomogeneous effects[20] by preparing samples in supersonic molecular jets The jet-cooled A $(^2A_2) \leftarrow X(^2B_1)$ absorption spectrum of OClO has recently[20] been obtained in our laboratory with an apparatus that combines a high-resolution Fourier Transform ultraviolet spectrometer with a high-throughput molecular jet Figure 2 shows a portion of the spectrum resulting from the transition to the $^2A_2$ state of OClO In the absence of thermal effects, the Heisenberg uncertainty principle establishes an inverse relationship between vibronic linewidths and excited-state lifetimes Thus the cold spectrum allows dynamical information to be obtained We can draw two conclusions from our spectra First, all vibronic linewidths increase with energy The corresponding lifetimes decrease from ~100 ps at 23,000 cm^{-1} (~435 nm) to ~1 ps at 33,000 cm^{-1} (~303 nm), reflecting the timescale of photochemical events Second, comparing the lifetimes of the three vibronic modes of OClO at approximately the same energy indicates that both the asymmetric stretch and the bend are involved in the photoreactivity of this molecule excited in the near-ultraviolet As a consequence of photodissociation, the asymmetric stretch displays very short lifetimes even at low energy, the $\nu_3 = 4$ level, for example, becomes so broad that it disappears into the noise (having a linewidth of 100 cm^{-1} at ~30,000 cm^{-1}) At the same time, progressions involving the bending mode (ν_2) broaden substantially at approximately the same energy, supporting the conjecture that ν_2 is involved in coupling the $^2A_2$ to the $^2B_2$ state, which is expected (in light of the small bond angle[17]) to favour photoisomerization

In summary, the spectroscopic evidence is consistent with both photodissociation and photoisomerization occurring on the near-ultraviolet excited electronic surface

The photochemistry of OClO has been investigated extensively using flash photolysis and laser techniques[22-25] Most authors agree that OClO dissociates[19,21-24] into ClO and O (reaction (2)), but some[19,24] have suggested alternative pathways (reactions (4) and (5)), leading to Cl and O_2^* Here, O_2^* could be, on the basis of energy, the $a^1\Delta_g$, the $b^1\Sigma_g$ excited states or vibrationally hot levels of the ground state $^3\Sigma_g$ To date, the primary photochemistry of OClO remains controversial, as experimental studies are complicated by rapid secondary reactions that obscure the primary events

To elucidate the primary photochemistry of OClO in the gas phase, we are reinvestigating this problem by preparing the molecule free of collisions in supersonic expansions The detection is based on resonance-enhanced multiphoton ionization/mass spectrometry (REMPI/MS) We measure strong, wavelength-dependent ClO^+ and Cl^+ mass signals following OClO photolysis Molecular oxygen has an extremely low multiphoton ionization (MPI) cross-section[26], making it difficult to detect in our system The Cl^+ action spectrum appears between 360 and 363 nm It is likely that this signal reflects the coupling of OClO and ClOO, or the REMPI structure of the isomerized parent molecule, ClOO REMPI of other precursors such as OClO or ClO can be excluded Our interpretation implies photoisomerization of OClO, followed by dissociation to produce atomic chlorine which is then probed by the MPI process This finding is consistent with Gole's analysis that isomerization of OClO occurs by the $^2B_2$ state (ref 17), as seen in the matrix experiment of Arkell and Schwager, most efficiently at ~365 nm (ref 27) The relative yield of the neutral photolysis products ClO, O_2 and Cl cannot be obtained from the data at this stage because of the unknown and very different MPI cross-sections which govern the signals detected These results suggest, however, that excitation in the near-ultraviolet of isolated OClO in the gas phase leads to both photodissociation to form ClO and to photoisomerization which ultimately leads to formation of O_2 and Cl

The involvement of photoisomerization is compelling in light of the matrix photochemistry[17 27,28] of OClO Photolysis of the symmetric chlorine dioxide in the near-ultraviolet electronic state, in argon, nitrogen or sulphuric-acid matrices, leads exclusively to formation of ClOO Quantum chemical calculations[17] explored the nature of the isomerization process and a mechanism was proposed for the concerted conversion of OClO to ClOO Photoisomerization is expected[17] to occur by coupling of the $^2A_2$ state to the $^2B_2$ state, as already mentioned (see Fig 1) The efficiency of this photochemical process is governed by both the position of the curve crossing between the two electronic surfaces and the magnitude of the coupling between them

We suggest a new model for the near-ultraviolet primary photochemistry of OClO vapour that is consistent with all the spectroscopic and photochemical data We propose that two photochemical reactions take place, namely photodissociation and photoisomerization, as shown in Fig 1 This model can explain the differences between the gas and condensed-phase photochemistry as it proposes that the relative quantum yields for photodissociation and photosiomerization vary with energy

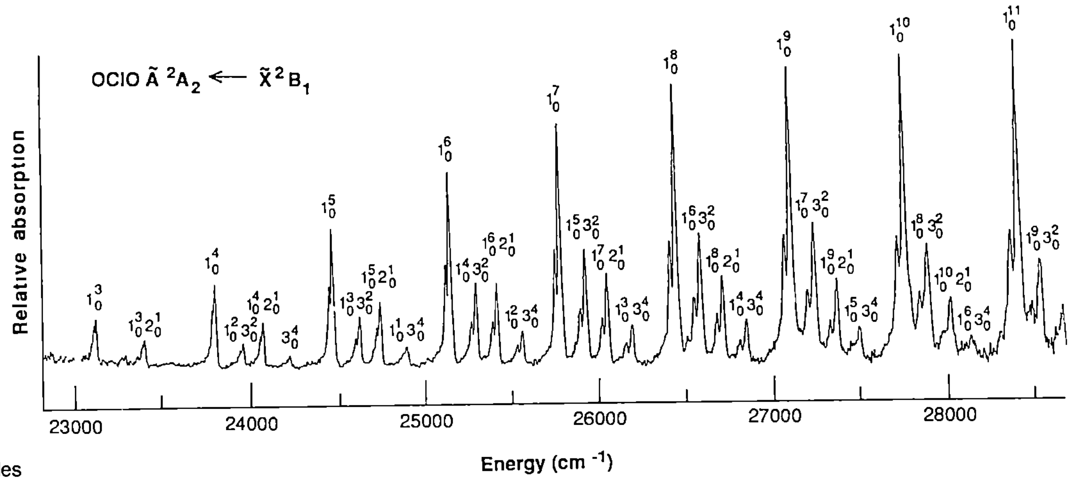

FIG 2 A portion of the jet-cooled absorption spectrum of the A←X transition of OClO, recorded at 5-cm^{-1} resolution under conditions of 3% OClO in He at a stagnation pressure of 2 atm The splitting in each band is caused by ^{35}Cl and ^{37}Cl isotopes All of the vibrational modes are observed in this spectrum The most intense progression has been assigned to excitation of the symmetric stretching mode (ν_1), whereas the less intense progressions involve the bending (ν_2) and the asymmetric stretching (ν_3) modes

Figure 1 shows the results from our measurements of axis ratio as a function of drop diameter d. For the smallest drops ($d \leq 1$ mm), our observations of axis ratios agree with the theoretical quiescent shape[7,9] within experimental uncertainty. The previous experimental data at small sizes[10] shows approximately the same scatter but seems to have a systematic error. In the present experiment, such errors were carefully evaluated and minimized using glass spheres to compare axis ratios obtained using the photographic method with those from direct measurements.

The measured axis ratios show a large two-sided scatter for $d \geq 1.4$ mm and a moderate one-sided scatter, above the theoretical curve, for $d \approx 1.0$–1.3 mm. The large two-sided scatter can be explained by axisymmetric mode oscillations of oblate- and prolate-like shapes having a two-sided axis-ratio variation, as Fig. 2 shows. Also, our measurements of the axes for the largest sizes revealed the characteristic opposing variation in v and h. The observed one-sided scatter for $d \approx 1.0$–1.3 mm is consistent with transverse-mode oscillations of the lowest harmonic. As Fig. 2 shows, the maximum vertical extent increases more than the maximum horizontal extent for various side views so that observations of v/h should yield a one-sided variation above the quiescent axis ratio.

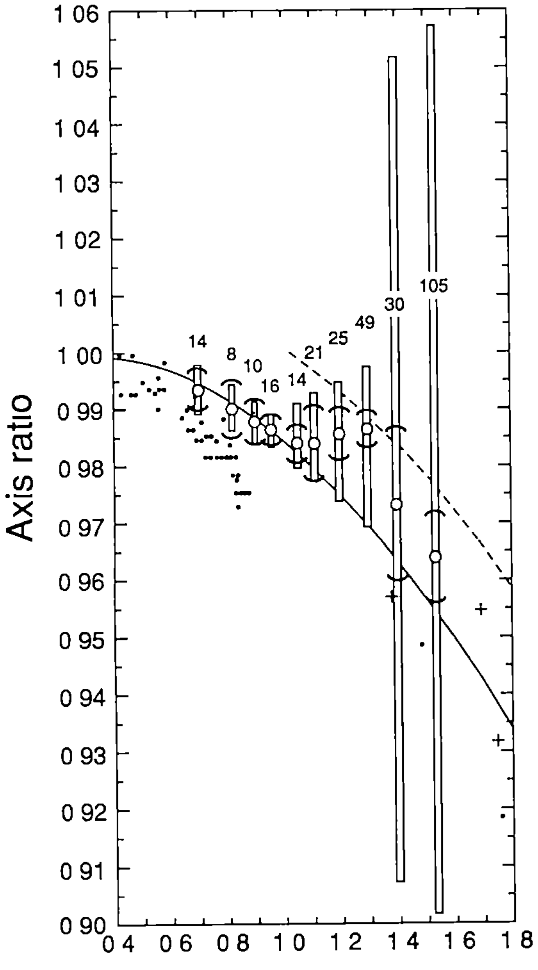

FIG. 1 Measured axis ratios as a function of drop diameter. The vertical bars show the range of measured values, including scatter and estimated (r.m.s.) experimental uncertainty. The uncertainty decreases with size at a fixed magnification because a measurement of axis ratio becomes more precise. Also displayed are mean axis ratios (circles), 95% confidence intervals (arcs) and number of measurements. The width of the bars indicates uncertainty from minor changes in drop size during (or between) experiments. About 4,000 photographs were needed to obtain 292 axis ratios, because of a preponderance of out-of-focus drops (horizontal scatter in fall trajectories was much larger than depth of field). The theoretical quiescent axis ratio is the solid curve[7-9] and previous wind-tunnel measurements are dots[10] and crosses[7]. The dashed curve shows the postulated shift in axis ratio based on polarization radar measurements in rain[6].

Further support for these postulated modes is the consistency of oscillation energies despite the different axis-ratio amplitudes in Fig. 1. Energies are comparable if the transverse mode is assumed for $d \approx 1.0$–1.3 mm and the axisymmetric mode is assumed for $d \geq 1.4$ mm (~0.2–0.4% of the surface energy). By contrast, energies differ by a factor of 20 if the reverse is assumed (axisymmetric mode at the smaller sizes and transverse mode at the larger sizes).

The onset of raindrop oscillations at $d \approx 1.0$ mm is close to the onset of eddy shedding for falling drops and spheres (Fig. 3). In addition, the observed onset of sideways drift also occurs just above $d = 1.0$ mm. For drops of $d = 1.0$–1.3 mm the match between oscillation and eddy frequencies is best at the lowest harmonic ($n = 2$). The two largest sizes have a better match with the two higher harmonics ($n = 3$ and 4). Although different harmonics have distinct shapes, it was difficult to distinguish among them from the drop photos because the single view of the profile could correspond to more than one mode, and the distortions were hard to identify at these small amplitudes.

Another distinguishing characteristic of each harmonic is its oscillation frequency, for example $n = 3$ has a frequency about twice that frequency of $n = 2$ (Fig. 3). Oscillation frequencies were measured by recording drop-fall streaks from a xenon light by using the modulation of the rainbow (Fig. 4). Large-amplitude oscillations produce dashed streaks in back-scattered light[14], as can be seen by shining a floodlight at rain or water dripping from a tree branch. Such streaks occur when the angle Ψ changes around the primary rainbow angle as light is deviated from the bow into the dark band. Our streak photos revealed dashes of spacing λ corresponding to the frequency of the fundamental harmonic f_2 ($f \approx f_2$), using the known terminal fall

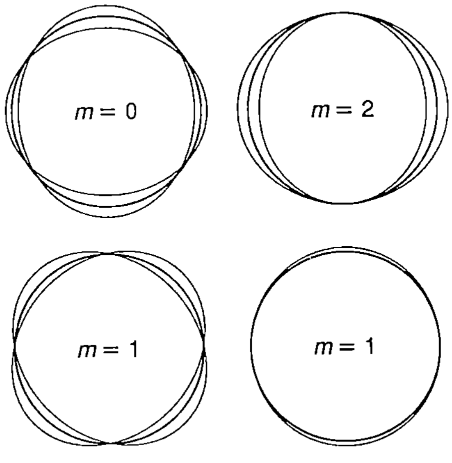

FIG. 2 Horizontal views (thin lines) for fundamental spherical harmonic ($n = 2$) and unperturbed spheres (thick lines). The three modes ($m = 0, 1, 2$) of equal oscillation energy (1% of surface energy) correspond to associated Legendre functions. The axisymmetric mode ($m = 0$) has oscillations of oblate- and prolate-like shapes with a two-sided axis-ratio variation about unity. The transverse mode ($m = 1$) is shown for two orientations (side views), 90° apart in the horizontal plane. The maximum vertical extent (v) increases more than the maximum horizontal extent (h) for various azimuthal views so that observations of v/h yield a one-sided variation above unity. The horizontal mode ($m = 2$) oscillates in the horizontal plane with major and minor axes 90° apart. The vertical axis remains fixed whereas the horizontal axis is larger or smaller than the vertical axis, producing axis ratios with a two-sided variation about unity. All three modes have been observed for water drops falling in air with oscillations about a quiescent raindrop shape rather than a sphere[20].

speed U and $f = U/\lambda$, with an average experimental uncertainty of only 3% in the measurement of f

The streak observations substantiate our conclusions based on the behaviour of the scatter in axis ratio small raindrops oscillate at the fundamental harmonic in the transverse and axisymmetric modes At the onset of eddy shedding the fundamental harmonic is excited, as might be expected from the match in frequencies (Fig 3) Oscillations occur in the transverse mode perhaps as a response to pressure changes caused by eddies detaching from alternate sides of the upper pole At larger sizes the oscillation response to eddy shedding is the axisymmetric mode of the fundamental harmonic, despite the poor match of $n = 2$ with the shedding frequencies[15-19]

The cause of the broad coupling between the fundamental mode and eddy shedding is unknown One possibility is that, once oscillations become large enough, shedding is triggered by shape changes, thereby shifting the shedding frequency to the oscillation frequency Another possibility is a subharmonic coupling of eddies to the oscillations If pressure patterns were alternatively in and out of phase with the distortion, this could explain why the transverse mode is not excited It is unclear how the forcing pattern would best match the axisymmetric mode or why the fundamental is preferred to the next higher harmonic

An indication that the observed strong-coupling phenomenon may extend to much larger raindrop sizes is apparent from the consistency of our axis ratios with those from the differential reflectivity, Z_{DR}, measurements in rain[6] (Fig 1) As Z_{DR} is proportional to the logarithm of the ratio of backscattered powers for radar pulses having vertical and horizontal polarizations, it is directly related to the axis ratio of raindrops The variation in axis ratio given by the dashed curve in Fig 1 was devised to rectify values of Z_{DR} measured with a high-resolution radar (Chilbolton, UK) with values calculated from observed raindrop size distributions This postulated shift in axis ratio, which was applied as an average effect from 1 to 3 mm diameter, is a likely consequence of raindrop oscillations promoted by eddy shedding, at least for small raindrops The occurrence of raindrop oscillations for $d = 2$–3 mm is also supported by recent airborne observations of raindrop shape[5] Such oscillations of moderate-size raindrops probably originate from collisions[11], but may persist because of intrinsic aerodynamic forces, for example from feedback of the varying aerodynamic pressure or drag, opposing the viscous damping of oscillations

To obtain further data on larger drops, we plan to extend our measurements of natural shapes up to 4 mm in diameter by using our experimental methods in a seven-story experiment A careful analysis of shape variations, oscillation amplitudes and oscillation frequencies should uncover more of the mysterious physics that underlies raindrop oscillations, and provide valuable information for understanding the scattering of microwave radiation in rain □

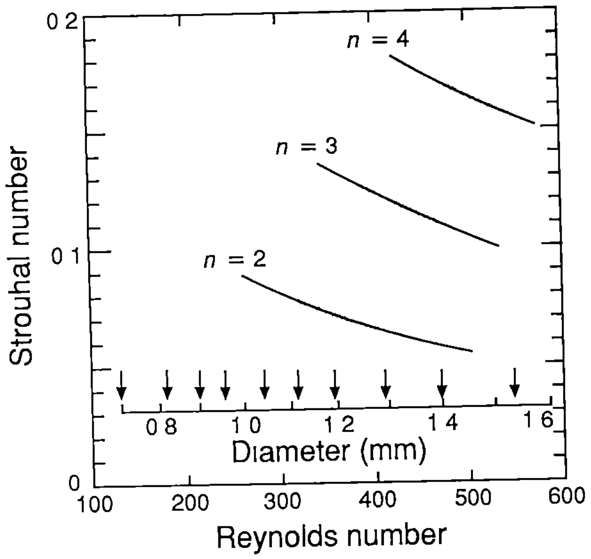

FIG 3 Dimensionless frequency (Strouhal number = fd/U) as a function of water-drop diameter and dimensionless flow parameter (Reynolds number = dU/viscosity) The oscillation frequencies for water drops in air are given by curves for harmonics $n=2, 3$ and 4 Previous measurements of eddy shedding frequencies are shown by the stippled area for drops[15,16] and rigid spheres[17] falling in liquids in a region with Strouhal number <0 15 and for supported spheres[18,19] in a region with Strouhal number >0 15 These data are for nonoscillating drops and rigid spheres The arrows show sizes for drops falling in air in the present experiment

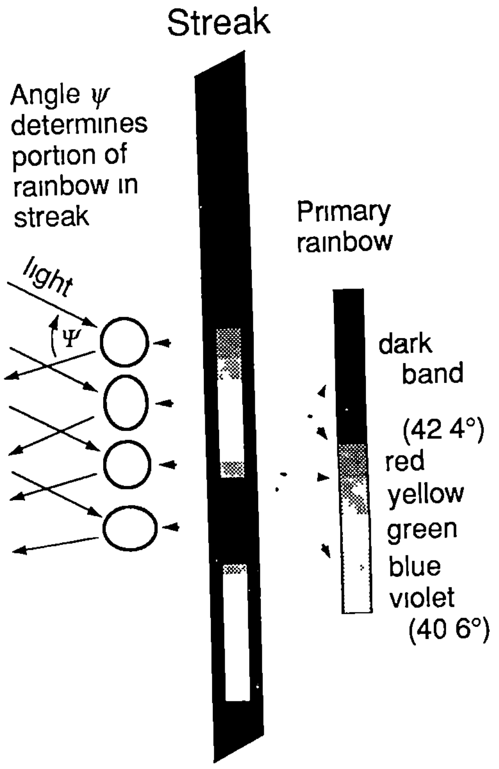

FIG 4 Schematic of modulated fall streak showing the associated drop oscillation and rainbow The oscillation frequency was measured from the spacing of dashes in photos of the fall streaks The dotted arrows show how portions of the fall streak correspond to the origin of colour in the rainbow, and how drop distortions yield a change in angle Ψ The angles are shown for red and violet Colours are weak, except near red, because the width of the light allows incident rays over a range of angles, thereby mixing the adjacent colours

Simulation of the regional climatic impact of Amazon deforestation

J. Lean & D. A. Warrilow*

Dynamical Climatology Branch, Meteorological Office, Bracknell, Berkshire RG12 2SZ, UK
* Present Address Global Atmosphere Division, Department of Environment, London SW1P 3PY, UK

THE Amazon basin contains about half of Earth's Tropical forest[1]. Population pressure and subsequent demands for crop production, timber and firewood have led to rapid deforestation Quantitative estimates of the rate of deforestation from analysis of Landsat observations indicate that rates are increasing exponentially in many regions[2,3], but the precise figures are not known[4] Removal of the protection provided by natural cover can lead to soil erosion, disturbance of the ecosystem and reduction in species diversity[5] Here we report results from a three-year simulation, using a general circulation model, in which we replace Amazon tropical forest and savannah with pasture The simulated local climate response was dominated by a weakened hydrological cycle, with ess precipitation and evaporation and an increase in surface temperature. The reductions in precipitation and evaporation were mostly caused by changes in surface roughness and albedo: decreased roughness dominated the reduction in evaporation (and the increase in temperature), whereas the increased albedo was the main cause of a decrease in the moisture flux convergence (measured as the difference between precipitation and evaporation) contributing to the decrease in precipitation.

Within the Amazon basin, it is estimated that 50% of the rainfall is derived from local evaporation[6], and it has been suggested that a significant reduction in tropical forest might reduce evaporation and rainfall[7] Recently, various studies concerning the impact of surface changes on climate have been carried out using three-dimensional atmospheric global climate models (AGCMs) A review of tropical deforestation experiments[8] shows that substantial differences exist between the schemes for representing physical processes (parameterizations) and between methods used to simulate land transformations in AGCMs As a result AGCMs have not presented a uniform picture of the potential effects of deforestation on climate The use of rather simple land surface schemes and the lack of grid-scale data with which to calibrate the models make the applicability of the results uncertain Some common points, however, have emerged from these simulations First, albedo, roughness and surface hydrology are the most important variables for the representation of land transformation Second, results are sensitive to the parameterization processes in the model, to the choice of vegetation and soil parameters and the soil-moisture field as input data, and the climatology of the AGCM Over the past few years more realistic land surface parameterizations have been included in various AGCMs including that of the UK Meteorological Office

Here we describe experiments that were carried out using the $2\frac{1}{2}^\circ \times 3\frac{3}{4}^\circ$ resolution AGCM described in ref 9, but including a more complex representation of interactive cloud processes[10] The land surface parameterization (D A W , A B Sangster and A Slingo, unpublished results) includes a four-layer soil temperature scheme Interception of precipitation by a vegetation canopy is represented, allowing zero resistance to re-evaporation and potentially a more realistic partitioning of energy between latent- and sensible-heat fluxes The hydrological scheme diagnoses surface runoff from the excess of rainfall over infiltration capacity (accounting for the spatial variability of rainfall statistically), and subsurface runoff from the gravitational drainage of soil moisture[11] Geographical variation of land surface and soil types is based on the work of Wilson and Henderson-Sellers[12] Their original $1^\circ \times 1^\circ$-resolution primary- and secondary-vegetation datasets were used to create spatially varying datasets of 17 soil and vegetation parameters which were interpolated onto our $2\frac{1}{2}^\circ \times 3\frac{3}{4}^\circ$ model grid[13]

We ran three-year control and deforestation experiments, starting at the end of June All grid boxes in South America north of 30° S defined as either tropical forest or savannah on the $1^\circ \times 1^\circ$ grid were replaced by tropical pasture Soil characteristics except surface infiltration capacity, were left unaltered We give the results for an area in the southern part of Amazonia where the largest change in land surface characteristics occurred (see Fig 1)

We compare the control simulation with observation in Fig 1 and Table 1 The model simulates accurately the spatial distribution of rainfall for both the Southern Hemisphere winter and summer, although the dry areas are more extensive in winter over the southern Amazon and rainfall is slightly excessive in summer over the basin Looking particularly at the region concerned, Fig 2*a* shows this slight amplification of the seasonal cycle in the control rainfall simulation The annual mean values of other variables, compared in Table 1, show that the control simulation is quite realisitc We note that it is extremely difficult to obtain accurate estimates of such quantities because observations are too sparse to provide grid-square means Runoff is

† Deforested simulation. averaged over three years

‡ Observations

only quoted for a particular basin and is not strictly comparable to that from the region shown. Evaporation is based on only a few direct observations and empirical calculations.

Comparison of surface quantities for a single model grid square with data[14] for a site in central Amazonia indicates that modelled total evaporation differs by 15% from the observed, and that the modelled canopy evaporation is 71% compared with the observed 25% of total evaporation. Overestimation of canopy evaporation is probably present in other land surface schemes and this may be due[15] to the extension of a single-point description of the rainfall interception process to the grid-scale area in a region where convective rainfall events dominate.

Table 1 also summarizes the effect of deforestation on local climate for a variety of surface variables from each experiment. The hydrological cycle is significantly weakened by deforestation, with a reduction in evaporation, rainfall and runoff. Surface runoff is reduced as the decrease in intensity and frequency of rainfall events predominates over an opposing tendency for increased runoff that is the result of a reduction in infiltration capacity. The decrease in available soil moisture occurs as a result of the marked reduction in root depth (from 127.4 cm to 61.9 cm). Pasture reflects more solar radiation than does forest, which is a very efficient absorber and scatterer of short-wavelength radiation. Consequently, the net energy absorbed by the surface was diminished, with the mean albedo increased from 0.136 to 0.188. By itself, a reduction in net absorption of radiation at the surface would result in a temperature decrease but this is offset by a reduction in evaporative cooling and so there is an overall rise in temperature. The decrease in the latent-heat flux was due to the reduction in roughness (from 0.79 m to 0.04 m) and, at some times of the year, the water availability, this decrease is primarily responsible for the marked increase in the Bowen ratio (defined as the ratio of sensible to latent heat).

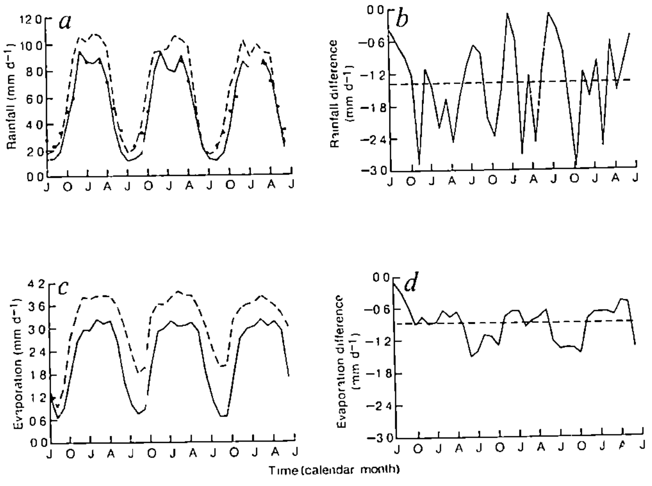

FIG. 2 *a*, Monthly mean precipitation (mm d^{-1}) averaged over the region under consideration for three years starting in July. The broken line represents the control simulation (C), the solid line the deforested simulation (D) and the dots the observed rainfall (O) (ref. 21). *b*, Simulated monthly mean difference (D − C) of precipitation (mm d^{-1}) averaged over the region under consideration for three years starting in July. The broken line represents the mean difference precipitation. *c*, As for *a* but for evaporation (mm d^{-1}). *d*, as for *b* but for evaporation (mm d^{-1}).

Figure 2 depicts the seasonal variation of precipitation and evaporation for the control simulation, the 'deforested' simulation and the difference between the two. There is a consistent decrease in precipitation and evaporation throughout the year although rainfall changes exhibit greater variability. There is also a seasonal variation in the change in evaporation with the maximum differences occurring in the winter and spring when evaporation is controlled by the limited availability of soil moisture.

To gain a better understanding of the physical mechanisms that are operating, two eight-month simulations, using the same initial data as the control and deforested experiments, were carried out to investigate the relative impact that is due to changes to albedo and roughness alone. Table 2 summarizes the differences between some of the surface variables of the control simulation and those of the experiments with increased albedo (from 0.136 to 0.188), decreased roughness (from 0.79 m to 0.04 m), and total deforestation. Precipitation within the Amazon basin originates from two sources—from the recycling of water vapour released during evapotranspiration, and from the moisture flux convergence into this area. The decrease in moisture flux convergence (measured as the difference between precipitation and evaporation) is due mainly to increased albedo although there is some contribution from the change in roughness. Increased albedo reduces the heat source, weakening ascent and boundary-layer convergence[16]. Reduced roughness can also decrease the moisture flux convergence as it weakens the boundary-layer convergence (associated with frictional drag near the surface) into the continental surface-pressure low[17]. Decreased roughness dominates the reduction in evaporation and the associated temperature increase. The forest canopy is wet for most of the year (implying low surface resistance) and so a decrease in evaporation is to be expected as roughness decreases[18]. Increased albedo reduces the available energy for upward turbulent transfer of latent energy. Hence, changes in both albedo and roughness make a major contribution to the overall decreases in precipitation and evaporation in the deforestation experiment.

Our results can be compared with a 13-month simulation carried out by Dickinson and Henderson-Sellers[19]. They incorporated a land surface scheme with a canopy in the National Center for Atmospheric Research Community Climate Model which has a grid resolution of 4.5°×7.5°. They assumed that all of the Amazon tropical forest in South America was replaced by impoverished grassland. Both experiments show a decrease in evaporation (~16 mm $month^{-1}$ in ref. 19 (from their Fig. 11) compared with 26 mm $month^{-1}$ here) and an increase in surface temperature (with a range of 2.0–5.0 °C over the 13 months in ref. 19 compared with the average of 2.4 °C here). Dickinson

TABLE 2 Summary of the differences in surface variables

Surface Quantity	A − C*	R − C†	D − C‡
Evaporation (E) (mm d^{-1})	−0.20	−0.43	−0.61
Precipitation (P) (mm d^{-1})	−0.75	−0.69	−1.34
$P - E$ (mm d^{-1})	−0.55	−0.26	−0.73
Temperature (°C)	−0.10	2.24	1.98

These results are averaged over eight months.

* A, increased albedo simulation, C, control simulation.

† R, decreased roughness simulation.

‡ D, 'deforested' simulation.

and Henderson-Sellers, however, found no detectable change in rainfall, in contrast to the average decrease of 1 3 mm d^{-1} (20%) shown here

Our results indicate a stronger impact of deforestation on the local climate than do previous GCM experiments We note, however, that these results are highly sensitive to the formulations of the model and our ability to make firm predictions based on these results is inhibited by the lack of observations in forested and deforested areas with which to verify these schemes More ground-based measurements of atmospheric and hydrological processes, together with global data sets of surface vegetation types derived from satellite data, could aid in this development, both as input to the model and to validate and adjust the land surface parameterizations[20] Nevertheless, our results indicate that deforestation can cause significant local climatic perturbations and further efforts should be made to improve our understanding of the processes involved ☐

Climate patterns revealed by pollen and oxygen isotope records of a Tyrrhenian sea core

Martine Rossignol-Strick & Nadine Planchais

Laboratoire de Palynologie, URA 327 du CNRS, Universite de Montpellier II, Sciences et Techniques du Languedoc, 34095 Montpellier Cedex 2, France

THE analysis of pollen from marine cores has produced continental palaeoclimate records which have been directly correlated with the oxygen isotope record of global ice volume and regional climate[1-3] Here we tie the palaeoclimate of southern Europe to this global climate signal by reporting continuous pollen and δ^{18}O records of a well-dated core in the Tyrrhenian Sea for the time span of 55–9 kyr BP These records show a strong covariation between the marine δ^{18}O reversed curve and a good terrestrial climate indicator, namely the pollen abundance of deciduous oak from the upland sub-humid Mediterranean forest of southern Italy and Sicily, which seems mainly constrained by moisture variation The *Artemisia* and grass pollen abundances document the shift between continental semi-desert and oceanic steppe climates Repetitive successions between 55 and 33 kyr BP of grass, oak, *Artemisia* and *Abies* pollen abundance peaks occur in locked phase with δ^{18}O depletion events and indicate that regional vegetation cycles closely accompany deglacial pulses of global extent

The stratigraphy of core KET 8003 (38°49 2′ N, 14°29 5′ E, 1,900 m water depth, 1,030 cm length), is based on the oxygen isotope variation in the foraminifer *Globigerina bulloides*, measured at 10-cm intervals[4] (Fig 1) Tests of calcite formed by marine organisms reflect the fluctuations of ^{18}O in sea water Because ^{16}O evaporates more readily than ^{18}O, the ^{18}O/^{16}O ratio is low in continental ice sheets and high in the glacial ocean Conversely, during interglacial periods, the oceans are depleted in ^{18}O The basis of this core lies within the last Interglacial, that is isotope stage 5e at 125 kyr BP The chronology is based on six interbedded ash layers that have been correlated by their chemical composition with lava flows in southern Italy[4,5] that were dated by ^{14}C and K/Ar analysis to be between 55 and 12 kyr old, and on the initiation of the deglaciation after the last glacial maximum (Termination I), globally seen at 15 kyr BP[6] Because the sample set for pollen was taken subsequently, it has a 2-cm offset from the isotope set Pollen has not been recovered below 580 cm

Southern Italy was also the source area for pollen in core KET 8003 both volcanic ash and pollen are airborne We have identified 128 pollen taxa and excluded *Pinus* from the pollen sum The large production and strong resistance of *Pinus* pollen to aerobic bacterial degradation, probably linked to its high sporopollenin content[7], often result in over-representation in marine cores[8] Here we describe the variation of the pollen percentages of *Quercus*, *Abies*, *Populus*, Poaceae, *Artemisia*, Chenopodiaceae and *Ephedra* A heavy pollen producer, *Quercus* (oak) is the only deciduous tree whose pollen is continuously present in the core Oak pollen percentage in core KET 8003 shows no correlation with (1) the pollen sum, (2) total pollen concentration per gram of sediment and *Pinus* pollen abundance These two observations indicate respectively that the percentage is not an artefact of the analysis procedure nor is it controlled by differential pollen preservation before and during burial on the sea floor

The δ^{18}O and oak pollen abundance series of core KET 8003 co-vary in phase with each other The peaks in oak pollen abundance usually just precede those of δ^{18}O depletion This, however, is an artefact of the sampling offset and does not preclude the existence of coincident peaks The partitioning of the records into two types of intervals, one of δ^{18}O decrease/oak pollen increase (climate improvement) and the other with the reverse relationship (climate deterioration) yields a high correlation between the two data sets during the former intervals ($r = 0$ 84), and a lower one during the latter ($r = 0$ 55)

During isotope stage 3, characterized by generally high δ^{18}O values which denote globally glacial conditions between 69 and 24 kyr BP, there are four closely matched events of δ^{18}O depletions and oak pollen peaks between 580 and 240 cm which can be seen as short-lived deglacial pulses Each of the two oldest peaks in oak pollen abundance, dated before 50 kyr BP, is set between two other abundance peaks an earlier one of Poaceae and a later (and larger) one of *Artemisia* This repetitive succession amounts to a pattern also seen later, during the first half of the deglaciation after 15 kyr BP Whereas the abundance of oak pollen decreases above 472 cm, that of *Abies* pollen increases strongly between 450 cm and 400 cm, and *Hedera* and *Ilex* pollen appear sporadically We suggest a correlation with the peaks of *Abies* pollen seen between 2,200 and 2,045 cm in the record of Lake Monticchio in southern Italy[9] After 33 kyr BP, *Quercus* and *Artemisia* pollen abundances become minimal and Poaceae is the prevailing herbaceous pollen taxon

During the glacial maximum (240–190 cm), corresponding to part of isotope stage 2 (24–11 kyr BP), the average abundance of oak pollen is at its lowest Until mid-stage 2, the dominant the uplands, *Abies* from the cool humid montane forest A ense, humid grass steppe is seen today from Hungary through e Ukraine (annual precipitation 350-455 mm) along 45-50° N, northern Kazakhstan at 50-55° N (ref 19) With a thick snow over providing ample spring moisture, the Ukrainian climate partly oceanic, and with a precipitation peak in summer, it partly continental The late summer drought eliminates eciduous trees, leaving the steppe a residual vegetation formaon The lowland semi-desert seen today in Middle Asia along 0° N is more arid (80-280 mm precipitation) and more connental (21-24 °C in July, −12 to −16 °C in January) than the krainian grass steppe Forests of deciduous trees below *Abies* orests today grow on the northern and western slopes of the ian-Shan mountains above the desert lowland that lies south f the semi-desert

We interpret the vegetation that produced the pollen record rom stage 3 as repeatedly shifting, in the lowlands, from semiesert to steppe, with a predominance of the former under a ghly continental climate The succession of abundance peaks or oak pollen indicates that pulses of moisture and temperature ncrease occurred in the uplands, followed by episodes of still et but colder climate, signalled by the high abundance of *Abies* ollen The rapid rise in oak pollen abundance after each glacial nterval indicates the ability of that tree to take advantage of he earliest moisture increase in a continental climate This can e accounted for by the 'hardening' process the survival of ormant buds is improved by low temperature (−25 °C and even -30 °C) when it occurs in January and February[19]

The scarcity of oak pollen during the last glacial maximum ndicates that pollen production decreased and/or that source reas were very restricted Isolated refuges of deciduous temperte forest have been hypothesized in the mountains of southern Europe, low enough to avoid extreme autumn cold, fatal to the ormant buds, and high enough to provide adequate summer oisture by adiabatic cooling of ascending air[13,14 20 21] The eplacement of the present Mediterranean vegetation of southern Italy at sea level by a grass steppe of Ukrainian type would result from a temperature decrease of 1-4 °C in July, to 24-21 °C, and of 10-24 °C in January, to 0 to −14 °C, and a 440-540-mm decrease in annual precipitation, to 450-350 mm Provided that precipitation would be ⩾500-600 mm, then a refuge zone for deciduous trees could exist up to 600 m, where temperature would be 17 4-20 4 °C in July, −3 6 to −17 6 °C in January (with a 0 6 °C per 100-m pseudoadiabatic lapse rate[22]) These temperatures compare well with those at the northern and north-east limits of the deciduous oak distribution in eastern Europe[19] Thus it might be that the lower temperatures during lacial times would not have restricted or eliminated the oak, whereas moisture decrease could have, as also suggested by estimates of glacial climate in Greece[14]

A modern analogue for the vegetation that produced maximum *Populus* pollen abundance at the onset of deglaciation in core KET 8003 is the aspen trees, which in the eastern Ukrainian steppe surround each small ground depression occupied by a rain-fed round lake (called a 'pod')[19] Although higher than in the treeless steppe, precipitation (~480 mm) is still not sufficient to develop a drainage system

During the early part of deglaciation, ~14 kyr BP while the upland oak population increased in the Tyrrhenian basin, the lowland oceanic grass steppe of the glacial maximum progressively gave way to a continental semi-desert, most widespread during the Younger Dryas

Reconstruction of the precipitation variation in Les Echets in south-east France[23] (Fig 2) can be compared with our oak pollen per cent variation In the two time-series, during stage 3, moderately high values are seen from 60 to 43 kyr BP, and low values at ~40 kyr BP, increasing during the last part of stage 3 Stage 2 is dryer and oak values are minimal, precipitation starts to increase at 15 kyr BP, as to the deciduous trees

The climatic significance of this isotope record is complex The 1 3‰ isotope effect of the global ice volume[24] accounts for 54% of the 2 40‰ δ^{18}O range between glacial maximum and the core top The 1 1‰ remainder is due to regional sea surface temperature and salinity variations As the isotope and oak pollen variations have comparable amplitudes in the strong deglacial pulse of early stage 3 from 560-542 to 472-466 cm depth (Δ (δ^{18}O) = 1 48‰, Δ oak pollen = 14%) and in the transition from glacial maximum at 190 cm to Allerod at 110-120 cm (Termination Ia) ($\Delta\delta^{18}$O = 1 37‰, Δ oak pollen = 16%), it is conceivable that the isotope shift of stage 3 could record an ice-volume decrease comparable with that of the first phase of deglaciation This implication, which requires that the range of salinity variation is also similar, is based on the present link between the formation or rejuvenation of atmospheric depressions, generating the regional precipitation to which the oak population is sensitive, and the high Tyrrhenian sea surface temperature[25,26]

Comparison of the course of events after the deglacial pulses of stage 3 and Termination Ia shows that the reversal to glacial conditions in the isotopic composition of the sea and in the vegetation of southern Italy was complete after 49 kyr BP, and partial after 11 kyr BP during the Younger Dryas We hypothesize that this difference might have some link with the observations that (1) the July insolation peak at 56 kyr BP was lower than that at 11 kyr BP (at 60° N, respectively 7 and 10% higher than present[27]) and (2) the rate of insolation increase for July was smaller at the transition from full-glacial stage 4 to stage 3 than at that from full-glacial stage 2 to stage 1 (at 60° N, respectively 7 2 cal cm^{-2} per 1,000 yr between 70 and 56 kyr BP, and 8 5 cal cm^{-2} per 1,000 yr between 22 and 10 kyr BP) The Termination II deglaciation between 1,350 and 1,250 kyr BP does not, to present knowledge, record a reversal similar to the Younger

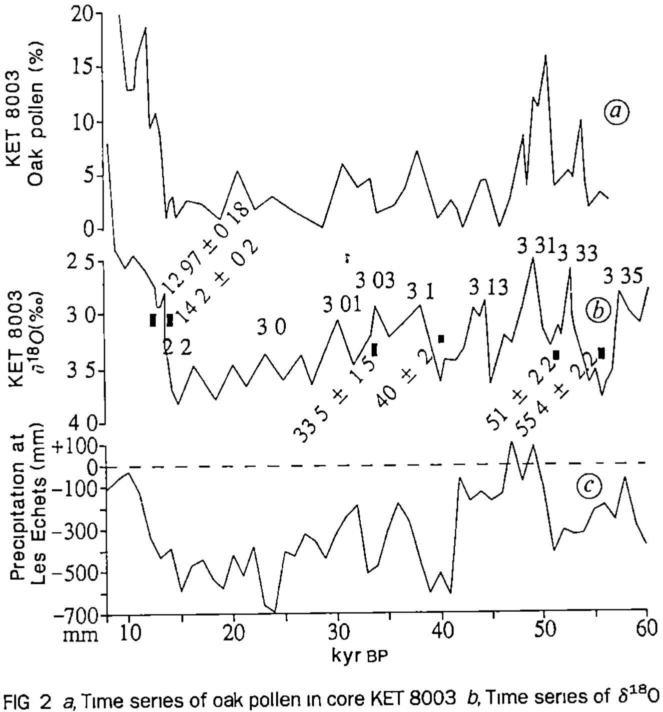

FIG 2 *a*, Time series of oak pollen in core KET 8003 *b*, Time series of δ^{18}O in core KET 8003 Chronostratigraphy based on radiometrically dated tephra (black rectangles) and the initiation of deglaciation at 15 kyr BP, isotope event 2 2 Event 3 0, the stage 2/3 boundary, is set at 24 kyr BP Isotope events after ref 5 *c*, Reconstruction of variation in annual total precipitation expressed as deviation from the modern value (800 mm) in Les Echets, southeastern France[23] Error bars omitted for simplification On comparing this with the KET 8003 time series, a lack of radiometric ages in Les Echets before 25 kyr BP should be noted The major precipitation peak in Les Echets at 49-46 kyr is synchronous with the peak in *Abies* pollen abundance in KET 8003

Dryas[28] The link of Termination II with a higher insolation peak and more rapid pace of insolation increase is consistent with the steering of the climate system

Broecker hypothesized that it is the shut down of the Atlantic Ocean conveyor belt that brought about the cooling trend in the climate jumps after 11 kyr BP and during stage 3 (refs 29 and 30) If this is the case, the heat that is no longer transported from low to high latitudes by ocean surface currents would accumulate in the tropical ocean There it would increase the convective activity of the Intertropical Convergence Zone, which would reactivate the atmospheric Hadley cell[31,32] and restore the poleward oceanic heat transport Thus the conveyor belt closing-off is a self-limiting process which can only be temporary

Inclusion in rapidly accumulating marine sediments of tl pollen originating in all elevations in the rimlands of the Ty rhenian Sea is a process that provides an integrated picture the vegetation through its rapid changes The complex patte of these changes documents the palaeoclimate of southe Europe during a timespan that is here particularly well date The covariation of the oak pollen abundance with the isotop composition of sea water, which is shaped in part by the glob volume of the ice sheets, testifies to the coherence of the fluct ations of the climate system at the millennial timescale in regional and global expressions

SEISMIC imaging of Precambrian cratons holds the promise of deep structural mapping and interpretation of fundamental crustal construction processes Deep structures may be identified by tracing reflections to the surface[1], particularly in exposed crustal cross-sections[2] elevated along deeply penetrating faults, but many such cross-sections have structural orientations too steep for successful reflection imaging (like the Ivrea zone[3]) or occur in plate-boundary settings not representative of continental interiors By contrast, the Archaean greenstone terrain exposed in the Kapuskasing uplift of Canada[4,5] has gently dipping structures, and an intracratonic setting within the Superior Province, thus providing an opportunity to examine the third dimension of continental crust down to 25–30 km palaeodepth[6] Here we present new seismic reflection data which, although generally supportive of structural models based on surface geology[4], gravity modelling[5] and seismic-refraction studies[7,8], also indicate that the Kapuskasing structure is a relatively thin thrust sheet containing seismically reflective sequences of high-grade rock which may be analogues of seismically reflective *in situ* lower crust.

Superior Province, the largest preserved Archaean craton, is well known for its greenstone belts, hosting major gold an base-metal deposits The east-trending Abitibi–Wawa belt (Fi 1) of low-grade metavolcanic and granitoid rocks is transecte by the north-east-striking Kapuskasing uplift (KU), distin guished by high-grade metamorphic rocks producing positiv gravity and aeromagnetic anomalies[9] The KU is interpreted a a slab of deep crust[4,10,11], thrust upward along the west-dippin Ivanhoe Lake fault zone (ILFZ) A 120-km transect across th KU from Lake Superior to the ILFZ crosses greenstones wit 2–3 kbar metamorphic palaeopressures[12], amphibolite-facie (5–6 kbar) tonalite of the Wawa gneiss terrane, a density[13]-velocity[14] boundary inferred to be a Conrad-type discontinuity and heterogeneous, layered, high-grade (7–9 kbar) gneisses o predominantly magmatic origin in the Kapuskasing zone Increases in metamorphic grade and pressure across the K indicate an easterly deepening erosion level, from regional background values of 6–9 km in the greenstones to 25–30 km nea the ILFZ With increasing palaeodepth, decreasing U–Pb, Ar–A and Rb–Sr ages show that rocks from deeper levels remaine hot for longer and cooled more slowly[15] The crust attained mos of its 40 ± 5-km thickness in the interval 2 75–2 68 Gyr, throug early arc volcanism and plutonism, followed by shortening metamorphism and renewed arc magmatism[5] Seismic refractio results map a zone of high velocity (6 6 km s^{-1}) extending fron near the surface in the Kapuskasing zone to normal depths o ~20 km under the greenstones to the west[7,8] The crust thicken from regional values of 35–44 km to >50 km beneath the Kapuskasing zone

Since 1984 LITHOPROBE has supported a wide variety o geological and geophysical studies aimed at defining crustal-scale geometry and evolution through the Kapuskasing 'window' A key component of these studies is the 1987–88 seism reflection survey, three lines, labelled 1, 2–3–4 and 6, crosse the southern KU (Figs 1 and 2) Line 1 extended south to north from the Abitibi belt into the Kapuskasing zone Composite line 2–3–4, comprising three conventional segments and two undershoots regions containing reflection points but having no surface reflection sources or receivers, crossed the Kapuskasing zone cluding the Shawmere anorthosite complex parallel to the gional east–west structural grain In addition to the relatively onventional regional survey, line 2 was resurveyed using highsolution parameters, which yielded significantly more detail bout the shallow structure (compare Fig 3*a* and *b*) Finally, ne 6 sampled the southern end of the KU

The stacked seismic sections (Figs 2, 3) show many coherent vents although the image quality varies along the profiles pper crustal reflectivity is generally high along all lines, but e reflection character varies with the geological terrane Porons of the seismic lines that cross tonalitic gneiss and granite f the Abitibi belt yield prominent reflections, dipping west and orth at >30°, from near the surface to at least 13 s beneath the rface exposure of the KU The uppermost zone of strong eflectivity on lines 1 and 6 (H on Fig 2*a*, *c*) projects 10 km eyond the south end of the lines into outcrops of felsic gneiss nd 'homogeneous' granite

Reflectivity of the KU granulites and the seismic image of e ILFZ are best represented on line 2-3-4 Within the Kapusasing zone, shallow (0 2–2 s) 'E' reflections (Fig 3*b*) dip 15° W along the profile and can be traced short distances to urface exposures of mafic, tonalitic and anorthositic rocks terlayered on a 10–30-m scale[16] These sill-like intrusive bodies ave seismic volocities (7 23, 6 55, 7 26 km s^{-1} respectively)[17] nd dimensions appropriate to generate significant reflections lthough direct correlation of reflections and lithology would equire short drill holes[18] The basal reflection of the E package ', Fig 2*b*) locally truncates events above and below it, suggestg hanging-wall and footwall cutoffs by a splay of the ILFZ[19] pair of gently west-dipping reflections (A, B in Fig 3) steepen pward from 2–3 s Associated structures can be followed along istinct reflections or truncations of events to near the surface ace of the ILFZ (Figs 2*b*, 3), using geometry based on migrated ections Here the reflections may correspond to zones of catalasite and mylonite up to 70 m thick[11] To the west, reflections and B merge with the base of the E package to become a iffuse zone extending to ~4 s at the western end of the comosite line The ILFZ is not represented by distinct reflections n the other lines, but is constrained by non-offset and nonuncation of reflections to dip ~15° N along line 1 and ~15° NW long line 6 The inferred extension of the ILFZ occurs at a ommon depth of ~3 8 s at the intersection of the lines and ossibly continues to ~5 s at the north end of line 1 (I, Fig 2*a*)

In the central and western parts of the survey area, the Kapuskasing zone and Wawa gneiss terrane are represented down to 6–8 s by discontinuous, rolling sub-horizontal reflections up to 5 km long (Fig 2) Again, shallow reflections can be related to rock exposures A zone of sub-horizontal reflectivity at 0 3–3 s at the northern end of line 1 (F, Fig 2*a*) is consonant with gently undulating surface structure in the overlying high-grade paragneiss, concave-down reflective zone G occurs beneath a structural dome of tonalitic gneiss Shallow reflections (J) from the thin wedge of hanging-wall rocks at the north-west end of line 6 are sub-horizontal or gently west dipping, corresponding to surface structural geometry[20]

The depth to the base of strong reflectivity varies along each line and between lines Beneath line 2-3-4 it occurs at 13 s in the east, at 6 s in the east central region, and undulates between 11 and 13 s elsewhere Reflections are abundant to at least ~13 s beneath the Abitibi belt on lines 1 and 6, but decrease markedly at 8–9 s to the north The variation in depth extent of reflectivity does not seem to correlate with crustal thickness, estimated at 14–16±0 6 s over the area of the reflection survey (Fig 1)[7,8] Although some of the change in reflectivity is attributable to varying surface conditions, it is possible that a deep-crustal deformation zone, characterized by disrupted structures and weakened reflections, characterizes the crustal bulge beneath the KU

The reflection sections have in common (1) shallow (<2 0 s) sub-horizontal or west-dipping reflections that can be projected short distances to surface structure in both the granulite-facies Kapuskasing zone and amphibolite-facies Wawa gneiss terrane, (2) images of the ILFZ, a structure dipping 16° north-north-west that can be traced to 4–5 s, (3) prominent west or north-dipping reflectors beneath the Abitibi subprovince, (4) reflections to ~13 s in the Abitibi crust by contrast with absent or less coherent reflections below 6–8 s beneath the KU, and (5) no discrete reflecting zone or marked reduction in reflectivity corresponding to the refraction-determined Moho

Based on the reflection image of the ILFZ, the KU is a much thinner feature than inferred from earlier gravity modelling[4] Traced to 4 s on line 2-3-4 and 5 s on line 1, the fault probably continues to dip northwesterly to a depth of ~20 km (6 6 s) based on refraction data from further west[7] These constraints allow us to estimate the horizontal shortening required to elevate the granulites to the surface Their depth of origin is ~20 km,

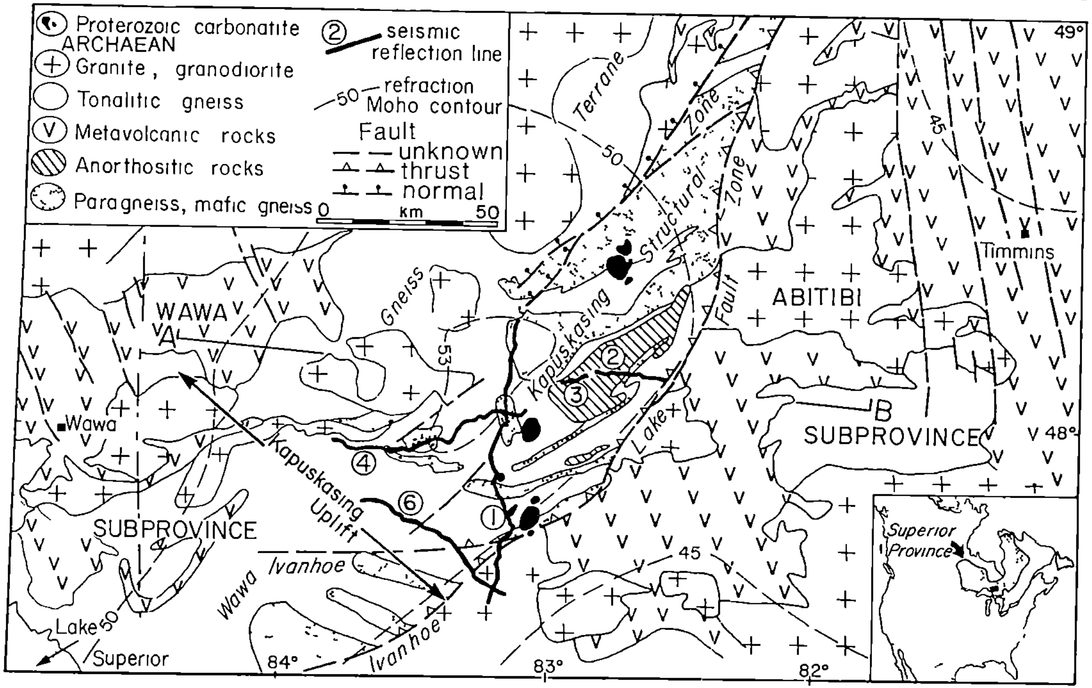

FIG 1 Simplified regional geological map with locations of seismic-reflection lines and Moho contours[8] in km

based on the palaeopressure difference of ~6 kbar between the low-grade rocks near Lake Superior and the Kapuskasing granulites, and on refraction data, linking the 6 6 km s^{-1} velocities of the Kapuskasing zone to normal depths for this velocity (20 km) near Lake Superior The shortening estimate then depends on assumptions concerning fault geometry north-west of the region surveyed If the fault dips consistently at 16° to 20-km depth, approximately 70 km of shortening is required, whereas the presence of a ramp near the north-west edge of our survey[19] would lessen this to a minimum value of 55 km

Similar magnitudes of overthrusting have been documented in many orogenic belts[21], where décollements must extend hundreds of kilometres to plate boundaries to balance shortening on a lithospheric scale Although the crustal geometry is relatively well constrained, the lateral continuation of the ILFZ i undetermined and therefore the mechanism of crustal deforma tion that caused the KU is not fully resolved Structural model that account for the shortening and associated >10-km increa in crustal thickness (Fig 4) include (1) the detachment roo at an ancient plate boundary to the north-west[19], (2) convergenc from the south-east caused underthrusting of the Abitibi rock beneath the KU (tectonic delamination[22]), and (3) brittle short ening of the upper crust was balanced by ductile flow in th lower crust (as in the Zagros collision zone[23])

Although the seismic data provide no direct evidence on th age of thrusting, the inferred 55–70 km of shortening has impli cations for the timing The arcuate 2 45-Gyr (ref 24 Matachewan–Hearst dyke swarm crosses the southern KU wit

IG 3 Comparison of regional and high-resolution LITHOPROBE stacked eismic reflection data collected along the eastern segment of composite ine 2-3-4 Location of the line is shown in Fig 1 and the geological legend n Fig 2 Geology is taken from more detailed maps than shown in Fig 1 The regional data were collected with the following parameters 50-m eceiver spacing, 100-m source spacing, 240 channels, 60-fold coverage, 4 arge vibrators, 12-52 Hz sweeps, 16-s correlated record length, 4-ms ample interval The high-resolution data were collected with the following arameters 20-m receiver spacing, 20-m source spacing, 120 channels, 0-fold coverage, 2 large vibrators, 20-130 Hz sweeps, 8-s correlated record ength, 2-ms sample interval Plotting parameters as in Fig 2 Annotation efers to features discussed in the text

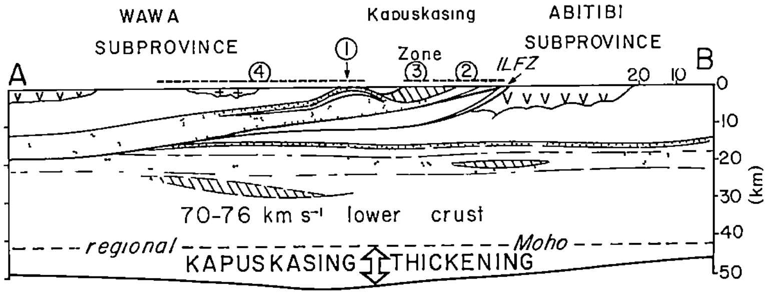

FIG 4 Summary cross-section through the Kapuskasing uplift (legend as in Fig 1), showing 70 km of horizontal shortening by thrusting and ductile thickening, respectively above and below a decollement at ~20 km depth 1 to 4 (circled) show approximate locations of the seismic reflection profiles relative to the sketch Alternative mechanisms that account for the geometry are discussed in the text

only minor offsets[25] Unless the transport direction coincidentally followed the arcuate trend of the dykes, this suggests that major movement preceded 2 45 Gyr, supporting some palaeomagnetic[26] and Ar-Ar age[27] observations and contrasting with inferences[15,28] of principal uplift at ~2 Gyr

To generally apply the model of crustal evolution developed through the three-dimensional Kapuskasing exposure, we must compare the KU seismic signature to that of other regions The general character of the Kapuskasing profiles, with abundant reflections in the upper 8 s, diminishing downwards to ~13 s, some distance above the refraction-determined Moho, is similar to other Precambrian areas[29] but differs from the pattern observed in some younger terranes of transparent upper and reflective lower crust[30] Several explanations for these crustal-scale differences are possible (1) reflectivity is enhanced by some parameter that changes with time (slowly released metamorphic fluids, for example), (2) the Kapuskasing area has a deep, nonreflective component not found in younger crusts (such as a massive underplate), (3) information from young crusts is biased towards extended terranes that have a characteristic structure, or (4) there are fundamental differences in the structure and evolution of Archaean and younger crusts Nevertheless, for the kilometre-scale, laminated, deep-crustal reflections that make up the regional patterns, the reflective, sub-horizontally-layered, high-grade rock sequences at Kapuskasing, with velocities in the 6 6 km s^{-1} range, provide a viable analogue Arc-building processes involving injection of sub-horizontal sheets of mafic and felsic magma, with attendant differentiation, metamorphism and assimilation, may therefore have been widespread during construction of the foundations of the continents □

The hafnium paradox and the role of garnet in the source of mid-ocean-ridge basalts

Vincent J. M. Salters*† **& Stanley R. Hart***‡

* Department of Earth Atmospheric and Planetary Sciences,
Massachusetts Institute of Technology, Cambridge,
Massachusetts 02139, USA

MID-OCEAN-RIDGE basalts (MORBs) are thought to result from melting in the mantle at depths of less than 60 km, in the spinel stability field[1–3]. MORBs have $^{176}Hf/^{177}Hf$ ratios indicating derivation from a mantle reservoir with a long-term Lu/Hf ratio greater than that of C1 chondrite meteorites, yet the measured Lu/Hf ratios in MORB are lower than in C1 chondrites: this is the 'hafnium paradox'[4]. Here we show that the Lu–Hf and Sm–Nd systematics of MORBs require garnet to be a residual phase in MORB melt genesis. This places the onset of melting beneath a mid-ocean ridge at depths greater than 80 km. A sequential melting model, in which melting starts in the garnet stability field and then continues at shallower levels, best explains the combined Nd and Hf isotope systematics, and is compatible with our present geophysical and geochemical knowledge of mid-ocean-ridge magmatism.

Patchett and co-workers[5–7], using hafnium isotopes to constrain geological processes, concluded that, in general, Hf isotopes in oceanic volcanics (MORB and OIB) are well correlated with Nd isotopes[5]. The Lu-Hf isotope system has therefore received only very limited attention in mantle studies. The good correlation between the Nd and Hf isotope systematics is believed to reflect similar behaviour of the parent/daughter ratios, Sm/Nd and Lu/Hf respectively, during mantle differentiation processes. We can use this similarity in behaviour and any deviation therefrom to constrain the MORB melting process.

MORBs are generally thought to form by decompression melting of a spinel lherzolite, followed by fractionation in a magma chamber before eruption. This model implies that the mantle residual to MORB genesis consists of olivine, orthopyroxene and probably some chromium diopside[8]. Estimates for the degree of melting of MORBs ranges from 1–25%[8–10]. Most MORBs are believed to be generated at pressures of at least 8–10 kbar, as the melt is not in equilibrium with orthopyroxene[3,11] below this pressure. In the anhydrous melting of spinel peridotite, the partition coefficients increase in the order Nd, Hf, Sm, Lu[12,13]. Knowledge of the solid/melt distribution coefficients allows coupling of the isotopes, that is parent/daughter ratios in the mantle source can be related to their parent/daughter ratios in the melt. The coupling of the Nd and Hf systematics and the information they contain concerning the parent/daughter ratios of the source and melt have not been modelled before. MORBs form a fairly smooth trace-element pattern on incompatibility (spider) diagrams[12], indicating possible derivation from an anhydrous spinel lherzolite. Sm/Nd, Sm/Hf and Lu/Hf ratios in MORBs are not sensitive to shallow-level crystal fractionation effects, so they will reflect the original source ratios as modified only by the melting process. The $^{176}Hf/^{177}Hf$ and $^{143}Nd/^{144}Nd$ ratios yield information on the long-term Lu/Hf and Sm/Nd ratios in the source.

Figure 1 shows the Lu/Hf and Sm/Nd ratios in MORBs an hypothetical isochrons for a MORB mantle source. All MORB values lie on the left of the 1–3 Gyr mantle isochrons, that is, the Lu/Hf and Sm/Nd ratios in MORB are too low for the observed $^{176}Hf/^{177}Hf$ and $^{143}Nd/^{144}Nd$. This indicates that the process generating MORBs has produced significant fractionation (decrease) of the Lu/Hf and Sm/Nd ratios. This observation is the Hf paradox, in that the Lu/Hf in MORB is lower than C1 chondrite, whereas $^{176}Hf/^{177}Hf$ indicates a long-term Lu/Hf higher than C1[4]. As for Sm/Nd, the Lu/Hf ratio in C1 chondrite is also the best estimate for the bulk-Earth (BE) Lu/Hf ratio[14].

To quantify these parent–daughter fractionations, we chose a 2-Gyr model age for the MORB source[14,15], a choice of 1.0 or 3.0 Gyr would not alter the arguments below. The difference between the mantle isochron value and the measured MORB value can be expressed as $\delta_{Sm/Nd} = ((Sm/Nd)_{2Gyr} - (Sm/Nd)_m)/(Sm/Nd)_{2Gyr})$, where $(Sm/Nd)_{2Gyr}$ is the calculated Sm/Nd based on the measured present-day $^{143}Nd/^{144}Nd$ of a basalt and $(Sm/Nd)_m$ is the measured Sm/Nd in this basalt. $\delta_{Lu/Hf}$ is defined in the same way, and $\delta_{Lu/Hf}$ and $\delta_{Sm/Nd}$ for MORBs and OIBs are plotted in Fig 2. A δ-value of zero means that the sample falls on a 2-Gyr isochron through BE (bulk Earth). The $\delta_{Lu/Hf}$ of MORB is by far larger than zero, which is the hafnium paradox. Some recent process must be responsible for these large δ-values.

The high $\delta_{Sm/Nd}$ in OIBs (that is, that the Sm/Nd ratios do not support the measured $^{143}Nd/^{144}Nd$) was recognized early on[16], and this phenomenon was shown to be more pronounced in the Lu-Hf system, extending to MORBs as well as OIBs[5]. The high $\delta_{Sm/Nd}$ in OIBs is thought to be caused by either recent metasomatism or by extremely small amounts of melting of a garnet lherzolite[17]. For MORBs, metasomatism is a viable, though *ad hoc*, explanation for the low Sm/Nd and Lu/Hf in the basalts, we will consider the more likely case that melting has decreased Lu/Hf and Sm/Nd in MORBs, and has led to the observed $\delta_{Lu/Hf}$ and $\delta_{Sm/Nd}$.

We used the melting equation for equilibrium non-modal partial melting to calculate the trace-element ratios in the melt. We chose the proportions in which the phases enter the melt so that the melt was basaltic in composition. Our first conclusion is that simple one-stage melting models with anhydrous spinel lherzolite as a source material cannot account for the observed $\delta_{Lu/Hf}$ in MORBs, unless extremely small amounts of melt are extracted (<0.1%). The combined $\delta_{Sm/Nd}$ and $\delta_{Lu/Hf}$ systematics cannot be satisfied with any degree of melting in the spinel stability field, using either batch equilibrium melting or any of the more complicated melting models[1,18–22]. The Sm-Nd and Lu-Hf isotope systematics cannot be simultaneously satisfied even by using an extreme set of partition coefficients for clinopyroxene (increasing D_{Lu} so that $D_{Lu}/D_{Hf} > 3$, well above the experimental values).

A phase with D_{Lu}/D_{Hf} larger than clinopyroxene but with 'comparable' Ds for Sm and Nd is required. Garnet is such a phase, the relevant partition-coefficient ratios are $D_{Lu}/D_{Hf} = 23.9$ and $D_{Sm}/D_{Nd} = 4.3$ (for clinopyroxene $D_{Lu}/D_{Hf} = 1.55$ and $D_{Sm}/D_{Nd} = 1.60$). The garnet-melt distribution coefficients are from ref 23, and our unpublished data on garnet-diopside partitioning in garnet lherzolite xenoliths, equilibrated at 19–27 kbars, from Pali-Aike, Chile[24]. Garnet has an important role in OIB genesis, it has been proposed as a residual phase in MORB genesis[9,25,26] and as an important phase controlling the trace elements in alpine peridotites[27] and abyssal peridotites[26]. Amphibole is another phase that can change the K_ds appropriately. MORBs are undersaturated in H_2O, however, and thus amphibole cannot be a residual phase during the majority of the melting in MORB genesis.

In our melting model, which satisfies the Sm/Nd and Lu/Hf systematics, melting starts in the garnet stability field. In attempting to make the model as realistic as possible, we took the following observations into account. Recent calculations on melt extraction indicate that small amounts of melt (0.1–1%) are able to separate from the solid and ascend towards the surface[1]. We modelled this sequentially such that when a critical degree of melting (0.1–1%) is reached, this melt escapes and is accumulated at the top. The next batch is generated at shallower depth, with slightly different mineralogy (and mineral chemistry) and from a source already depleted by the previous melt extraction. Although this process is perhaps continuous, we treat it as a sequential batch process for numerical simplicity. Extracting melt only above a certain threshold, as in the critical melting model[21], would not substantially change the results.

The importance of the shape of the melting region has been stressed[18]. As the mantle material rises, the material at the ridge axis will end up higher than its neighbouring material that is somewhat off-axis[28]. Furthermore, the isotherm at the bottom of the plate is undisturbed and a ridge is not dynamically compensated[1,29]. Consequently, material directly under the ridge and material slightly off-axis will start melting at the same depth. The on-axis peridotite will rise to shallower depths and thus melt to a larger degree than the off-axis peridotite, which stops rising and 'turns the corner' at greater depth. In our model the melt generated off-axis is funnelled and collected at the centre. We assume that the decrease in degree of melting away from the ridge is linear[28,30] (see inset in Fig. 2 for further details).

Figure 2 illustrates the effect of garnet on the Sm/Nd and Lu/Hf ratios using the above equilibrium sequential batch melting model. Garnet is residual in the deeper part of the melting column. There are two useful ways (both shown in Fig. 2) to express the amount of melting in the garnet stability field: (1) the fraction of melt, of the total, that was generated in the garnet field, (2) the fraction of the on-axis melting column that lies in the garnet field. The degree of melting as seen at the surface is the average degree of melting and, because the shape of our melting region is linear, the average degree of melting is half the amount of on-axis melting. The middle of the MORB field in Fig. 2 can be reached with 10–15% melting on-axis, with one-fifth to one-third of the on-axis melting occurring in the garnet stability field. The low $\delta_{\mathrm{Sm/Nd}}$, high $\delta_{\mathrm{Lu/Hf}}$ MORBs can be generated by 15% of melting on-axis with one-third of the on-axis melt generated in the garnet field. Simpler melting models with residual garnet are also able to generate the observed variations, but smaller degrees of melting are required. Whatever melting model is chosen, some garnet is always required. Figure 2 also illustrates, as is commonly known, that many OIBs can only be generated by small degrees of melting, mostly in the garnet stability field.

Our model in Fig. 2 uses individual melt batches of 0.5%, and a garnet/diopside ratio of unity. If 0.1% of melt is allowed to escape, then slightly less on-axis melting is needed, 3–14%, to obtain the full range of $\delta_{\mathrm{Lu/Hf}}$ and $\delta_{\mathrm{Sm/Nd}}$ in MORBs. A maximum amount of on-axis melt (between 7–20%) can be obtained by extracting individual batches of 1%. The lower degrees of total melting needed with small (0.1%) individual batches is a consequence of the efficiency of this process, which effectively removes all the trace element from the residue.

The dynamic-melting model proposed by Langmuir *et al.*[20] (or the model proposed by Johnson *et al.*[26]) is also capable of explaining the $\delta_{\mathrm{Sm/Nd}}$ and $\delta_{\mathrm{Lu/Hf}}$, however smaller degrees of melting are necessary. The models proposed by McKenzie and Bickle[1], or Prinzhofer and Allègre[19] cannot generate the observed $\delta_{\mathrm{Sm/Nd}}$ and $\delta_{\mathrm{Lu/Hf}}$. The correlation between $\delta_{\mathrm{Lu/Hf}}$ and other indicators of degree of melting, such as $\mathrm{Na}_{8.0}$ (ref. 10), confirms the idea that $\delta_{\mathrm{Lu/Hf}}$ can be used as an indicator for the degree of melting. Furthermore, our estimates of the degree of melting, 5–17%, agrees with the estimates of Klein and Langmuir[10].

The onset of melting in the garnet stability field places the geotherm under the ridge on the solidus at 1,450 ± 50 °C at 80–90 km (refs 17, 31). This estimate is within the uncertainty of the Parsons and Sclater[32] estimate of 1,350 ± 275 °C at 125 km for the base of the lithosphere, but their estimate seems to be somewhat low. It is difficult to calculate whether the total amount of melt produced is realistic because the behaviour of the solidus as a function of melt depletion of the peridotite is not known. Experiments on peridotites[33] indicate an increase in the solidus by ≈50 °C for 20% batch melting of a fertile peridotite, this is a minimum estimate for a sequentially melted source. Assuming the increase in the solidus is 75 °C and using heat-of-fusion data from ref. 34, then the magma reaches 1,300–1,320 °C at 20-km depth with 15% of adiabatic batch melting. Assuming the onset of melting at 90-km depth, then the relatively large degree of melting in the garnet stability field can be explained by the effect of increased amounts of melt generated at a cusp of the solidus[35] related to the garnet–spinel transition. Although more knowledge of the solidus of depleted peridotite is necessary to test our model fully, our conclusions are consistent with the limited information derived from experimental data.

The $\delta_{\mathrm{Lu/Hf}}$ and $\delta_{\mathrm{Sm/Nd}}$ calculated above assumed a depletion age of 2 Gyr for the MORB mantle. However, an average residence time of 600 Myr for some trace elements in the MORB

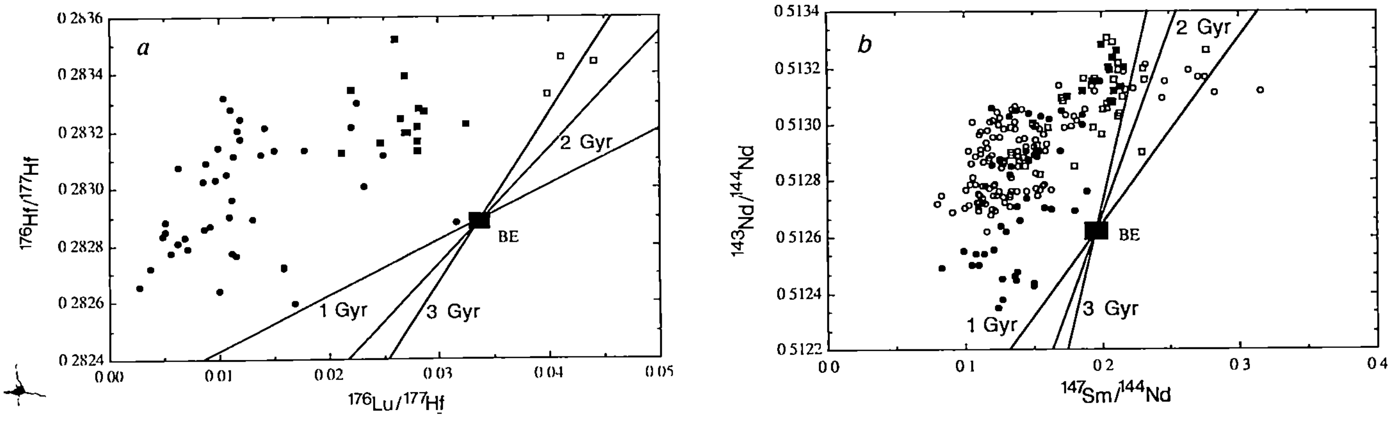

FIG. 1 *a*, $^{176}\mathrm{Hf}/^{177}\mathrm{Hf}$ plotted against $^{176}\mathrm{Lu}/^{177}\mathrm{Hf}$ and *b*, $^{143}\mathrm{Nd}/^{144}\mathrm{Nd}$ plotted against $^{147}\mathrm{Sm}/^{144}\mathrm{Nd}$ for oceanic volcanics. Squares are MORBs and circles are OIBs. Solid symbols are for those samples where both the Lu-Hf and Sm-Nd systematics are known. The 1-, 2- and 3-Gyr lines are isochrons through BE (bulk Earth). The geochron is a near-vertical line through BE (not shown). Samples falling to the left of the isochrons must have undergone a recent decrease in parent/daughter ratio. Data from refs 5, 6, 37 and references therein, W. M. White, unpublished data, and MIT, unpublished data. Bulk Earth Lu/Hf from ref. 38 and C1 (or BE) $^{176}\mathrm{Hf}/^{177}\mathrm{Hf}$ from ref. 6.

Any mantle model[1-4] includes significant amounts of both CaO and Al_2O_3, in addition to SiO_2, MgO and FeO. From high-pressure experiments performed on simple chemical systems, it has been suggested that, in the deep mantle, calcium is found in a $CaSiO_3$ perovskite[5,6], with aluminium in an Al-bearing perovskite[7,8]. Several experiments with more complex chemical systems have shown, however, that other aluminocalcic high-pressure phases could be formed. For instance, a CaO-rich phase and an Al_2O_3-rich phase have been observed in experiments performed at 27 GPa and 1,600 °C, the composition of the starting material being close to the olivine-subtracted peridotitic mantle composition[9,10]. Owing to the small grain size, the exact composition and the structure of these new phases are unknown.

To identify such aluminocalcic high-pressure phases, we have transformed a natural garnet in a laser-heated diamond-anvil cell. The starting material was a xenocryst, from Moses Rock (Arizona), with a composition close to $(M_{0.88}, Ca_{0.12})_3Al_2Si_3O_{12}$ where M corresponds to divalent cations Mg, Fe and Mn (see Table 1). The starting material was crushed in an agate mortar, and the powder was loaded in the hole of a nickel gasket. Samples were then brought to ~50(±5) GPa, as determined with a strain gauge[11], and heated by scanning the beam of a Nd YAG laser across the sample. After heating, the quenched products were ion-beam thinned and observed with a Jeol 2000 EX electron microscope equipped with a Tracor TN 5400 FX analytical attachment. The transformed materials were identified by electron diffraction and/or microanalysis. All experimental procedures, and especially the precision of chemical analysis, are described elsewhere[11,12].

In all samples, observations by transmission electron microscope (TEM) show the coexistence of two phases. The first is perfectly stable under the electron beam, and it is found in contact with another phase that amorphizes quickly under the electron beam (Fig. 1*a*). The electron diffraction patterns taken on this latter phase before amorphization are compatible with the structure of orthorombic perovskite[13], but those obtained on the stable phase are new: they do not correspond to a classical high-pressure structure such as perovskite. The composition of the two phases, given by *in situ* X-ray microanalysis, are close to $(M_{0.78}, Ca_{0.03}, Al_{0.19})(Si_{0.81}, Al_{0.19})O_3$ for the perovskite phase and $(M_{0.5}, Ca_{0.5})Al_2Si_2O_8$ for the other phase. The composition of the starting material and those of the final products (Table 1), indicate that the decomposition of garnet must also lead to the formation of a magnesiowüstite, according to the reaction:

$$(M_{0.88}, Ca_{0.12})_3Al_2Si_3O_{12} \rightarrow (4-3x)\cdot(M_{0.78}, Ca_{0.03}, Al_{0.19})(Si_{0.81}, Al_{0.19})O_3 + x\cdot(M_{0.5}, Ca_{0.5})Al_2Si_2O_8 + x\cdot MO$$

where x is a factor depending of the initial content of calcium in the starting material. In our experiments $(Ca/Ca+M=0.12)$, $x=0.557$.

No magnesiowüstite was observed in the samples, but this could be due to the small amount of this phase formed during the decomposition of garnet into post-garnet phases. Indeed, from the molar volume of each component, ~6% of magnesiowüstite should be formed in the previous reaction, for 56% of perovskite and 38% of the new phase. The relative proportions of perovskite and new phase observed in the transformation products of garnet are in good agreement with these values.

No $CaSiO_3$ perovskite was observed in the transformation products of garnet. We conclude that this phase cannot be formed at high pressure (at least at 50 GPa), when the three types of cations—calcium, aluminium and magnesium (or iron)—exist simultaneously in the starting material.

To see if a change in the chemical composition of the starting material leads to the same aluminocalcic phase, and to determine

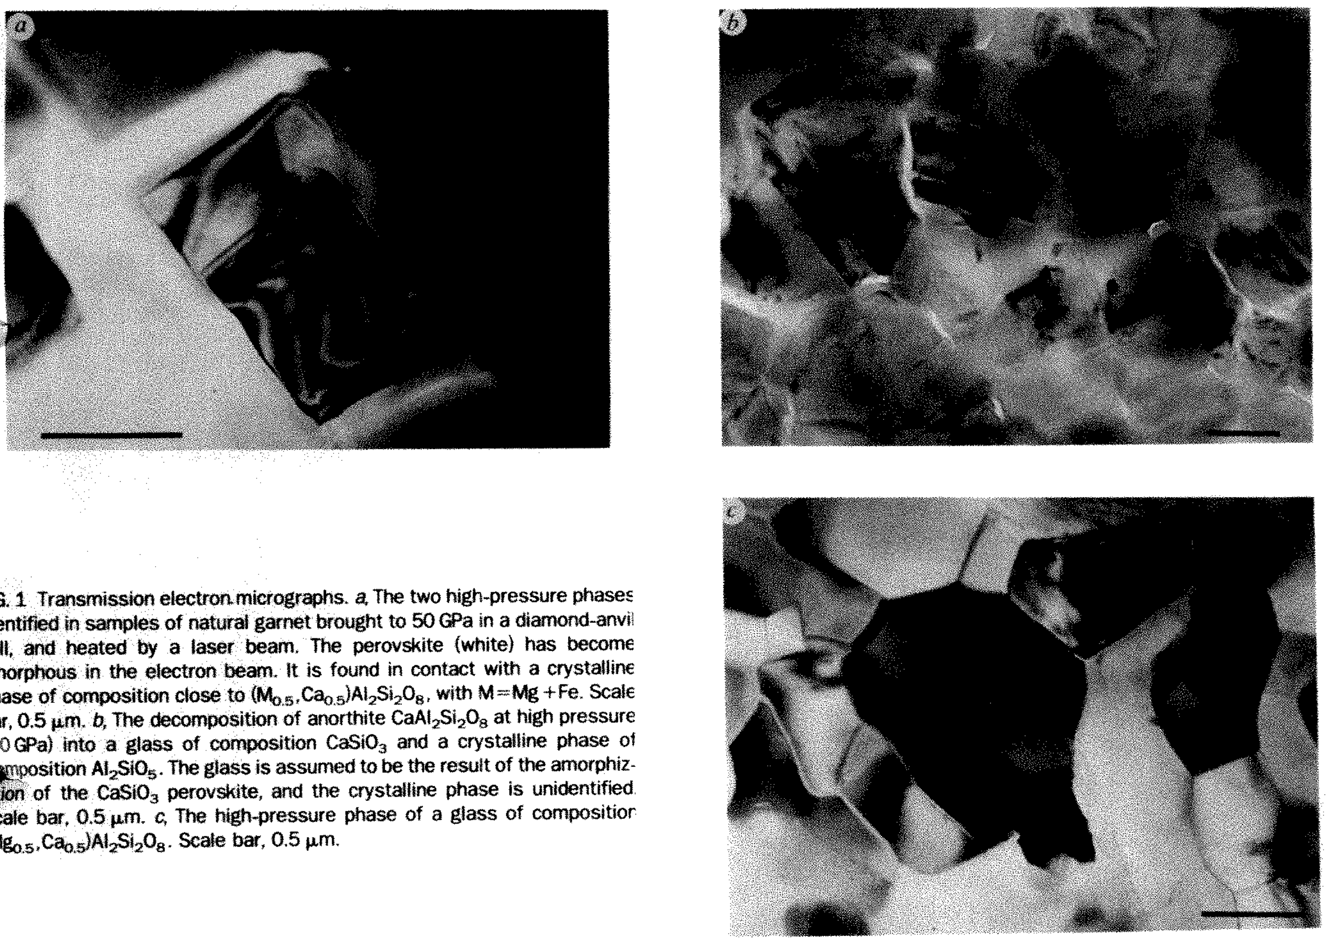

FIG. 1 Transmission electron micrographs. *a*, The two high-pressure phases identified in samples of natural garnet brought to 50 GPa in a diamond-anvil cell, and heated by a laser beam. The perovskite (white) has become amorphous in the electron beam. It is found in contact with a crystalline phase of composition close to $(M_{0.5}, Ca_{0.5})Al_2Si_2O_8$, with M = Mg + Fe. Scale bar, 0.5 μm. *b*, The decomposition of anorthite $CaAl_2Si_2O_8$ at high pressure (50 GPa) into a glass of composition $CaSiO_3$ and a crystalline phase of composition Al_2SiO_5. The glass is assumed to be the result of the amorphization of the $CaSiO_3$ perovskite, and the crystalline phase is unidentified. Scale bar, 0.5 μm. *c*, The high-pressure phase of a glass of composition $(Mg_{0.5}, Ca_{0.5})Al_2Si_2O_8$. Scale bar, 0.5 μm.

the cell parameters, we performed additional runs with two glasses as starting materials. The first glass had the composition of anorthite [$CaAl_2Si_2O_8$] and the second glass, the same composition with half atoms of magnesium in substitution of atoms of calcium [$(Ca_{0.5},Mg_{0.5})Al_2Si_2O_8$]; the latter composition is very close to that described in the previous section. The finely powdered glasses, mixed with a trace amount of platinum to absorb the laser radiation, were compressed and heated in the diamond-anvil cell at the same (P, T) conditions than those previously described. The TEM observations of the transformation products of two glasses lead to the following comments: (1) At high pressure, $CaAl_2Si_2O_8$ decomposes in two phases, a glass of composition $CaSiO_3$, in contact with another crystalline phase of composition Al_2SiO_5 (Fig. 1*b*). The amorphous $CaSiO_3$ phase is assumed to be the result of the amorphization of $CaSiO_3$ perovskite at room pressure, as generally observed[14], and the crystalline Al_2SiO_5 phase is unidentified, but the electron diffraction patterns disagree with the kyanite structure; (2) The experiments done with the second glass confirm the existence of a crystalline phase of $(Ca_{0.5},Mg_{0.5})Al_2Si_2O_8$ composition, at 50 GPa (Fig. 1*c*). These experiments confirm the stability of the $CaSiO_3$ perovskite at high pressure when two types of cations (Ca and Al) exist in the starting material, but also show that another high-pressure phase is preferred when the three cations (Ca, Al and Mg or Fe) are simultaneously present in the sample.

The cell parameters of the new phase were identified from powder X-ray diffraction patterns obtained with a 180-mm Debye–Scherrer camera. X-ray diffraction data for a glass sample of $(Ca_{0.5},Mg_{0.5})Al_2Si_2O_8$, quenched from ~50 GPa, are listed in Table 2. The unit-cell dimensions were determined to be $a = 9.384$, $b = 8.148$ and $c = 9.258$ Å, with $\beta = 90.474°$. The molar volume and the density of the new phase calculated for $Z = 6$, are $71.06 \pm 0.04\ cm^3\ mol^{-1}$ and $3.804 \pm 0.002\ g\ cm^{-3}$ respectively, at room temperature and pressure. This phase is very similar to the hollandite structure. First, the molar volume and the density are similar to those of $NaAlSi_3O_8$ hollandite[1] ($V = 71.0\ cm^3\ mol^{-1}$, $\rho = 3.69\ g\ cm^{-3}$) and $KAlSi_3O_8$ hollandite[16] ($V = 72.6\ cm^3\ mol^{-1}$, $\rho = 3.84\ g\ cm^{-3}$). Second, the composition of the (Ca,Mg) phase conforms to the general formula $[A_x][B_y,C_{4-y}]O_8$ of the hollandite structure family where the A cations may be monovalent or divalent, where the smaller cations making up the octahedral $[B,C]_4O_8$ framework include tri- and tetravalent species[17]. Third, the lattice parameters are very close to those of the distorded hollandite structure. The ideal hollandite unit cell is tetragonal, with a value of the '*c*' axis ~2.8 Å. This value represents the edge-to-edge dimension of a $[B,C]O_6$ octahedra. Yet, depending on the chemistry of the sample, the *c* axis can be a multiple of the ideal value. This is the case in many barium titanate hollandites where a deficiency in stoichiometry leads to a multiplicity of the *c* axis[18]. On the other hand, many hollandites show a small distortion that lowers the symmetry from the tetragonal to the monoclinic structure, with a value of $\beta \sim 90°$ (refs 19, 20). In our experiments the aluminocalcic phase seems to adopt such a distorted hollandite structure, that is a monoclinic structure ($\beta = 90.474°$) with a multiplicity of the *b* axis (equivalent to the *c* axis of the ideal structure) close to three. But two points disagree with this interpretation. First, the multiplicity of the *b* axis is not easily explained because the (Ca,Mg) phase seems to be stoichiometric. Second, the intensities of the diffraction lines (Table 2) are not in good agreement with those of the ideal hollandite structure. Further work is needed to resolve the issue.

The density of the $(Ca_{0.5},Mg_{0.5})Al_2Si_2O_8$ phase seems to be low at room pressure ($\rho = 3.804\ g\ cm^{-3}$) with respect to the densities of other high-pressure phases such as $MgSiO_3$

perovskite[21,22]($\rho = 4.11$ g cm^{-3}), or $CaSiO_3$ perovskite[23,24]($\rho = 4.24$ g cm^{-3}). As $(Ca_{0.5}, Mg_{0.5})Al_2Si_2O_8$ forms at 50 GPa along with the magnesian perovskite, we can expect that its density is similar to that of perovskite $MgSiO_3$ (or $CaSiO_3$) at the same pressure. At 50 Gpa and room temperature, the perovskite densisities are ~4.9 g cm^{-3}. To obtain the same density at the same pressure, the $(Ca_{0.5}, Mg_{0.5})Al_2Si_2O_8$ phase should have a bulk modulus of ~120 GPa with the commonly made assumption ($K'_0 = 4$) for the first derivative of K_0 at 1 bar. We note that this value is low in comparison with those of perovskites ($K_0 = 247$ GPa in $MgSiO_3$ perovskite[22] and 268 GPa in $CaSiO_3$ perovskite[24]), but of the same order of magnitude as other compounds such as wüstite MgO (ref. 25) ($K_0 = 154$ GPa) or CaO (ref. 26) ($K_0 = 111$ GPa). Another explanation for the low value of the density of the aluminocalcic phase at room pressure could be a phase change of this compound at higher pressure—indeed, a reversible transition (similar to the B1-B2 transition occuring in the CaO compound at ~60 or 70 GPa (ref. 26) could lead the $(Ca_{0.5}, Mg_{0.5})Al_2Si_2O_8$ phase to a density similar to those of perovskites at high pressure and to a low density at room pressure.

We have started static measurements of the compression of the $(Ca_{0.5}, Mg_{0.5})Al_2Si_2O_8$ phase in a diamond-anvil cell to determine its high-pressure density and look for a possible phase transition.

These observations show that an aluminocalcic phase with a composition $[(Ca_{0.5}, Mg_{0.5})Al_2Si_2O_8]$ close to but different from that of anorthite, can accommodate the calcium at high pressure. We suggest that this phase could be the crystalline host for not only the calcium in the lower mantle, but also for the other large cations such as sodium, potassium or the radioactive elements. This phase could be an important constituent of the lower mantle. Depending on the assumed mantle composition, this phase is inferred to be the second or the third most abundant constituent of the lower mantle, with the perovskite and the magnesiowüstite (Table 3). Indeed, assuming that all the aluminium reacts with the calcium to form an aluminocalcic phase of the above composition, and that the solubility of the $CaSiO_3$ molecule in $MgSiO_3$ orthorhombic perovskite is ~3%, the proportion of the (Ca,Mg)-phase, in volumetric ratio, would vary from 6% to 25% of the lower mantle. As a result, the abundance of $CaSiO_3$ perovskite in the lower mantle would be negligible. □

Discovery of the earliest-known tetrapod stapes

J. A. Clack

University Museum of Zoology, University of Cambridge, Downing Street,
Cambridge CB2 3EJ, UK

THE evolution of the middle ear is central to the discussion of how the first tetrapods adapted to life on land as well as their phylogeny[1–3]. Here I report the discovery of the stapes of *Acanthostega gunnari*, from the Upper Devonian of east Greenland. This is the earliest tetrapod stapes so far described, and it throws new light on both these aspects of early tetrapod biology. It has been assumed that the common inheritance of all early tetrapods was a light, rod-like stapes associated with a temporal notch in the otic region that was thought to have supported a tympanum, or eardrum. The stapes would have conducted vibrations from the tympanum to the otic capsule. By contrast, the stapes of *Acanthostega* was stout with a broad distal ramus associated with the temporal notch. I suggest that the temporal notch of *Acanthostega* and other early tetrapods supported a spiracular opening rather than a tympanum, and that the stapes controlled palatal and spiracular movements in ventilation.

Of six *Acanthostega* stapes collected by a Cambridge-Copenhagen expedition to east Greenland (Figs. 1, 2; ref. 4), four are preserved approximately in life-position. This indicates that the stapes was firmly held in place in life, despite the incomplete ossification of the otic region of the braincase into which the footplate of the stapes was presumably inserted. The footplate, the medial surface of the stapedial head, is large. Only one head

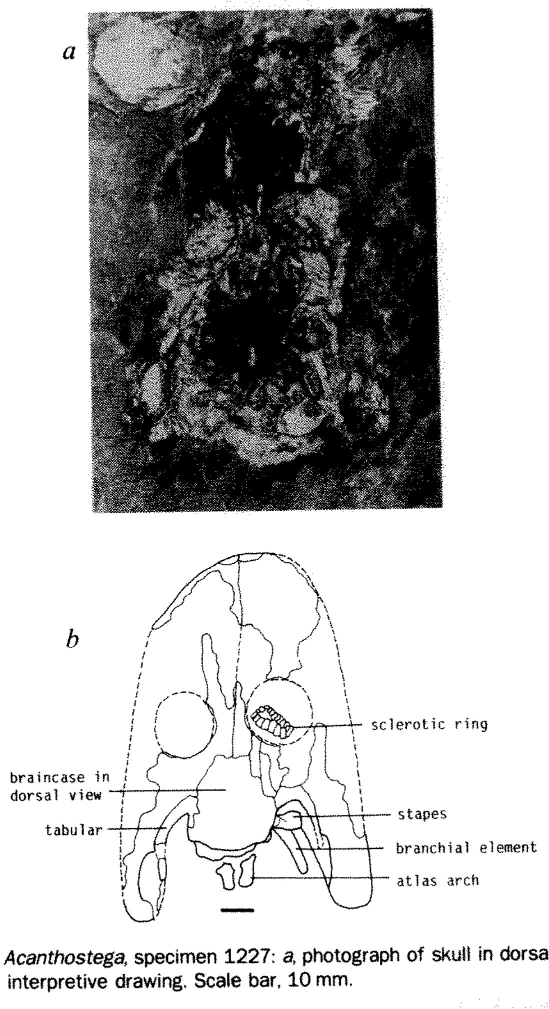

FIG. 1 *Acanthostega*, specimen 1227: *a*, photograph of skull in dorsal view with *b*, interpretive drawing. Scale bar, 10 mm.

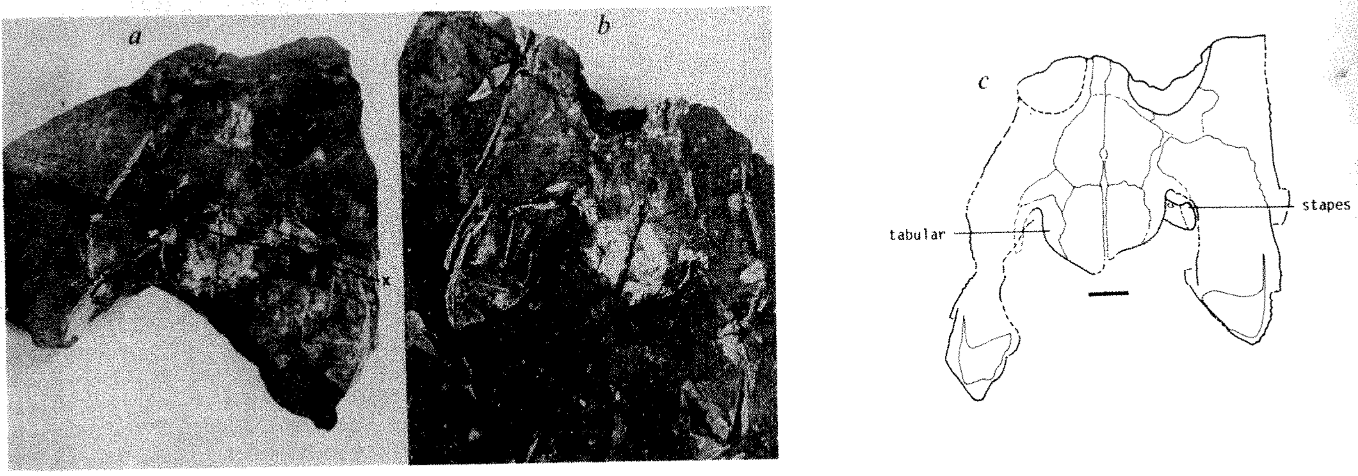

FIG. 2 *Acanthostega*, specimen 1604: *a*, partial skull in dorsal view showing proximal end of stapes; *b*, counterpart skull roof showing distal end of stapes; *c*, interpretive drawing with stapes drawn from part and counterpart of specimen. Scale bar, 10 mm.

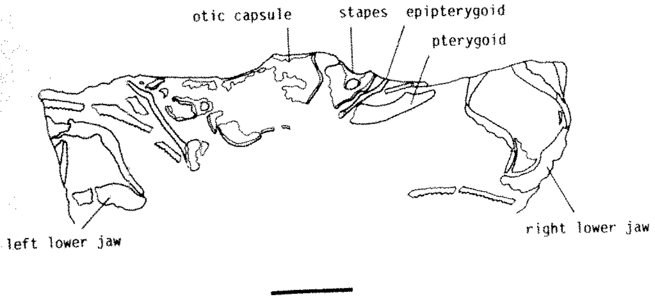

FIG. 3 *Acanthostega*, specimen 1604: drawing of section at X (see Fig. 2), showing stapes, palatal bones and lower jaws. Scale bar, 10 mm.

is apparent in vertical section, although this cannot be confirmed in the surface-prepared material, because the footplate is obscured (Figs. 3 and 4). A robust neck region separates the head from the shaft. Proximally, the head abuts the otic capsule, and the distal margin of the fan-shaped ramus, which has cartilage-finished lateral and posterior margins, extends laterally towards the well-developed temporal notch bordered by the tabular bone (Fig. 4). Temporal notches are often described as 'otic' with the presumption that each held a tympanum. Their occurrence in the earliest tetrapods has been equated with presence of a tympanum in these animals.

The massive, expanded stapes of *Acanthostega* is strikingly similar to those of two unrelated Carboniferous tetrapods, although it is much older[5,6]: *Greererpeton*, a colosteid, lacks a temporal notch[5,7], whereas *Pholiderpeton*, an embolomere, has a narrow, wedge-shaped notch (Fig. 4). The apparent absence of a tympanic ear in these Carboniferous forms could have been a convergent loss related to a secondarily aquatic lifestyle[6]. But the stapedial morphology of *Acanthostega* indicates that it too lacked a tympanic ear, though it possessed a notch. Absence of a tympanum now appears primitive for tetrapods; its presence could only reasonably be inferred if a temporal notch were associated with a relatively light, rod-like stapes. However, even in the absence of a tympanum, the stapes is likely to have had some auditory function because of the close association between the footplate and the otic capsule[8].

Carroll[7] suggested that the stapes of *Greererpeton* braced the braincase against the cheek, representing the primitive tetrapod condition in which the occiput, braincase and skull roof were not fully integrated. But the braincase and skull roof were intimately connected in both *Pholiderpeton*[9] and *Acanthostega*[10], so that a bracing function for the stapes is unlikely in these animals. I suggest instead that the stapes of primitive tetrapods was actively involved in ventilation, as was its homologue, the hyomandibula of fishes.

In many fossil fishes, including the osteolepiforms usually regarded as the closest relatives of tetrapods, the hyomandibula contributed to the suspension of the lower jaw and supported the back of the palate. By analogy with living fishes, it acted as

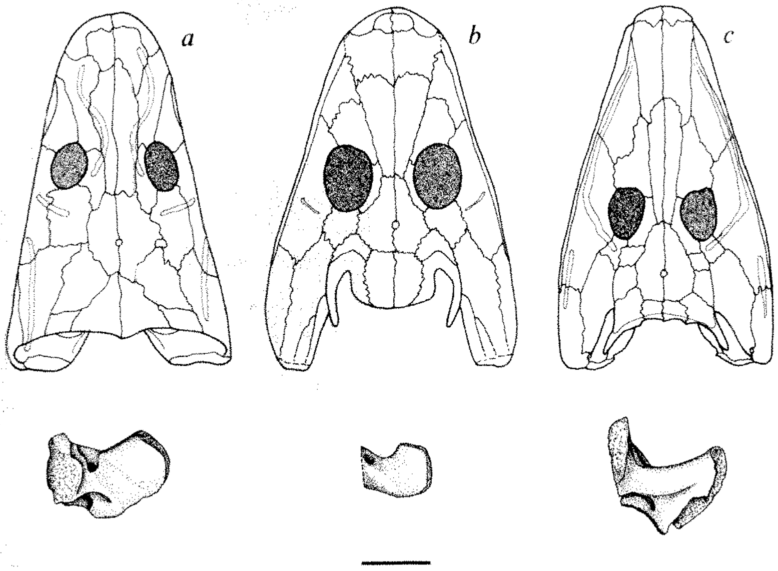

FIG. 4 Skulls and stapes of early tetrapods: *a*, *Greererpeton* (snout to quadrate length 131 mm), stapes in dorsal view below; *b*, *Acanthostega* (snout to quadrate length 115 mm), restoration of stapes from specimens 1227 and 1604 in approximately dorsal view below; *c*, *Pholiderpeton* (snout to quadrate length 320 mm), stapes in approximately dorsal view below. Scale bar (for stapes only), 10 mm.

a hinge coordinating kinetic movements of the palate and cheek used to ventilate the gills and in feeding. A similar buccal pumping mechanism is used to ventilate both lungs and gills in those fishes that have lungs[11]. These movements are controlled by muscles attached to the palate and hyomandibula, and in the modern but primitive actinopterygian *Polypterus*, these muscles also control the operation of an open spiracle[12].

The earliest tetrapods may have retained a fish-like breathing mechanism. In *Acanthostega* and other primitive tetrapods the palate and braincase were connected by a synovial joint[9,13] allowing a degree of intracranial mobility. The temporal notch in some primitive tetrapods may have housed an open spiracle homologous with the spiracular notch of the earliest bony fishes[14]. The spiracle in tetrapods could have been used for inspiration when the rest of the animal's head was submerged. The spiracular cleft and stapes could also have contributed to an underwater hearing mechanism[15]. Associated with intracranial mobility and an open spiracle, the stapes in early tetrapods might thus have retained a function more directly comparable with that of the fish hyomandibula, in that it controlled palatal and spiracular movements during breathing.

The close morphological similarities between the stapes of three otherwise distantly related tetrapods indicates that the massive stapes is a tetrapod autopomorphy, derived with respect to that of any non-tetrapod outgroup, but nonetheless primitive. Other forms, including the rod-like type found in tympanic ears, were later derivations. Alternatively, the massive stapes could be a synapomorphy uniting 'labyrinthodonts'[3], not otherwise considered to be a natural group[16]. The relationship of *Acanthostega* to any 'labyrinthodont' is not yet supported by other synapomorphies. It has recently been suggested that possession of a double-headed stapes was the primitive tetrapod condition, comparable with the double-headed hyomandibula seen in osteolepiform fishes, and the stapes of many early reptiles[17]. This view would be corroborated by finds of double-headed stapes in the earliest tetrapods, but is not supported so far by the condition actually found in those where it is known. ☐

Ocular dominance plasticity in adult cat visual cortex after transplantation of cultured astrocytes

Christian M. Müller & Johannes Best*

Max-Planck-Institut für Hirnforschung, Deutschordenstrasse 46,
D-6000 Frankfurt Main 71, FRG

DURING a critical restricted period of postnatal development, the visual cortical circuitry is susceptible to modifications that are dependent on experience[1]. If vision is restricted to only one eye during this period, the territories innervated by the deprived eye shrink considerably, whereas those innervated by the non-deprived eye expand, and the deprived eye loses the ability to influence almost all of the cells in the cortex[2,3]. Thus, changes in ocular dominance are paralleled and possibly mediated by synapse elimination and axonal sprouting. Hypotheses about the mechanisms underlying ocular-dominance plasticity assume the activation of NMDA (*N*-methyl-D-aspartate) receptors and subsequent calcium influx as a trigger of synaptic modifications[1,4,5]. In addition, plasticity relies on functional neuromodulatory afferents[6,7]. On the basis of immunocytochemical studies, it was recently proposed that the presence of immature astrocytes is a prerequisite for visual cortical plasticity, and that the end of the critical period is causally linked to the maturation of astrocytes[8,9]. Here we report, in support of this hypothesis, that resupplementation of the visual cortex of adult cats with astrocytes cultured from the visual cortex of newborn kittens reinduces ocular-dominance plasticity in adult animals.

The study described here was designed to test the hypothesis that the presence of immature astrocytes is a prerequisite for ocular dominance (OD) plasticity by transplanting astrocytes cultured from newborn kittens into the visual cortices of five adult cats (Fig. 1). These animals were at least one year old and had therefore passed the critical period for cortical plasticity (for a review see ref. 1). Controls included animals ($N = 2$) that each received a transplantation of fibroblasts (the chief contaminant of the astrocytic cultures) in one hemisphere. In addition, every animal received a transplantation of cells destroyed by repeated freezing in the hemisphere contralateral to the one transplanted with intact cells. After 4-8 weeks of monocular deprivation, which began at the time of transplantation, animals were reanaesthetized and the OD distribution assessed using standard electrophysiological techniques. To avoid a bias caused by preferential recording within certain OD columns, electrode tracks were aimed in an oblique direction in the cortex. Recording tracks were placed at the lateral coordinates where the transplants had been performed. For each cell we determined the OD (five-class scale) and the response strength (four-class scale) by presenting optimally oriented, moving light-bars with a hand lamp on a tangent screen.

The mean response strengths observed in the experimental hemispheres (transplanted with intact cells) and the control hemispheres (transplanted with cells frozen before transplantation) do not differ significantly from one another (control: 2.98 ± 0.67, $N = 321$; experimental: 3.00 ± 0.65, $N = 548$). Significant differences in the OD distributions exist between experimental and control hemispheres, however. The OD distributions of the control hemispheres that received a transplantation of cells destroyed by multiple freezing showed a contralateral bias typical for normally raised adult cats[10,11]. Most cells were driven by stimulation of either eye, and the OD distribution showed a moderate bias towards the contralateral eye (Fig. 2; far-left histogram, control). This bias occurred irrespective of whether the ipsilateral- or contralateral eye was closed during the period of monocular deprivation as a result of suturing (see Fig. 3 for data from individual animals). By contrast, the hemispheres that received intact astrocyte suspension showed OD distributions always biased towards the non deprived eye. In cases in which

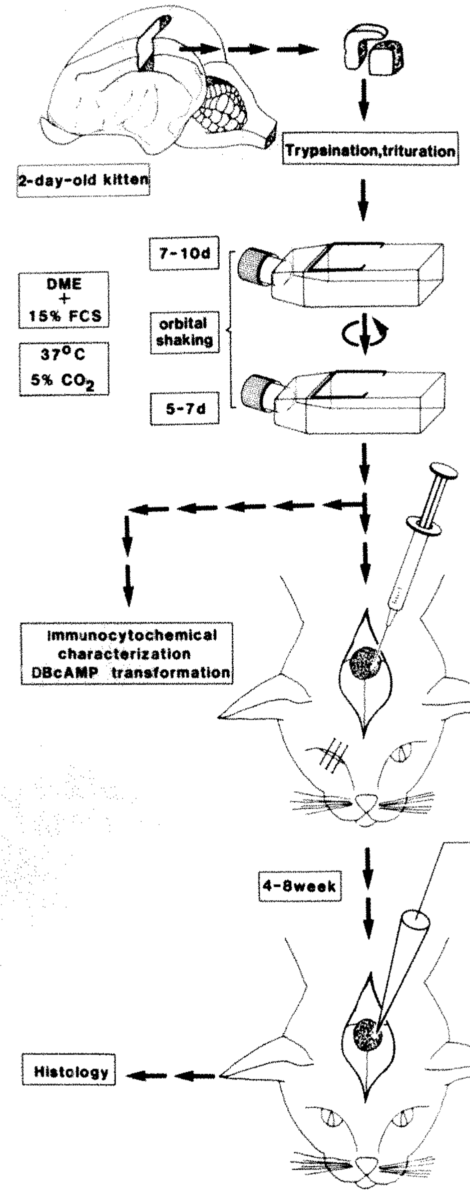

FIG. 1 Schematic representation of the experimental paradigm. Astrocytic cultures were prepared from the visual cortex of newborn kittens and injected as a cell suspension into the visual cortex of adult cats. At the same time one eye was sutured close. After a period of 4–8 weeks the OD distribution in the hemispheres was assessed by electrophysiological recording.
METHODS. Glial cultures were prepared from 2-day-old kittens. After decapitation, a block of visual cortex was removed, cleared of meningeal tissue and white matter, and minced in small pieces by use of two scalpel blades. After preincubation in Ca^{2+}- and Mg^{2+}-free phosphate buffer (CMF, 37 °C, 10 min), the tissue was transferred to a trypsin solution (1% in CMF, 37 °C, 10 min). After three washes with Dulbecco modified Eagles medium containing 10% fetal calf serum, the tissue was triturated with a fire-polished glass pipette (10 strokes) and seeded in precoated culture flasks (Primaria, 25 cm^2) at a density of 30,000 cells cm^{-2}. The culturing medium (DMEM, 10–15% FCS) was changed every second day. Contaminating oligodendrocytes were removed by orbital shaking[28] at day 7–10. Fibroblast cultures were prepared from meningeal tissue under identical culturing conditions. When cultures had again reached confluency, cells were collected either by mild trypsinization or by mechanical scraping, centrifuged and resuspended in 40 μl CMF. Part of the cultures were reseeded on glass coverslips, and the astrocytic nature of the cells was reconfirmed by immunostaining with the astroglial markers vimentin, S-100 and GFAP, in addition to testing the ability of dibutyryl cyclic AMP to transform the cells into process-bearing stellate cells. Quantification of the cultures revealed that 94% (±4%) of the cells were immunoreactive for both GFAP and vimentin and transformed into stellate cells after dibutyryl cAMP. The remaining cells were immunoreactive for vimentin only. Most of these cells had a flat morphology even after 24 h of treatment with dibutyryl cAMP and, thus, resembled fibroblasts. A few small cells containing vacuoles and resembling macrophages were encountered in astrocyte-enriched, as well as in fibroblast cultures. After collecting the cell suspension was immediately injected into the visual cortex of anaesthetized adult cats mounted in a stereotaxic frame. One hemisphere received a total of 10–20 μl (2–8 injection sites) of intact cell suspsension, and the other was injected with the same amount of cell suspension frozen and thawed three times. Transplants were placed on the top of the gyrus suprasplenius at antero-posterior coordinates −5 to +2. After cell transplantation, one eyelid was sutured closed. The animals received antibiotic treatment for three days. After a period of 4–8 weeks of monocular deprivation, the animals were reanaesthetized, and the OD distribution in the cortices was assessed by standard electrophysiological techniques, using laquer-insulated tungsten electrodes. After termination of the experiments, animals were perfused with fixative, and frozen sections were prepared for reconstruction of penetration tracks, using small electrolytic lesions as references.

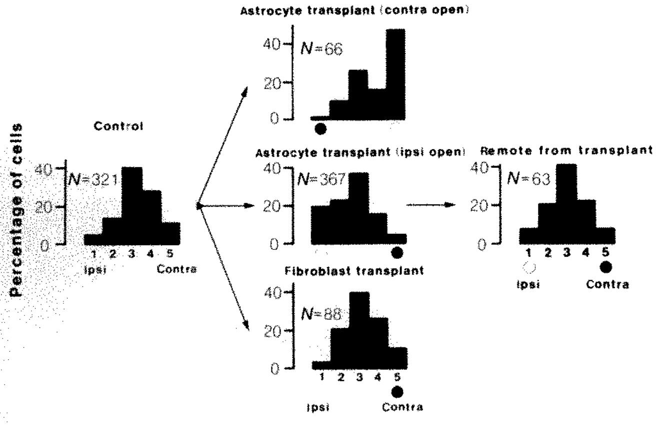

FIG. 2 OD histograms composed from data from seven cats. Monocular cells responding exclusively to stimulation of one eye are categorized in class 1 (driven by ipsilateral eye) or class 5 (driven by contralateral eye). Classes 2 and 4 represent binocular cells in which one eye was dominant. Class 3 represents cells responding equally well to stimulation of either eye. Histograms from the control hemispheres of all seven cats (far-left histogram, control) reveal a moderate bias towards the contralateral eye. The middle OD histograms were obtained from transplanted hemispheres. Combining astrocyte transplantation with deprivation of the ipsilateral eye resulted in an increased occurrence of cells driven exclusively by the experienced contralateral eye (class 5, top histogram, contra open). The central OD (ipsi open) was obtained from the astrocyte-transplanted hemisphere of four cats in which the contralateral eye was sutured closed. Note the bias towards the nondeprived ipsilateral eye. This effect was not present when recordings were obtained from locations remote from the transplantation site (far-right histogram, composite data from two animals). The bottom histogram shows data from two cats that received a transplantation of fibroblasts instead of astrocytes; the OD distribution does not differ from that obtained from control hemispheres. ○, Eye open; ●, eye closed.

the contralateral eye was closed, there is an ipsilateral dominance, whereas in one animal in which the ipsilateral eye was deprived, an overproportional number of cells were responsive only to contralateral stimulation (OD class 5; see Figs 2 and 3). The differences between the OD distributions of the control hemispheres and the astrocyte-receiving hemispheres are highly significant (χ^2 test, 4 degrees of freedom) in each cat that received an astrocyte transplantation (see Fig. 3 legend).

In addition to the control in which destroyed cells were injected into one hemisphere, two further controls were performed. First, the regional specificity of the effect of astrocyte transplantation was assessed by recording cells within the transplanted hemisphere of two animals, just 1 mm lateral to the transplant. This OD histogram does not differ significantly from the one obtained in the control hemisphere (Fig. 2). The local specificity was further detailed by separating cells recorded

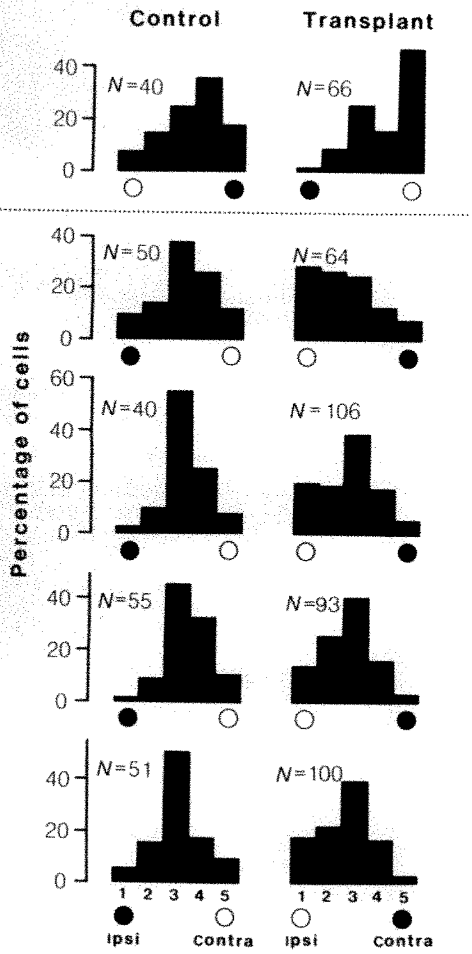

FIG. 3 OD histograms from visual cortex of all five monocularly deprived adult cats that received transplantation of cultured astrocytes. In the control hemispheres (left column), which received previously frozen cell suspension, OD histograms reflect a moderate bias towards the contralateral eye, irrespective of whether this eye was open or closed during the deprivation period (○, open; ●, closed). By contrast, in hemispheres that received intact astrocyte transplantation, OD histograms are always biased towards the open eye. This results in an overproportional presence of contralaterally dominated cells when the ipsilateral eye was sutured closed (row 1), and vice versa (rows 2–5). The overall differences in the OD histograms from the experimental and control hemispheres are statistically significant when tested with the χ^2 test. Calculated significances for each animal from top to bottom are: (1) $\chi^2=28.97$, $P<0.001$; (2) $\chi^2=20.60$, $P<0.001$; (3) $\chi^2=12.23$, $P<0.01$; (4) $\chi^2=31.52$, $P<0.001$; (5) $\chi^2=14.50$, $P<0.01$.

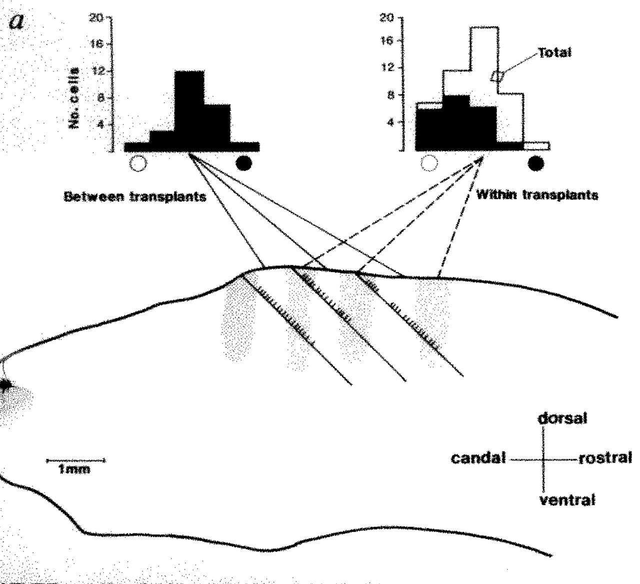

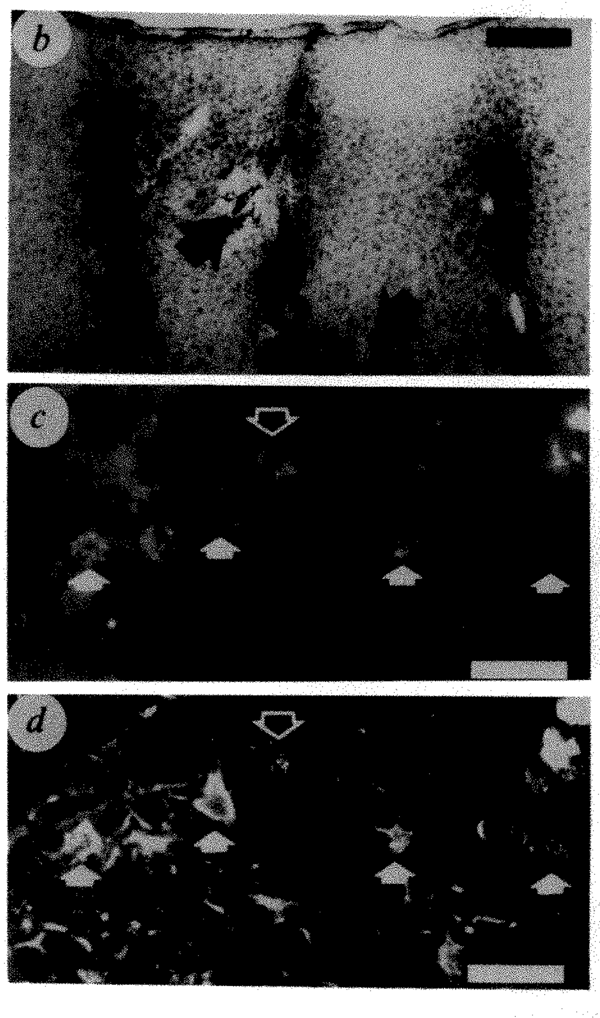

FIG. 4 *a*, OD histograms for cells recorded along the three penetrations passing through locations where transplanted astrocytes were present (dotted). Cells located on the border of the transplants ($N=7$) and two unresponsive units were omitted. OD histograms for cells recorded outside the transplants show a moderate bias towards the contralateral (deprived) eye, whereas a clear bias towards the (experienced) ipsilateral eye is seen in the OD distribution from cells recorded within transplanted regions. The composite histogram of the entire sample of cells given by the open columns in the right histogram continues to show a moderate bias towards the non-deprived eye. *b*, Low-power photomicrograph of the section drawn in *a*, stained with a monoclonal antibody directed against GFAP. Intense immunostaining is present at the sites of astrocytic transplants. The three transplantation sites correspond to rostral transplants in a. Two electrolytic lesions (arrows) mark an electrode track passing through the central transplantation site. *c*, *d*, Higher-power photomicrographs from the border region of an astrocyte transplant viewed with a fluorescent microscope. Transplanted cells were identified by the presence of rhodamine-labelled latex microspheres (*c*); the astrocytic nature of these cells was shown by the presence of GFAP-immunoreactivity (*d*). Note that most rhodamine-labelled cells also display GFAP immunoreactivity (for example, those marked by closed arrows in *c* and *d*). A subpopulation of cells containing rhodamine-labelled particles (open arrow in *c* and *d*) are not GFAP positive and thus may correspond to non-astrocytic cells such as fibroblasts or macrophages. Scale bars: *b*, 500 μm; *c* and *d*, 25 μm.

METHODS. *a*, The location of the transplants was made visible by the presence of cells prelabelled with rhodamine-coupled microspheres fed to the astrocytic cultures (10 μl per 7 ml culture medium; 12 h) before transplantation (see *c*, *d*). Electrode tracks were reconstructed using electrolytic lesions as references (see *b*). *b*, Vibratome sections (50 μm) were incubated with a monoclonal antibody directed against GFAP (Boehringer). Antigen-locations were visualized using the Avidin–biotin method with diaminobenzidine as the chromogen[8]. *c*, *d*, For concurrent visualization of fluorescent latex microspheres, fed to the astrocytic cultures before transplantation, and GFAP, sections were incubated with the monoclonal antibody to GFAP made visible by a fluorescein isothiocyanate-conjugated antibody.

within and outside tranplants. Electrode tracks were reconstructed with reference to small electrolytic lesions (Fig. 4*b*) and matched with transplantation sites made visible by pre-labelling the transplanted cells with fluorescent latex microspheres in two animals. Microscopic observation on sections stained with an antibody against glial fibrillary acidic protein (GFAP)[8], an astrocytic marker, revealed that transplanted astrocytes were localized only in the vicinity of the transplants (Fig. 4). The cells were located in a region displaying an increased immunoreactivity for GFAP (Fig. 4*b*), which reflected the reactive gliosis due to local damage by the injection. Reactive gliosis was found also in regions where non-astrocytic cells and pre-frozen cells had been injected. The OD shift to the non-deprived (ipsilateral) eye was only present in the cell population situated within the transplants (Fig. 4*a*). In a second control experiment, we implanted two additional cats with cultured fibroblasts instead of astrocytes. The OD histogram from the transplanted hemispheres does not differ significantly from those obtained from the control hemispheres, which had received previously frozen cell suspension (Fig. 2).

These data show that the transplantation of astrocytes cultured from the cortices of newborn kittens is sufficient to produce OD changes induced by light deprivation in adult cats. The finding that injection of previously frozen cell suspensions and of cultured fibroblasts does not lead to OD shifts indicates that the transplantation of cells *per se*, or reactive gliosis, which is always associated with brain damage, is not sufficient to induce OD plasticity in adult cats. Reactive gliosis is mediated only to a minor extent by glial proliferation[12,13], and hence may not lead to the generation of a sufficient number of immature astrocytes. In addition, it seems unlikely that macrophages are the relevant cell type in the transplanted cultured cells because (1) the cells constituted only a minor fraction of the cultures (<2%), and (2) a high density of macrophages has to be expected in all transplanted regions because of their massive proliferation and invasion after local cortical damage[14].

How do astrocytes support visual cortical plasticity, specifically axonal sprouting and synapse elimination? Several neurotrophic factors, such as nerve growth factor, basic fibroblast growth factor and the S-100 protein, are known to be synthesized and released by astrocytes[15,16]. The ability to release trophic factors is developmentally regulated[15]. It is conceivable that such factors are released by immature astrocytes, and are selectively taken up by active terminals to support axonal sprouting or neurite extension. Furthermore, synapse elimination could be mediated by active separation of synapses by glial processes, and subsequent phagocytosis of the terminals. Such a mechanism has been observed in the normal development of the spinal chord[17-19]. A similar involvement of astrocytic processes in the regulation of synapses is found in the hypothalamo-neurohypophyseal system[20-23]. Recently it was shown that the increase of synapse density which occurs in glia-free cerebellar cultures is only reversed when astrocytes are transplanted to the cultures[24]. The temporal limitation of synapse elimination to periods when immature astrocytes are present could be due to the loss of the astrocytes' ability during maturation to undergo morphological changes and to perform phagocytosis[25,26].

The data presented here further support the hypothesis that immature glial cells are causally involved in visual cortical plasticity. The mechanisms underlying the experience-dependent change of cortical connectivity discussed above could also explain the beneficial effect of transplanted astrocytes on behavioural recovery after cortical damage[27]. It remains to be shown, however, whether astrocytes actively participate in the plastic changes proper. ☐

Target size regulates calibre and myelination of sympathetic axons

James T. Voyvodic*

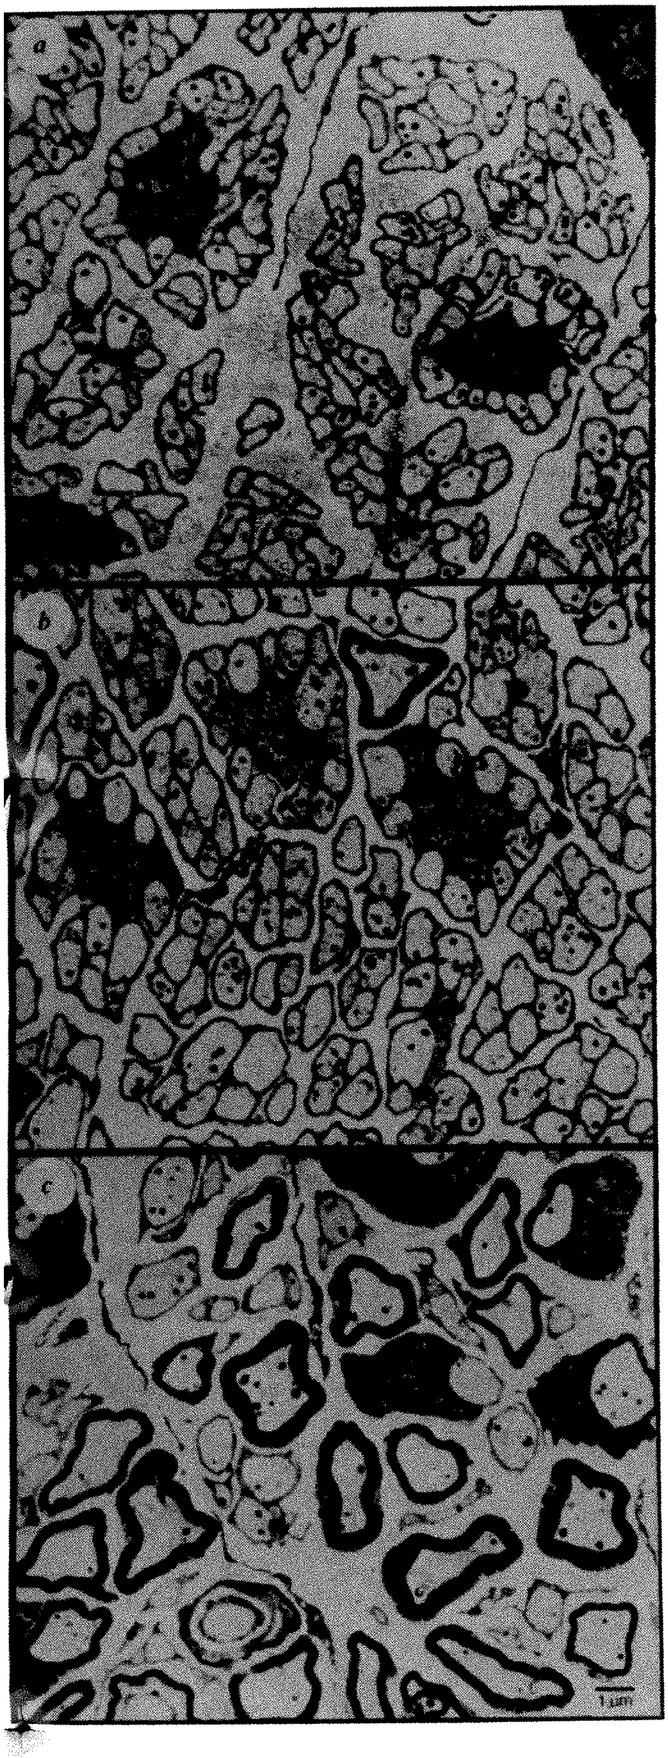
Department of Anatomy and Neurobiology,
Washington University Medical School, 660 S. Euclid, St Louis,
Missouri 63110, USA

AXONS in vertebrate peripheral nerves are ensheathed by Schwann cells. For some axons, this sheath consists of a single layer of glial cell cytoplasm and plasma membranes; for other axons, Schwann cells form multilayered myelin. Whether or not a Schwann cell makes myelin is determined by a signal from the axon[1,2], but the nature of this signal is not known. Here I show that sympathetic postganglionic axons, which are normally not myelinated, become myelinated when their calibre is increased as a result of increasing the size of the peripheral target they innervate. This result implies that axon calibre, which is known to be correlated with myelination[3], is in fact the crucial determinant of whether an axon becomes myelinated. Furthermore, the finding that increasing or decreasing target size causes corresponding increases or decreases in axon size indicates that axon calibre is itself regulated by retrograde signals from peripheral target tissues.

To study the effect of peripheral target size on ganglion cell axons, the relative size of a peripheral target of the superior cervical ganglion was altered during development by changing the ratio between the amount of target tissue and the number of innervating nerve cells in the ganglion. The target tissue tested in these experiments was the rat submandibular salivary gland. To make a smaller target than normal, the submandibular duct was ligated in 4-week-old rats; this results in glands weighing approximately 20% of normal when the animals reach 30 weeks of age[4-6]. These smaller glands were innervated by a normal number of superior cervical ganglion neurons (3,800 axons on average). In a second group of rats, relative target size was increased by cutting one branch of the sympathetic nerve innervating the gland at birth. When these animals were examined at 30 weeks of age, the partially denervated glands were of normal size, but were innervated by only 5-50% the normal number of sympathetic neurons[6].

---

* Present address: Department of Biology (Medawar Building), University College London, London WC1E 6BT, UK.



◀ FIG. 1 Effect of target size on the calibre of postganglionic sympathetic axons innervating the submandibular gland. Axons innervating: *a*, small target (submandibular duct ligated at 4 weeks of age); *b*, control target; *c*, large target (gland partially denervated at birth). All determinations were made in adult animals (30 weeks). Mean axon diameters were: *a*, 0.80 ± 0.01 μm; *b*, 1.15 ± 0.01 μm; *c*, 1.43 ± 0.02 μm. A portion of nerve midway between the gland and the external carotid nerve trunk was removed from 6-month-old animals after death; nerves were fixed by immersion and processed for electron microscopy as previously described[6]. Axon circumference was measured from electron micrographs (4,000×) using a digitizing tablet, and axon diameters were calculated as circumference/π. Scale bar is the same for all 3 panels.

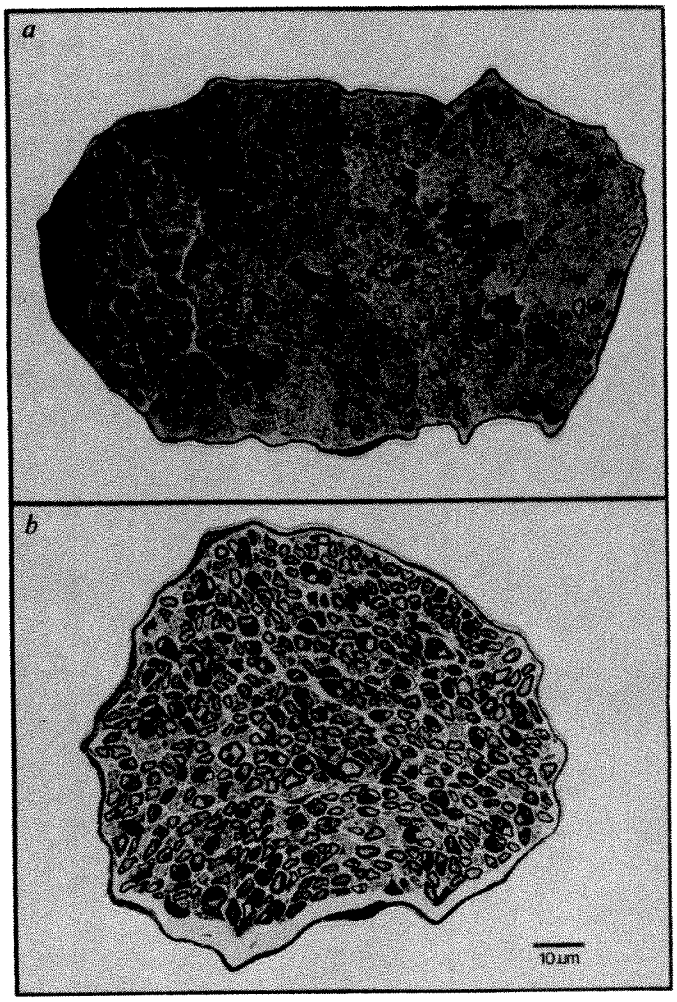


FIG. 2 Effect of increasing target size on the myelination of sympathetic axons. Electron microscope photomontages of whole postganglionic nerves innervating the submandibular gland in *a*, control (sham operated) nerve and *b*, nerve innervating relatively enlarged target (partially denervated at birth); both nerves are shown at the same magnification. In *a*, there are 3,192 unmyelinated and 25 myelinated axons; in *b*, 304 axons are unmyelinated and 386 are myelinated. Nerves were prepared for electron microscopy as described in the legend to Fig. 1. Retrograde labelling of the postganglionic nerve with horseradish peroxidase confirmed that at least 95% of the axons seen in cross-sections were axons of superior cervical ganglion neurons[6].

The postganglionic nerves carrying sympathetic axons to the submandibular gland were cut in cross-section and examined by electron microscopy (Fig. 1). Decreasing relative target size resulted in axons whose diameters were on average 31% (±0.5% s.e.m.) smaller than control axons, whereas increasing relative target size resulted in axons whose diameters were 24% (±1.7%) larger than normal. These changes in axon diameter are comparable to the magnitudes of changes previously observed in cell soma diameter and dendritic length when target size is altered under similar experimental conditions[6]. Taken together, these observations suggest that retrograde signals from the target provide a general mechanism for regulating the size of superior cervical ganglion neurons and their processes.

Target-induced changes in the size of the axon were associated with significant changes in the way in which these axons were

TABLE 1 Effect of axonal target size and preganglionic denervation on Schwann cells associated with postganglionic sympathetic axons

Experimental condition	Number of animals	Target size (μg/axon)	Total number of axons	Number of myelinated axons	Total number of Schwann cells/ cross-section
Small target	3	24 ± 4	3,596 ± 102	13 ± 1	323 ± 19
Control	4	90 ± 4	3,777 ± 90	24 ± 4	426 ± 39
Large target A	3	252 ± 56	1,620 ± 396	440 ± 189	1,111 ± 352
Large target B	2	532 ± 27	636 ± 38	291 ± 67	470 ± 75
Large target C	2	1,463 ± 155	233 ± 15	140 ± 1	233 ± 15
Preganglionic denervation					
Control target	2	73 ± 3	3,971 ± 458	19 ± 5	401 ± 22
Large target	2	954 ± 506	595 ± 292	141 ± 57	—

In the top part of the table, animals with relatively large targets were divided into 3 groups (A–C) because of the wide range of sizes produced by partial denervation (see text). Data in the lower part of the table show the effect of partial denervation of the submandibular gland for animals in which the preganglionic nerve was cut at birth[6]. The number of Schwann cells in a cross section of the nerve was estimated by dividing the total number of axons in the nerve by the number of axons per Schwann cell (calculated as described in Fig. 3.) Values are given ±s.e.m.

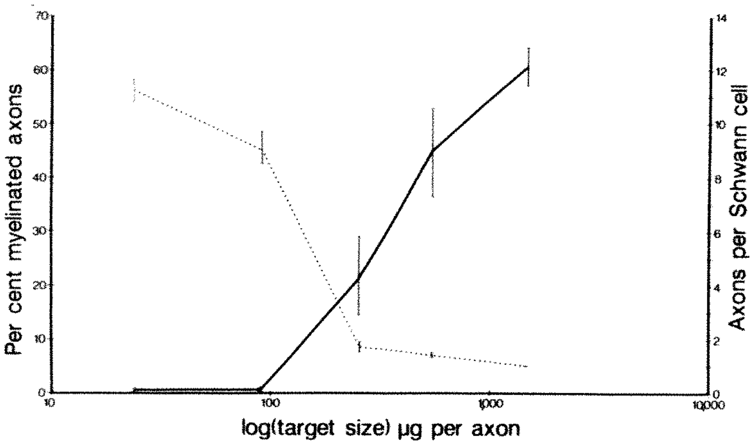

FIG. 3 Influence of target size on myelination, expressed as the percentage of axons that are myelinated (unbroken line), and on the number of axons ensheathed by each Schwann cell (dotted line). Target size is defined as the mass of the submandibular gland divided by the number of innervating sympathetic axons (counted in photomontages of whole nerves, as in Fig. 2). Each data point is the mean of values from several animals (Table 1). The number of axons ensheathed per Schwann cell was counted for each glial cell whose nucleus was visible in the plane of section; axon profiles in direct contact with the Schwann cell membrane were considered to be ensheathed by that glial cell.

ensheathed by Schwann cells. In control animals, 99.3% (±0.1% s.e.m.) of the axons in the postganglionic nerve were unmyelinated. When relative target size was increased by partial denervation, there was a dramatic increase in the number of myelinated axons in the nerve (Fig. 2). The absolute number of myelinated axons increased twelve times, on average, over the number in control nerves. Moreover, the fraction of axons that was myelinated increased progressively with increasing size of the peripheral target; for the largest targets, 60% of the axons were myelinated (Table 1; Fig. 3). When postganglionic nerves innervating experimentally enlarged targets were examined at multiple sites between the ganglion and the gland, the number of myelinated axons counted at each level was significantly above the number present in controls, indicating that these axons were myelinated along their entire length. Finally, an increase in myelination could be induced by increasing target size even if the superior cervical ganglion was denervated at birth (Table 1), suggesting that the increased myelination does not depend on electrical activity in the ganglion cells.

Two lines of evidence in this study indicate that the signal for Schwann cells to myelinate sympathetic axons is an increase in axon calibre. First, in agreement with previous reports[3,7,8], there was a clear size threshold above which axons became myelinated. Whereas 95% of unmyelinated axons were less than 1.6 μm in diameter, regardless of the experimental conditions, 90% of myelinated axons were greater than 1.6 μm in diameter. Second, even for axons below this size threshold for myelination, the number of axons ensheathed by each Schwann cell varied systematically with target size and axon calibre. Thus, when axon calibre was decreased by making a smaller target, there was no significant change in the number of myelinated axons in the postganglionic nerve, but there was a significant increase in the average number of axons ensheathed by each glial cell. On the other hand, as target size and axon calibre were increased in these experiments, the average number of axons associated with each glial cell gradually decreased (Fig. 3). This decrease was accompanied by an increase in the total number of Schwann cells present in the nerve (Table 1).

These systematic changes in the way in which Schwann cells ensheath axons of different sizes imply that Schwann cells are capable of responding to changes in axon calibre long before the axons reach the size threshold for myelination. Interestingly, the point at which Schwann cells switched from simple ensheathment to myelination was the point at which the ratio of axons to Schwann cells approached unity (Fig. 3). This relationship suggests that a Schwann cell that does not produce myelin might be triggered to begin myelination not because it detects some critical axon diameter, but rather because it reaches a point where it can no longer accommodate further axon growth by reducing the number of axons ensheathed. After Schwann cells switch to a myelinating phenotype, they once again respond to axon growth in a graded manner. In this case, however, the response is not to relinquish axons, but to add additional layers of compact myelin[7].

These results imply that there are no qualitative differences between axons that normally become myelinated and those that do not: increasing the size of a normally unmyelinated axon is sufficient to induce Schwann cells to myelinate it. These experiments also show that the calibre of peripheral axons is regulated by the size of their target. This regulation provides a mechanism by which the nervous system can continuously adjust to the growth of target tissues by modifying axonal conduction properties through retrograde signals from the target; these signals affect both axon size and myelination. □

Membrane depolarization evokes neurotransmitter release in the absence of calcium entry

B. Hochner, H. Parnas & I. Parnas

The Otto Loewi Center, Department of Neurobiology,
The Hebrew University, Jerusalem, Israel

THE discovery that Ca^{2+} is necessary for the release of neurotransmitter, the primary means by which nerve cells communicate, led to the calcium hypothesis of neutransmitter release[1–4], in which release is initiated after an action potential only by an increase in intracellular Ca^{2+} concentration near the release sites and is terminated (1–2 ms) by the rapid removal of Ca^{2+}. Since then, the calcium-voltage hypothesis has been proposed[5,6], in which the depolarization of the presynaptic terminals has two functions. First, in common with the calcium hypothesis, the Ca^{2+} conductance is increased, thereby permitting Ca^{2+} entry Second, a conformational change is induced in a membrane molecule that renders it sensitive to Ca^{2+}, and then binding of Ca^{2+} to this active form triggers release of neurotransmitter. When the membrane is repolarized, the molecule is inactivated and release is terminated, regardless of the local Ca^{2+} concentration at that moment. This hypothesis, in contrast to the calcium hypothesis, accounts for the insensitivity of the time course of release to experimental manipulations of intracellular Ca^{2+} concentation[7–11] Furthermore, it explains rapid termination of release after depolarization, even though Ca^{2+} concentration may still be high. Here we describe experiments that distinguish between these two hypotheses and find that our results support the calcium voltage hypothesis.

A critical test to distinguish the two hypotheses for the mechanism of neurotransmitter release separate the two effects of depolarization by raising intracellular Ca^{2+} and inducing membrane depolarization without entry of Ca^{2+} The calcium hypothesis would then predict that the membrane depolarization would not increase release, whereas the calcium-voltage hypothesis would predict an increase in release, locked in time to the depolarizing pulse The introduction of photosensitive Ca^{2+} chelators, the 'caged Ca^{2+}' compounds[12], makes such tests feasible These compounds have a high affinity for Ca^{2+}, but after exposure to light, the affinity is reduced and Ca^{2+} is released It is therefore possible to induce a phasic increase of Ca^{2+} concentration inside a presynaptic terminal without changing the membrane potential

Zucker and Haydon[13] used a caged Ca^{2+} compound, nitr-5, to test the calcium-voltage hypothesis, and found that asynchronous transmitter release was induced by photolysis of nitr-5 In the absence of Ca^{2+} entry, as depolarization did not affect this asynchronous release, it was concluded that membrane depolarization has no direct role in the release process The experiments underlying this conclusion, however, were made on a synapse in culture, where release is slow It is possible that, unlike in fast synapses, a change in membrane potential does not play a part in determining the time course of release, and/or that the experimental protocol was not designed to bring out such effects (see our delay histogram, Fig 3) We used nitr-5 to test the calcium-voltage hypothesis at a conventional fast synapse, the neuromuscular junction of the opener muscle in the first walking leg of the small crayfish *Procambarus clarkii* It has been indicated that in this preparation membrane potential has a role in addition to the classical one of opening Ca^{2+} channels[5,14]

Figure 1 depicts the time course of the effects of pressure-injecting nitr-5 into the excitatory axon through an intracellular microelectrode placed close to the terminal[15] Baseline responses to twin impulses (20 ms apart) recorded shortly after the intracellular penetration are shown in Fig 1*a* A reduction of release was apparent within three minutes after the start of injection (Fig 1*b*) As time elapsed and more nitr-5 was injected into the axon, release was further reduced (Fig 1*c*) until, after 18 min, it was nearly abolished (Fig 1*d*) This reduction in release is expected because nitr-5 chelates Ca^{2+} and its K_D in darkness is close to the resting level of intracellular Ca^{2+} ($\sim$0 1 μM) These results confirm that nitr-5 is reaching the nerve terminals At this state, the frequency of stimulation was raised to load the terminal with Ca^{2+} and to allow release to be measurable (Fig 2*a*) A flash of light was then delivered which resulted in a transient threefold elevation of the evoked release (Fig 2*b*) About one second after the flash, release is stabilized at a level higher than the control (compare Fig 2*a* with Fig 2*b*), indicating that the increase of intracellular Ca^{2+} concentration achieved by photolysis of nitr-5 is in a range that is effective for release

Given these results, nitr-5 could be directly used to test the unique feature of the calcium-voltage hypothesis To this end, we blocked Ca^{2+} entry using an extracellular solution essentially devoid of Ca^{2+} Addition of EGTA damages the preparation, so we added a high concentration of Mg^{2+} (12 5 mM) both to block any possible entry of Ca^{2+} and also to substitute for Ca^{2+} in opening postsynaptic glutamate channels[16] The effect of

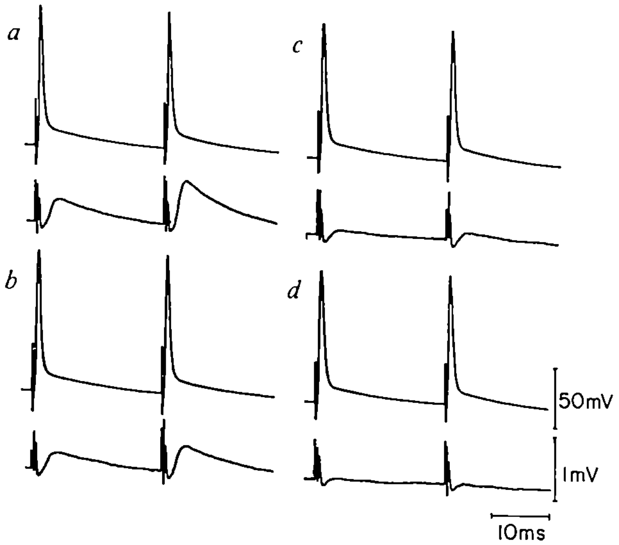

FIG 1 *a–d*, Pressure-injection of nitr-5 reduces synaptic release Upper traces show the axon action potential Lower traces show the synaptic potentials Twin impulses, 20 ms apart, were given at 3 3 Hz Each record is an average of 50 sweeps *a*, Control, before nitr-5 injection, and *b*, 3 min, *c*, 10 min and *d*, 18 min after beginning of injection of nitr-5 The excitatory axon was impaled distally to the main bifurcation[15] by an intracellular microelectrode, which served for recording and for pressure injection of nitr-5 The axon was stimulated by a suction electrode at its entry to the opener muscle Another intracellular electrode recorded synaptic potentials from a muscle fibre between these two sites

METHODS Crayfish were supplied by Atchafalaya, Louisiana The first walking legs of small (body length 4–4 5 cm) animals were used The bevelled microelectrode contained 50 mM nitr-5 (tetrasodium salt, Calbiochem), 35 mM $CaCl_2$, 85 mM KCl, 10 mM Tris-HCl, pH 7 4, and 0 5% fast green For pressure injection (1 s, 10–40 psi) the Pico-Injector Model PLI-100 (Medical System) was used Between 40–100 injection pulses were given during a period of ~30 min E p s ps were recorded with a microelectrode containing 2 5 M potassium acetate (6–10 MΩ) The preparation was perfused with a solution containing 220 mM NaCl, 5 4 mM KCl, 12 mM $CaCl_2$, 2 5 mM $MgCl_2$, 10 mM Tris-maleate, pH 7 6, at 18–20 °C Transilluminating light was filtered to remove wavelengths below 475 nm to avoid nitr-5 photolysis voltage on the probability of release was assessed by constructing synaptic delay histograms[3,5] After the injection of nitr-5 and perfusion with the Ca^{2+}-entry blocking solution, evoked release was abolished That is, miniature endplate potentials (m e p ps) were about equally distributed 10 ms before and 10 ms after stimulus pulses (Fig 3*b*) Then, while the nerve was being stimulated, three flashes of light (about 40 s apart) were given The results were pooled in a histogram (Fig 3*c*) Two changes occurred (compare Fig 3*b* and *c*) First, the baseline level of spontaneous m e p ps increased by more than 6 times Second, an additional increase in the rate of release was observed in the time range 2–4 ms after the stimulus That is, there was now evoked release Furthermore, the time range of this evoked release was consistent with the time course of release in the presence of extracellular Ca^{2+} (refs 5, 14) We obtained similar results in four further experiments

The increase in transmitter release after each flash was transient For example, delay histograms constructed from the first 200 impulses (10 s) following the first flash contained 7 m e p ps (in 10 ms following the stimulus), whereas the next 200 impulses resulted in only 2 m e p ps The transient increase in release indicates that after each flash the intracellular Ca^{2+} concentration increased briefly and that the Ca^{2+} was then removed by the intracellular Ca^{2+}-buffering systems The observed evoked release could have been due to a temporary elevation of intracellular Ca^{2+} concentration Alternatively, it could have resulted from a reduced ability of the photolysed nitr-5 to chelate small amounts of Ca^{2+} that might have entered the terminal As the reduction in the affinity of the photolysed nitr-5 is not reversible but the increased release was transient we favour the first possibility

The level of stimulus-evoked release in our experiments was rather lower than that seen in the presence of extracellular Ca^{2+} It is possible that intracellular Ca^{2+} buffers compete with the nitr-5 to strip away some of its Ca^{2+}, diminishing the increase in Ca^{2+} after a flash We therefore examined the effect of interfering with intracellular Ca^{2+}-buffering mechanisms using the uncoupler carbonyl cyanide *m*-chlorophenylhydrazone (CCCP)[17] Two additional modifications were made in this experiment First, 0 2 mM Ca^{2+} was added to the bathing medium to improve the ability of the axon to sustain action potentials Second, as there was a small amount of Ca^{2+} in the medium, the measures for blocking Ca^{2+} entry were strengthened by including 2 mM Mn^{2+} in addition to the 12 5 mM Mg^{2+} In the controls without nitr-5 injection, release could not be evoked at stimulation rates of 10 Hz In 1,000 pulses, only six quanta were seen This was so even in control trials where 3,4-diaminopyridine (0 1 mM) was added and the nerve action potential was clearly broadened Figure 4*a* (traces 1 and 2, fast and slow time base, respectively) shows synaptic responses in the presence of extracellular Ca^{2+} 75 minutes after injection of nitr-5 Figure 4*b* shows the block of release in the Ca^{2+}-blocking medium The responses seen in Fig 4*c* were obtained 11 minutes after application of 10 μM CCCP Two effects are evident First, there was increase in the spontaneous release (Fig 4*c*, trace 2), presumably resulting from an increase in intracellular Ca^{2+} concentration The more striking result, however, was the appearance of synaptic potentials These are seen even after single impulses without averaging Now after a flash of light (Fig 4*d*), the amplitude of evoked excitatory postsynaptic potentials (e p s ps) and the frequency of spontaneous m e p ps increased even more

Interestingly, Zucker and Lando[17], who applied 10 μM CCCP in the same preparation, did not observe evoked release The difference between their results and ours may be explained by

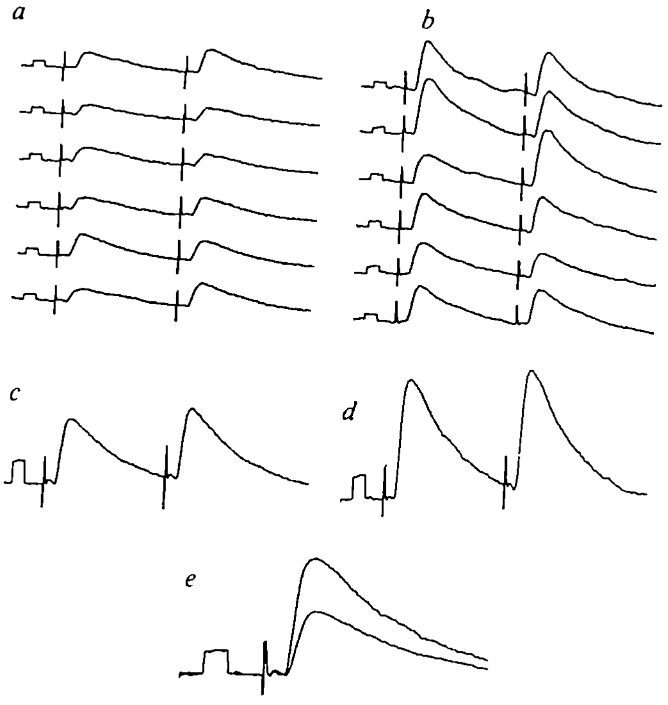

FIG 2 Photolysis of nitr-5 caused an increase in evoked release This is a continuation of the experiment shown in Fig 1 Twin-impulse stimulation (20 ms intervals) at 10 Hz slowly restored release (compare with Fig 1*d*) *a*, Single responses (sampled at 5 Hz) after e p s ps reached a steady-state level *b*, Single responses after a flash of light (top to bottom) *c*, An average of 10 sweeps before the light flash *d*, An average of 5 sweeps after the light flash *e*, Superposition of the first responses in *c* and *d* Calibration pulse 1 mV, 2 ms

METHODS The xenon lamp was an ensemble of a Strobex Power Pack, model 238 and a Strobex Lamp model 278 (Chadwick-Helmuth, California) The flash lamp was mounted in one of two configurations In the first, the lamp was aimed with an angle of 45°, in the second it was positioned vertically over the preparation The light was filtered to remove short-wave ultraviolet (<305 nm) The energy of the flash was about 180 joules for the first configuration and 100 joules for the second A light flash without injection of nitr-5 had no effect The light was focused with an elliptical mirror (Pichel, California) to give an image of ~7 mm at the focal plane

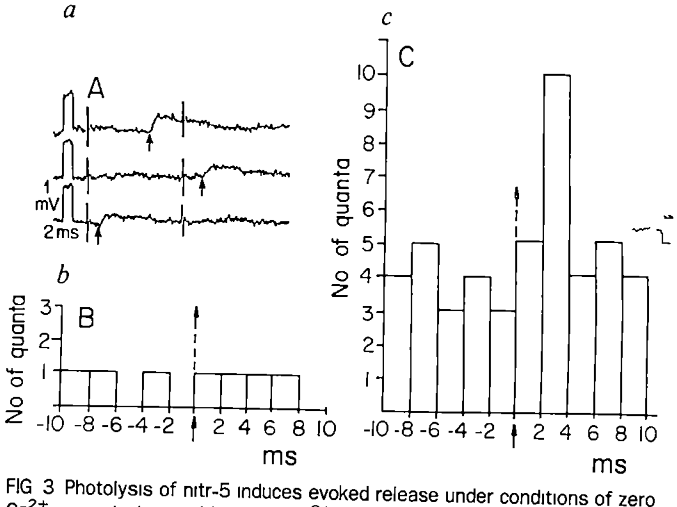

FIG 3 Photolysis of nitr-5 induces evoked release under conditions of zero Ca^{2+} concentration and 12 5 mM Mg^{2+} in the external medium Twin impulses (20 ms apart) were given at a repetition rate of 10 Hz The delay from the stimulus to a quantum response was measured (arrows in *a*) Delay histograms (bin size 2 ms) describing the probability of occurrence of single events are given for 10 ms before the stimulus (negative timescale) and after the stimulus Responses were measured for a period of 10 ms after the two impulses in a sweep and lumped together For responses appearing before stimulation, measurements were taken for two successive periods of 10 ms before the first stimulus and lumped together *a*, Examples of records after a flash of light *b*, Delay histogram after injection of nitr-5 in the dark *c*, Delay histogram in a nitr-5 loaded preparation following 3 consecutive flashes of light For each histogram, 600 sweeps were taken, the histogram contains responses to 1,200 impulses Arrows in *b* and *c*, indicate point of stimulation

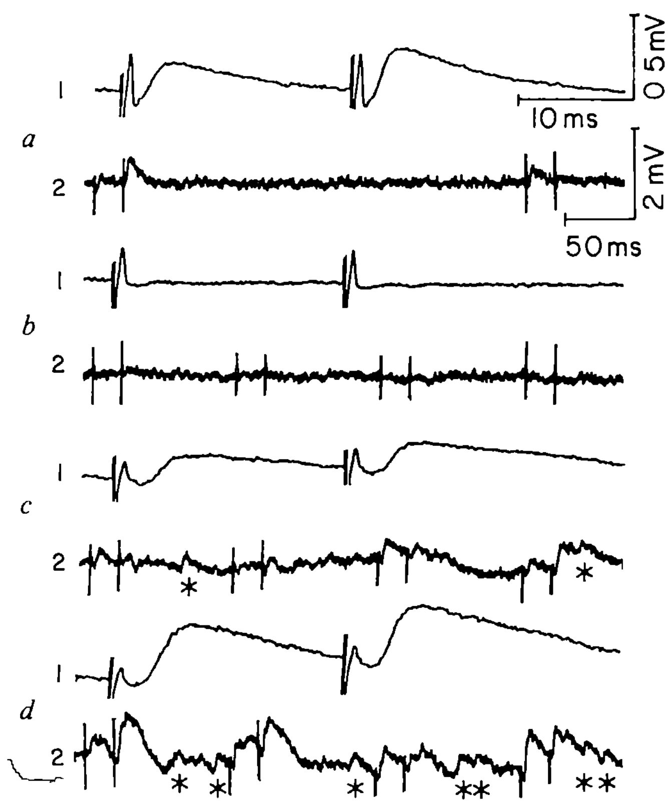

FIG 4 Ca^{2+} loading of the nerve terminal supports action potential evoked release in the absence of Ca^{2+} entry *a*, Trace 1 is an average of 100 traces taken at 3 3 Hz 75 min after the injection of nitr-5, trace 2 is a single trace, at a slow time base, showing evoked release but not spontaneous release *b*, Records taken 4 min after wash with a solution containing 0 2 mM Ca^{2+}, 12 5 mM Mg^{2+} and 2 mM Mn^{2+} The wash was very rapid and effective as the washing solution was directly aimed at the small space of the opener muscle in the shell It is shown in trace 1 that evoked release is completely blocked, even at 10 Hz simulation rate and in trace 2 that no m e p ps are seen Eleven minutes after addition of 10 μM CCCP, evoked release can be seen in the average record in *c* (trace 1) and m e p ps (asterisks) in trace 2 The single trace (2) in *c* also shows evoked e p s ps *d*, After a flash of light, a further increase in the size of the evoked response is evident in trace 1 (average of 50 traces), with a concomitant increase in m e p ps frequency in trace 2 In the averaged responses in *a*(1)–*d*(1), the nerve action potential appearing before the synaptic potential originates from cross talk between the two microelectrodes

two factors (1) their measurements were taken too long after the application of CCCP, and (2) the injection of nitr-5 might have postponed the build-up of a toxic level of Ca^{2+} concentration because of its Ca^{2+}-chelating properties It is known that at a high intracellular Ca^{2+} concentration, evoked release is blocked while spontaneous release continues[18] Indeed, we measured release shortly after application of CCCP, when the frequency of spontaneous m e p ps was still low

We conclude that (1) after a flash of light in nitr-5-injected axons, particularly in the presence of CCCP, spontaneous release is enhanced, these m e p ps appearing randomly in time, (2) under conditions of raised intracellular Ca^{2+}, depolarizing impulses evoked synchronous release, despite the blocking of Ca^{2+} entry, and (3) the time course of this evoked release was normal Therefore, in the fast synapse of the crayfish neuromuscular junction, membrane depolarization plays a part in the release process, in addition to its well-known effect of opening Ca^{2+} channels ☐

Germ-line transmission of a disrupted β_2-microglobulin gene produced by homologous recombination in embryonic stem cells

Maarten Zijlstra*, En Li*, Fereydoun Sajjadi†, Suresh Subramani† & Rudolf Jaenisch*

* Whitehead Institute for Biomedical Research, Nine Cambridge Center, and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02142, USA
† Department of Biology, University of California, B-022 Bonner Hall, San Diego, La Jolla, California 92093, USA

MAJOR histocompatibility complex (MHC) class I molecules are integral membrane proteins present on virtually all vertebrate cells and consist of a heterodimer between the highly polymorphic α-chain and the β_2-microglobulin (*β2-m*) protein of relative molecular mass 12,000 (ref 1) These cell-surface molecules play a pivotal part in the recognition of antigens, the cytotoxic response of T cells, and the induction of self tolerance[1,2] It is possible, however, that the function of MHC class I molecules is not restricted to the immune system, but extends to a wide variety of biological reactions including cell–cell interactions For example, MHC class I molecules seem to be associated with various cell-surface proteins, including the receptors for insulin, epidermal growth factor, luteinizing hormone and the β-adrenergic receptor[3–6]. In mice, class I molecules are secreted in the urine and act as highly specific olfactory cues which influence mating preference[7,8]. The *β2-m* protein has also been identified as the smaller

ES cells were electroporated with the targeting vector and selected for G418^r as described in Fig 2

* Expressed per total number tested

† Average number per 48-well plate

‡ The frequency of targeting was calculated using the Poisson distribution formula, in which the fraction of plates with no recombinants, *P*(0) is given by e^{-m}, where *m* is the average number of recombinants per pool ($m = -\ln P(0)$) The targeting efficiency is the ratio of *m* to the average number of independent G418^r clones per pool, which is half the observed number based on the assumption that each pool has on average two sibling clones PCR$^+$, scored positive by PCR

component of the Fc receptor in neonatal intestinal cells[9], and it has been suggested that the protein induces collagenase in fibroblasts[10]. Cells lacking *β2-m* are deficient in the expression of MHC class I molecules, indicating that the association with *β2-m* is crucial for the transport of MHC class I molecules to the cell surface[1]. The most direct means of unravelling the many biological functions of *β2-m* is to create a mutant mouse with a defective *β2-m* gene We have now used the technique of homologous recombination to disrupt the *β2-m* gene. We report here that introduction of a targeting vector into embryonic stem cells resulted in *β2-m* gene disruption with high frequency. Chimaeric mice derived from blastocysts injected with mutant embryonic stem cell clones transmit the mutant allele to their offspring

Pluripotent embryonic stem cells can be genetically manipulated in culture, and when introduced into a host blastocyst, contribute to all tissues of the chimaeric mouse[11,12] The contribution of an embryonic stem (ES) cell carrying a defined mutation to the germ line of the chimaera thus results in a new mouse strain carrying the mutation Gene targeting, mediated by recombination between a vector and homologous chromosomal sequences, has been used in ES cells to disrupt several genes, including the hypoxanthine-guanine phosphoribosyl transferase gene (*HPRT*)[13-15], the *int-2* proto-oncogene[14], the mouse *engrailed*-like gene *En-2* (ref 16) and the *adipson*, the aP2 and the *fos* gene[25] In these cases, the targeting vector contained the bacterial neomycin-resistance gene (*neo*^{r}) as a selectable marker gene facilitating the isolation of targeted clones More recently, the herpes simplex virus (HSV) thymidine kinase gene (*tk*) has been included in the vector to permit negative selection agains nonhomologous integration events[14] An alternative strateg using microinjection of a mutated gene fragment has been use to disrupt the *Hox1 1* gene in ES cells[17] Recently, germ-lir transmission of an *HPRT* mutant gene corrected by gene targeting has been reported[18], confirming that gene disruption in E cells can represent a general approach to generate defined mutations in mice

To mutate the *β2-m* gene, a replacement-type vector wa designed which combined several previously used characteristics[13,14] facilitating the detection of targeting events The vecto contained 10 kilobases (kb) of homology to the *β2-m* gene, *neo*^{r} cassette in the second exon lacking a polyadenylation sit and a *tk* gene at the 5′ end (Fig 1*a*) Initial Southern-blo analyses revealed, however, that 50% of randomly picked G418 resistant (Neo^r) ES cell clones had lost the *tk* gene Therefore no counter selection against non-homologous integration event was applied in our experiments

The following screening procedure was devised to allow rapid identification of targeted clones (Fig 2) D3 ES cells[12] were electroporated on day 0, divided into ~30 independent pools and grown for 3 5 days in normal medium, by which time a cell containing a targeting event had divided into ~8 daughter cells At that time, the pools of cells were split in half and subjected to drug selection One-half of each pool (each containing 15-40 G418^r colonies after plating) was grown for 10 days as a bulk culture and used for polymerase-chain-reaction (PCR) analysis to identify the presence of a targeted cell The other half of each

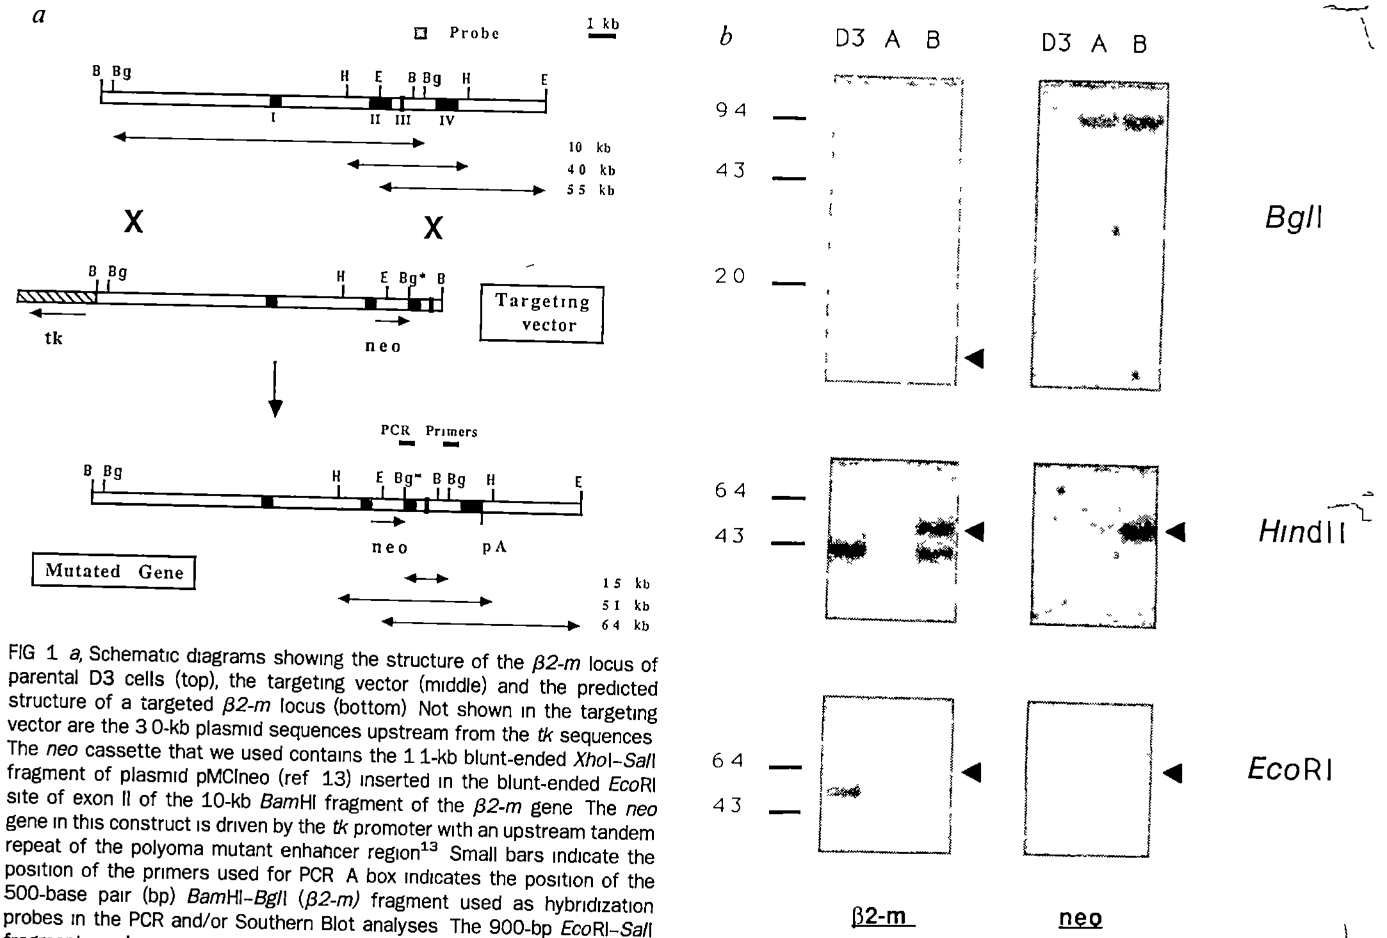

FIG 1 *a*, Schematic diagrams showing the structure of the *β2-m* locus of parental D3 cells (top), the targeting vector (middle) and the predicted structure of a targeted *β2-m* locus (bottom) Not shown in the targeting vector are the 3 0-kb plasmid sequences upstream from the *tk* sequences The *neo* cassette that we used contains the 1 1-kb blunt-ended *Xho*I-*Sal*I fragment of plasmid pMClneo (ref 13) inserted in the blunt-ended *Eco*RI site of exon II of the 10-kb *Bam*HI fragment of the *β2-m* gene The *neo* gene in this construct is driven by the *tk* promoter with an upstream tandem repeat of the polyoma mutant enhancer region[13] Small bars indicate the position of the primers used for PCR A box indicates the position of the 500-base pair (bp) *Bam*HI-*Bgl*I (*β2-m)* fragment used as hybridization probes in the PCR and/or Southern Blot analyses The 900-bp *Eco*RI-*Sal*I fragment used as a *neo* probe was derived from plasmid pMClneo (ref 13) Roman numerals denote the exons of the *β2-m* gene Arrows indicate the sizes of *Bgl*I, *Hin*dIII and *Eco*RI fragments hybridizing with the *β2-m* probe in DNA of parental D3 cells (top) and the predicted sizes in a targeted *β2-m* gene (bottom) Bg* is a *Bgl*I polymorphism present in exon II of the targeting vector (C57BL/6 DNA-derived, *β2-m*^{b} allele), but absent in the ES cell DNA (129J mouse-derived, *β2-m*^{a} allele) B, *Bam*HI site, Bg, *Bgl*I site, E, *Eco*RI site, H, *Hin*dIII site *b*, Southern-blot analyses of the structure of the *β2-m* locus in the DNA of parental D3 cells and two targeted clones A and B Hybridization probes as in *a* Triangles indicate diagnostic restriction enzyme fragments obtained after *Bgl*I, *Hin*dIII and *Eco*RI digestion Bars indicate migration of *Hin*dIII-digested λ DNA markers DNA (10 μg) was digested with the indicated enzymes, run on a 0 7% agarose gel, and blot-hybridized by standard procedures

* ES cells (10–20) were injected into C57BL/6J blastocysts and transferred to uteri of pseudopregnant recipients

† Assessed by the contribution of the agouti coat colour contributed by D3 cells (129J, agouti) on the black background of C57BL/6J mice

‡ Assessed by the presence of the dominant agouti coat colour in offspring after breeding with C57BL/6J females

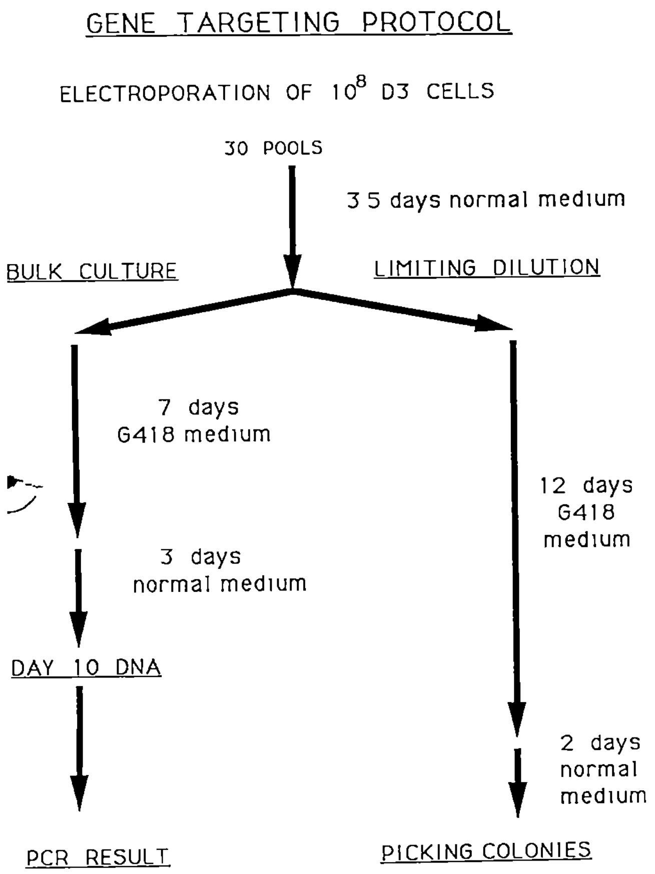

FIG 2 Electroporation of ES cells D3 ES cells[12] were routinely grown on γ-irradiated (2,000 rad) primary embryonic fibroblasts (EF) in DMEM medium supplemented with 15% FCS, 1×non-essential amino acids (Gibco) and 10^{-4} M β-mercaptoethanol Electroporation of 1×10^8 D3 cells using a BTX 300 transfector (50 μF, 275 V) with 25 μg ml^{-1} linearized vector DNA was performed as previously described[13] The electroporation conditions result in an 80% plating efficiency in comparison with non-electroporated D3 cells Electroporated cells were divided into 30 independent pools and seeded into individual 25-cm^2 tissue culture flasks on a feeder layer of EF Selection procedure After three one-half-day's growth in normal medium, cells of individual pools were trypsinized and divided into two halves One half was seeded into a 48-well plate on irradiated EF derived from transgenic mice expressing a *tk-neo* construct[12] and selected for 12 days in medium containing 150 μg ml^{-1} (active substance) G418 From day 6–14, the medium was supplemented with 15% D3 cell-conditioned medium (0 22-μm filtered) and 1,000 U ml^{-1} recombinant mouse leukaemia inhibitory factor (LIF)[24] The other half was seeded as a bulk culture in a 25-cm^2 flask on the irradiated *neo*-expressing EF The bulk cultures were selected for 7 days in medium containing 150 μg ml^{-1} G418 and subsequently for 3 days in normal medium Thereafter, DNA derived from the bulk cultures were tested by PCR for the presence of gene-targeted clones Subsequently, the sibling cultures in the 48-well dishes were used to isolate clones from those pools scored positive by PCR Clones were expanded and screened by PCR Thereafter, DNA of PCR^+ clones was characterized by Southern-blot analyses as outlined in Fig 1 For PCR, DNA from bulk cultures or individual clones was isolated, treated with proteinase K, deproteinized with phenol–chloroform, precipitated and washed with ethanol and dissolved in 10 mM Tris buffer pH 8 0, 1 mM EDTA by standard procedures DNA (250 ng) was tested by PCR under conditions recommended by the supplier (Perkin Elmer Cetus) with the addition of 2 mM $MgCl_2$, in 50 μl containing 200 pmol of each primer (*neo*, ATATTGCTGAAGAGCTTGGCGGCGAATGGG, *β2-m*, AAGGGAGGGAGAGAAGGAGAAGGTTAGCC) PCR was run for 40 cycles using a thermal cycler (Perkin Elmer Cetus) Denaturation was performed for 1 5 min at 94 °C, annealing for 2 min at 63 °C and extension for 4 min at 72 °C A 25-μl reaction sample was run on an 0 8% agarose gel and blot-hybridized by standard procedures

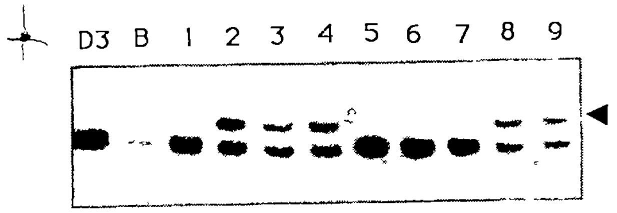

FIG 3 Germ-line transmission of mutant *b2-m* gene Southern blot of DNA from offspring of chimaeric males B2 and B3 (Table 2) The DNA was digested with *Eco*RI and probed with a *β2-m* probe as described in Fig 1 The arrowhead marks the fragment from the mutant *β2-m* gene (6 4 kb, see Fig 1) D3, parental ES line, clone B, mutant clone injected into blastocysts, numbers refer to individual offspring

pool was seeded into 48-well plates and propagated for 12 days in the presence of G418. As soon as pools containing targeted cells were identified by PCR analysis of the bulk cultures, clones were isolated from the corresponding sibling 48-well cultures, expanded and screened by PCR. The successful identification of targeted clones by this screening protocol depends critically on the plating efficiency of the trypsinized cells at day 3.5 after the initial electroporation. The use of a low trypsin concentration (0.025%)[19] and the seeding of the cells at high density ($2\text{–}4\times10^5$ cells cm^{-2}) resulted in a plating efficiency of >50%, thereby permitting partition of daughters of a single initially targeted cell into both sibling pools.

The results of two independent experiments are summarized in Table 1. In the first experiment, 7/32 cell pools, and in the second experiment, 19/28 cell pools, were identified to contain targeted cells by PCR. A large fraction of clones present in each of a total of seven positive pools were isolated, and targeted clones were identified by the PCR reaction in each pool. To confirm that the *β2-m* gene in the targeted clones was disrupted, DNA from seven independent clones was characterized by Southern-blot analysis using probes specific for the *β2-m* and neo^r genes (Fig. 1*b*). DNA of six clones showed the additional diagnostic *Bgl*I, *Eco*RI and *Hin*dIII fragments predicted from disruption of the *β2-m* gene by the targeting vector (Fig. 1*a*). DNA of one clone contained the diagnostic *Eco*RI and *Hin*dIII fragments, but lacked the *Bgl*I site in exon II (data not shown), most probably caused by a small mutation or deletion which can occur during a homologous recombination event[15].

The targeting frequency in our experiments was ~1 in 2.5×10^6 electroporated input cells or 1/25 of the G418^r clones. This is one to three orders of magnitude higher than the targeting frequencies reported for other genes[13-16,25]. There are at least two factors that could contribute to the high efficiency of *β2-m*-gene targeting. The gene could contain a hotspot of recombination, as suggested by the clustering of rearrangements in the first intron in the DNA of independent *β2-m* gene variants in lymphoma cell lines[20]. In addition, the lack of a polyadenylation site in the vector reduced the number of drug-resistant clones from non-homologous integration events by about fourfold (data not shown).

Northern-blot analysis indicated the presence of little, if any, *β2-m*-specific messenger RNA in undifferentiated D3 cells (data not shown). Therefore, high-frequency homologous recombination in ES cells is clearly not dependent on a high steady-state mRNA level as exemplified in the study described here for the *β2-m* gene, and observed previously for other genes[16,25]. In our view, the chromatin structure could be more important. It has been shown, for example, that the *β2-m* gene in F9 cells, which express only trace amounts of *β2-m* mRNA, is much more susceptible to digestion by DNAase I than it is in differentiated F9 cells, which express moderate levels of *β2-m* mRNA[21]. This suggests that the gene, even if it is expressed a little or not at all is in an 'opened' chromatin conformation.

To derive animals carrying a disrupted *β2-m* gene, two different targeted clones were injected into C57BL/6J host blastocysts. Whereas clone A resulted in a few animals with a low degree of chimaerism, extensive and healthy chimaeras were derived from clone B (Table 2). Chimaeric males were bred with C57BL/6J females. So far, three males have transmitted the ES cell genome to all of their offspring and three other males have transmitted it to part of their offspring (Table 2). A 100% transmission is expected for 'pseudomales', which are derived from a female host blastocyst injected with the male ES cell line[22]. In such animals, the XX germ cells of the female host are not capable of forming functional spermatozoa. So far, Southern-blot analysis was performed with tail DNA of 17 offspring from pseudomales B2 and B3 (Table 2), and revealed the presence of the additional *Eco*RI fragment predicted by inheritance of the disrupted *β2-m* gene in eight animals (Fig. 3). Our results, therefore, indicate that the disrupted *β2-m* gene is genetically transmitted according to mendelian expectations.

The animals heterozygous for the *β2-m*-gene disruption have so far not shown any detectable phenotype and will be intercrossed to obtain animals homozygous for the mutation. We expect that homozygous animals will lack MHC class I molecules on their cell surface and, as a consequence, be severely immunocompromised. Considering the various other functions the *β2-m* protein could have, failure to express the gene may lead to disturbance of embryonic development. The *β2-m* gene is expressed as soon as the two-cell stage[23], and thus is one of the earliest genes to be activated during mammalian development that is known. The phenotype of homozygous mutant mice should therefore help in understanding the various functions that the *β2-m* protein, as well as its ligands, has in the life cycle of mammals. □

Developmental regulation of stage-specific ribosome populations in *Plasmodium*

A. P. Waters, Chiang Syin* & T. F. McCutchan†

Malaria Section, Laboratory of Parasitic Diseases,
National Institute of Allergy and Infectious Disease, Building 4,
National Institutes of Health, Bethesda, Maryland 20892, USA

THE *Plasmodium* parasites are so far unique in biology in possessing developmentally regulated ribosomal RNA gene units[1]. Two different genes encode their small subunit rRNAs: one gene (*A*) yields transcripts predominant in the asexual blood-stage parasites, and the other (*C*) is mainly transcribed in the sporozoite forms that develop in the mosquito[1,2]. Developmental control of events allowing a switch in the complement of ribosomes must coordinate the production of the new class with selective inactivation and removal of the old. We show here that in *P. falciparum* the switch from *A* to *C* gene expression involves the control of

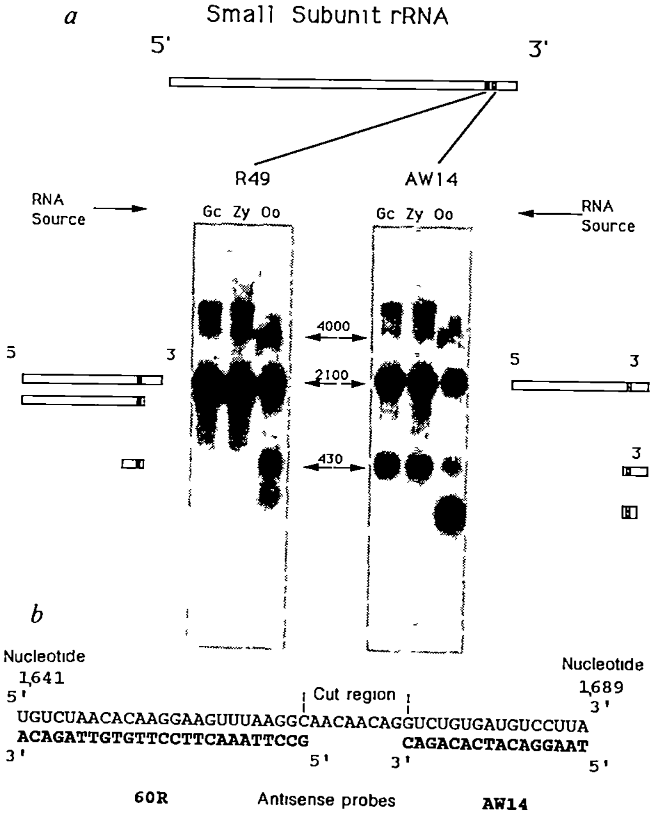

FIG 3 *a*, The *A*-gene small-subunit rRNA transcript is selectively cleaved during sexual development The probes were complementary to the regions indicated AW14 has the sequence 5'-TAAGGACATCACAGAC-3' and is complementary to nucleotides 1,674–1,689, probe 49R has been described[9] and is complementary to nucleotides 1,606–1,634, probe 60R has the sequence 5'-GCCTTAAACTTCCTTGTGTTAGACA-3' and was used to map the precise location of the initial cut Methods are described in the legend to Fig 2 *b*, Site of the initial cut in the *P falciparum A* gene The sequence of the *A*-gene small-subunit rRNA region between nucleotides 1,641–1,689 is given at the top The two antisense oligonucleotide probes, AW14 and 60R, are shown in bold at the appropriate locations The two probes hybridize at stringency to the two different processed RNA fragments in gametes and gametocytes The region of the first cut site is thus located to a region of no more than 10 nucleotides between the two probes

The structure of the stable precursor in gametocytes from the ribosomal *C* gene is also significant to the understanding of the transition process Oligonucleotide mapping has demonstrated that the entire 1,800 extra nucleotides in the precursor lies 5' to the mature transcript (data not shown) Such a precursor structure is like that of small-subunit rRNA precursor molecules found in yeast mutants that lack the gene for a ubiquinated ribosomal protein[6] It is possibile that a stage- (and binding sequence-) specific ubiquinated ribosomal protein is produced to aid the maturation of each type of rRNA transcript, this is under investigation at present

Although much is known about the generation of mature rRNA transcripts from the single multigenic precursor molecule, our results demonstrate that it can be a regulated, developmentally controlled process This control is minimally exerted at three levels, transcription, RNA processing and RNA degradation, facilitating the novel phenomenon of ribosome biogenesis, switching and turnover in *Plasmodium* Specific factors involved in these events during the hepatic stage of the *Plasmodium* life cycle could prove to be targets for novel drugs directed against malaria parasites and other micro-organisms These events can be easily assayed *in vitro* to test such drugs It is possible that other organisms with a defined dimorphic lifestyle could also display this type of control ☐

HEPATOCYTE growth factor (HGF) is the most potent mitogen for mature parenchymal hepatocytes in primary culture, and seems to be a hepatotrophic factor that acts as a trigger for liver regeneration after partial hepatectomy and liver injury. The partial purification and characterization of HGF have been reported[1–4]. We have demonstrated that pure HGF from rat platelets is a new growth factor[5,6] effective at concentrations as low as 1 ng ml^{-1}.

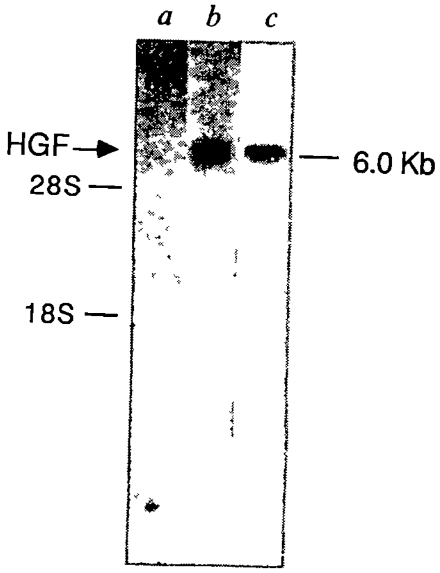

FIG 1 Northern hybridization of mRNAs from rat and human livers Poly(A)$^+$ RNAs were isolated from livers of normal adult rat (lane *a*) and CCl$_4$-treated rat (lane *b*) Lane *c* is human liver poly(A)$^+$ RNA (Clontech) The positions of the 28S and 18S ribosomal RNA markers are shown on the left Blots were hybridized with rat HGF cDNA (clone RBC1 1 4 kb insert)
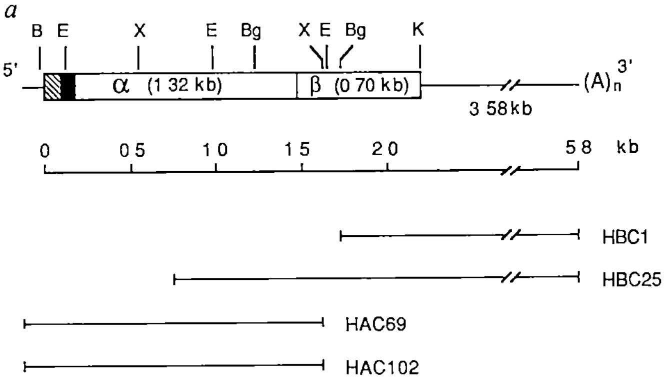
METHODS Poly(A)$^+$ RNAs (1 μg per lane) were electrophoresed into a 1% agarose gel containing 0 66 M formaldehyde[17] and blotted onto a nylon membrane filter (Genescreen plus, NEN) The filter was hybridized in 5× SSPE (800 mM NaCl, 50 mM sodium phosphate, 5 mM EDTA, pH 7 8), 5× Denhardt's solution, 10% dextran sulphate, 40% formamide, 0 1% SDS, 1 mM sodium pyrophosphate, 0 1 mg ml^{-1} sonicated *E coli* DNA at 40 °C overnight with a ^{32}P-labelled probe prepared from the 1 4 kb *Eco*RI fragment of the cDNA clone RBC1 (Amersham multiprime DNA labelling system) The filter was washed with 1 ×SSC containing 0 1% SDS at 60 °C, dried and then exposed on X-ray film for 2 days at −80 °C using an intensifying screen

he effects of HGF and epidermal growth factor (EGF) are dditive. The activity of HGF is not species-specific, although it loes not stimulate growth in Swiss 3T3 fibroblasts[5]. HGF has a elative molecular mass (M_r) of 82,000 and is a heterodimer omposed of a large α-subunit of M_r 69,000 and a small β-subunit f M_r 34,000 (ref. 6). Here we report the amino-acid sequence of uman HGF determined by complementary DNA cloning and the xpression of biologically active human HGF from COS-1 cells ransfected with cloned cDNA. The nucleotide sequence of the uman HGF cDNA reveals that both α- and β-chains are conained in a single open reading frame coding for a pre-pro precursor rotein of 728 amino acids.

HGF was purified to homogeneity from the platelets of 3,000 ats by a four-step procedure[5,6]. The yield was about 60 μg,



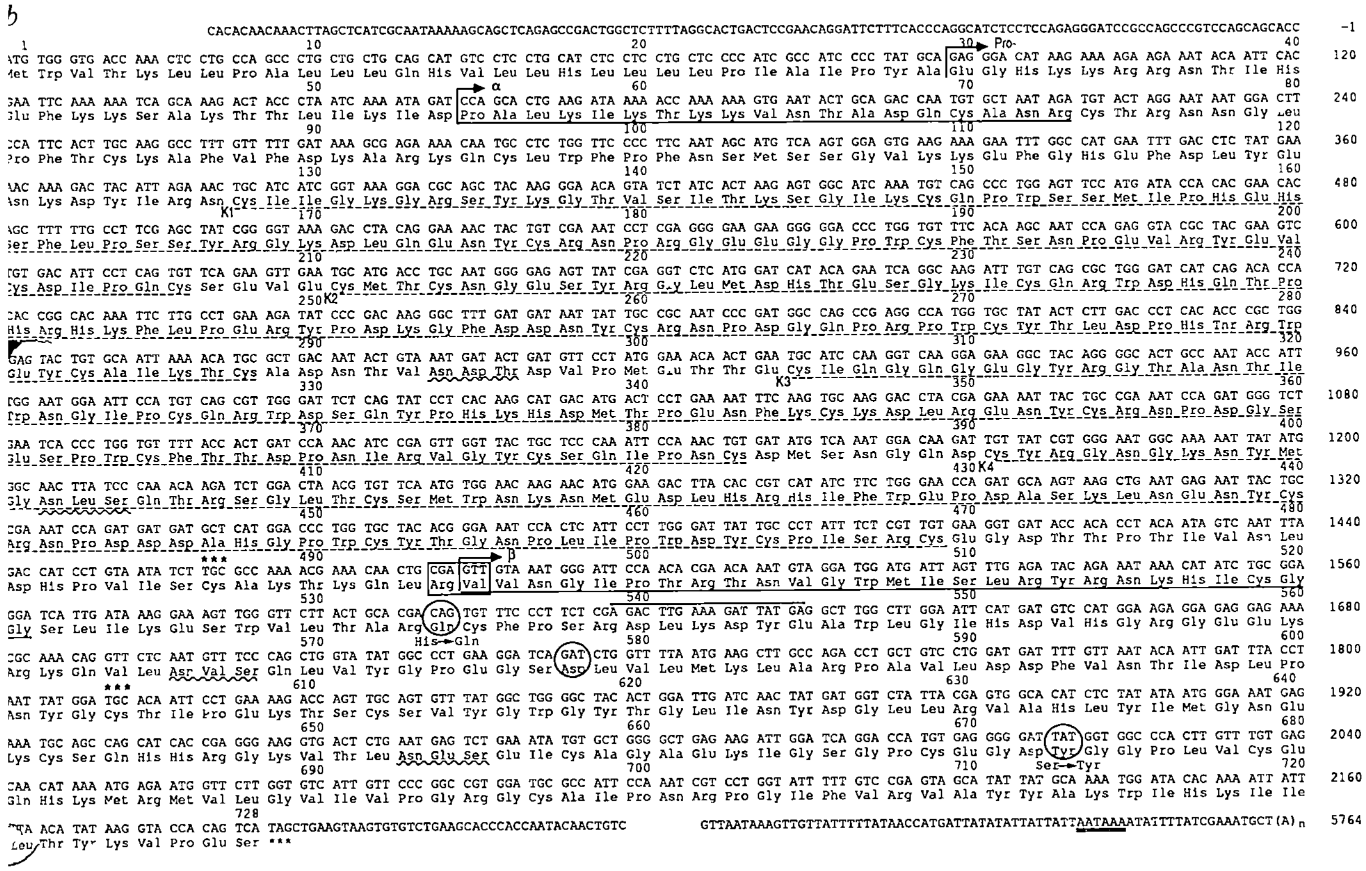


FIG. 2 The restriction map, nucleotide sequence and deduced amino-acid sequence of human HGF cDNA. *a*, Untranslated sequences are represented by a line and coding sequences are boxed. The open portion indicates the coding regions for the α- and β-chains. Hatched and black areas show the coding region for the signal peptide and pro-sequences, respectively. The scale is in nucleotides from the initiation codon ATG. *b*, The nucleotide numbers are given on the right, and amino acid numbers are given throughout. Experimentally determined N-terminal sequences of HGF α- and β-chains are underlined. The proteolytic cleavage site is boxed. An interchain S–S bridge is indicated by asterisks. Dotted underlines indicate the kringle domains. The primer for the construction of the cDNA library is overlined. The four potential N-glycosylation sites are marked with wavy lines. In the β-chain of HGF, amino acid numbers 534 (Gln) and 673 (Tyr) correspond to the histidine and the serine in plasmin, respectively, which form the active centre for protease action.

METHODS. A long oligodeoxynucleotide probe encoding the N-terminal amino-acid sequence (1–15) of the rat HGF β-chain was synthesized on an Applied Biosystems Model 381A DNA synthesizer. This probe (44-mer) containing inosine is 3'>CAICAITTICCITAIGGITGIGTITGITGICAIC-CIACCTACCA<5'. These oligodeoxynucleotides were labelled by phosphorylation using T4 polynucleotide kinase and [γ-^{32}P]ATP (ref. 18). Rat liver double-stranded cDNA was synthesized from liver poly(A)$^+$ RNA that had been isolated from rats 10 h after they had been injected with CCl_4. A cDNA synthesis system (Amersham UK) with oligo dT primer was used and the cDNA was methylated by *Eco*RI methylase and then ligated into an *Eco*RI linker[19]. After *Eco*RI digestion, the cDNAs were ligated into *Eco*RI-digested λgt10 vector (Stratagene) and packaged *in vitro* using Gigapack Gold (Stratagene)[20]. The recombinant phages were plated on *E. coli* NM514 and a replica nitrocellulose filter prepared[21]. From 2 μg poly(A)$^+$ RNA, 2×10^6 transformants were obtained. These clones were screened by hybridization to a probe 44 bases long and containing inosine. Filters were hybridized with the ^{32}P-end-labelled 44-mer probe for 12 h at 45 °C in 5× SSC, 5× Denhardt's solution, 0.1% SDS and 100 μg ml^{-1} denatured salmon testis DNA. The filters were then washed at 50 °C in 5×SSC containing 0.1% SDS, air-dried, and autoradiographed using Fuji X-ray film. We obtained one positive clone containing the 1.4 kb *Eco*RI fragment, designated as RBC1. The human liver cDNA library was constructed from human liver poly(A)$^+$ RNA (Clontech) as before, except that cDNAs larger than 4 kb were fractionated in a 1% agarose gel, pooled, and then ligated. Recombinants (2×10^5) were screened with the ^{32}P-labelled 1.4 kb *Eco*RI fragment of RBC1 (Amersham multiprime DNA labelling system). Two clones, HBC1 and HBC25, were obtained. The cDNA library was constructed using 5'-TCATAATCTTTCAAGTCT as a primer, 6×10^5 recombinants were screened using the 0.7 kb *Eco*RI fragment prepared from HBC25 to yield 100 positive clones and the two longest clones, HAC69 and HAC102, were isolated. The cDNA inserts of the clones HAC69 and HBC25 were subcloned into M13mp18, M13mp19 and pBluescript (Stratagene) and sequenced by the dideoxy-termination method[22] using Sequenase (US Biochemicals).

corresponding to a recovery of 23% The purified HGF was reduced, carboxymethylated and fractionated by reverse-phase HPLC on a C_4-column to isolate the α- and β-chains We determined the N-terminal sequence (one-letter code) of the α- and β-chains as PLVKIKTKKVNSADECANR and VVNGIPTQTTVGWMVSLKYRNKHICGG, respectively

We employed the following strategy to isolate a cDNA encoding complete human HGF First, we cloned rat HGF cDNA using a hybridization probe designed to have a sequence corresponding to the N-terminus of the rat HGF β-chain, and then isolated human HGF cDNA using the rat HGF cDNA as probe We investigated the tissue distribution of HGF in rats to establish a good source of HGF messenger RNA and found that the livers of rats treated with CCl_4 contain large amounts of HGF To clone HGF cDNA, a cDNA library constructed in λgt10 from poly$(A)^+$ RNA extracted from the livers of CCl_4-treated rats was screened with a single 44-mer oligodeoxynucleotide whose sequence corresponded to the first 15 amino acids of the β-chain Screening 2×10^6 clones gave one positive clone with a 1 4-kilobase (kb) insert (clone RBC1) Nucleotide sequencing of this insert revealed an open reading frame predicting the translation of a 404-residue protein and a 3′-untranslated sequence (data not shown) We confirmed that the 27 N-terminal amino acids of the β-chain were included in the 233 amino acids of the rat HGF β-chain encoded by the 1 4 kb insert

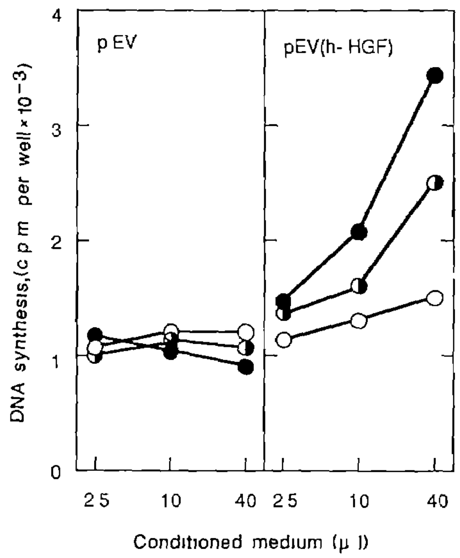

FIG 3 Expression of the cloned cDNA encoding the human HGF in COS-1 monkey kidney cells HGF activity in the conditioned medium from cultures of COS-1 cells transfected with HGF cDNA (right) and the corresponding vector without insert (left) O, 1-day culture, ◑, 2-day culture, ●, 3-day culture

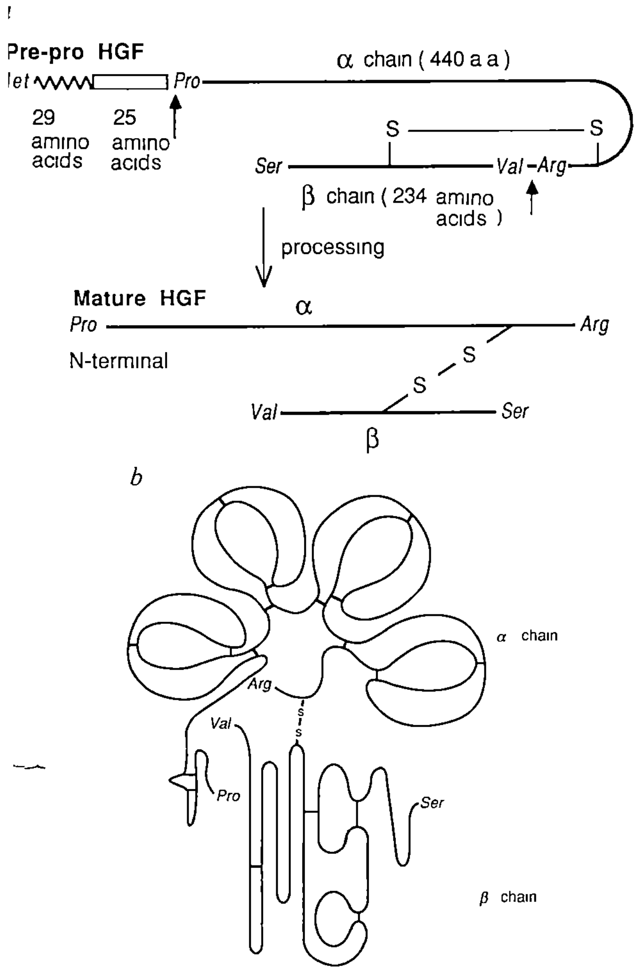
METHODS The vector pEV contains the SV40 early promoter, polyadenylation sequence and the origin of replication The human HGF cDNA (*BamHI-PstI* 2 95 kb fragment) was inserted into pEV vector downstream of the SV40 early promoter The constructed plasmid DNAs (pEV) were introduced to COS-1 cells by the DEAE-Dextran method[23] COS-1 cells were seeded at a density of 2×10^5 cells into 60 mm tissue culture plates two days before transfection After washing the plates with 20 mM Tris-HCl (pH 7 4) containing 150 mM NaCl (TBS), 10 µg plasmid DNA in TBS (600 µl) containing 500 µg ml^{-1} DEAE-dextran was used for transfection for 30 min at room temperature The transfected cells were incubated with Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal calf serum (FCS) and 100 µM chloroquine for 3 h at 37 °C, followed by treatment with DMEM containing 10% FCS and 10% dimethylsulphoxide for 2 5 min at room temperature This medium was replaced with DMEM containing 10% FCS and 50 µg ml^{-1} gentamicin and cultured for 3 days at 37 °C The culture medium was collected at 24, 48 and 72 h after transfection, and HGF activity assayed as described[24,25] Aliquots of conditioned medium (2 5, 10 or 40 µl) were added to the adult rat hepatocyte cultures (1 6 cm diameter well 0 5 ml medium) 20 h after plating, and 18 h later, ^{125}I-labelled deoxyuridine (0 3 µCi ml^{-1}) was added Six hours later, DNA synthesis was assayed by measuring the incorporation of ^{125}I-labelled deoxyuridine A purified preparation of rat HGF from platelets (2ng ml^{-1}) and saline used as controls gave 5,400 c p m and 1,200 c p m incorporation, respectively

Northern hybridization using the RBC1 clone showed that levels of rat HGF mRNA were negligible in normal liver but increased markedly in the injured livers of CCl_4-treated rats, and that the mRNA was ~6 kb in size We next investigated whether we could use human liver mRNA as a source of mRNA for human HGF cDNA cloning HGF mRNA was clearly detectable in human liver and was the same size as the rat HGF mRNA, as shown in Fig 1 A human liver cDNA library was therefore constructed in λgt10, using oligo(dT) primer The screening of 2×10^5 cDNA clones with ^{32}P-labelled RBC1 gave two positive clones (HBC1 and HBC25) and two additional cDNA clones (HAC69 and HAC102) were obtained from the unique 18-mer primer-extended cDNA library Four clones were characterized in detail and are illustrated in Fig 2*a*, together they span 6 kb which is sufficient to encode the entire mRNA that we detected by northern blotting The sequence comprises a 5′ non-coding region of 134 nucleotides, a single open reading frame of 2,184 nucleotides and 3,580 nucleotides of the 3′ non-coding region, which contains an A^+U-rich sequence (Fig 2*b*)

A polypeptide of 728 amino acids is encoded by human HGF cDNA in a single open reading frame which includes both the α- and β-chains The calculated relative molecular masses (M_r) of the human HGF pre-precursor and the mature form are 83,126 and 76,879 respectively The N-terminal amino acid of the α-chain is preceded by 54 amino acids, starting with a methionine Of these 54 amino acids, most of the first 29 are hydrophobic, which is typical of a signal sequence[7] The next 25 (amino acids 30-54) preceding the N-terminus of the α-chain constitute the pro-sequence The α-chain runs from amino acids 55 to 494, and the β-chain from 495 to 728 From the known substrate specificity of proteases, this Gln-Leu-Arg-Val sequence should be accessible to a trypsin-like protease such as plasmin or plasma kallikrein[8] After biosynthesis, the chains are separated by a trypsin-like protease at an Arg-Val site (Fig 4*a*) The predicted M_r of the α-chain, which consists of 440 amino acids, is 50,808, and for the β-chain, which consists of 234 amino acids, it is 26,089 The HGF contains four putative asparagine-linked glycosylation sites, which are located at positions 294 and 402 of the α-chain and at positions 566 and 653 of the β-chain The difference between the M_rs of the HGF subunits as determined by SDS-PAGE and those predicted from the cDNA sequence may be due to carbohydrate residues, which have been demonstrated by binding to concanavalin A-Sepharose columns (data not shown)

We demonstrated that biologically active HGF could be expressed from its cDNA in transient expression experiments in COS-1 cells As shown in Fig 3, the conditioned medium from the cells transfected with the plasmid pEV(hHGF) revealed the dose-dependent stimulation of DNA synthesis of adult rat hepatocytes in primary culture This activity was abolished by heating at 100 °C for two minutes and we found that it was additive with insulin and EGF, which suggested to us that it was attributable to HGF

We found considerable homology (38%) between the overall amino-acid sequence of the pro-HGF precursor and plasminogen[9], but neither plasminogen nor plasmin has HGF activity (data not shown) Plasminogen has 791 amino acids and contains five kringle structures, the α-chain of HGF would contain four kringle structures Prothrombin, tissue plasminogen activator, urokinase and coagulation factor XII also contain a kringle structure[10] Although the kringle domain is thought to play a part in protein-protein interaction, its physiological function is unknown On the other hand, the mature β-chain has extensive homology (37%) with a serine protease domain of plasminogen, but the histidine and serine residues of the protease active site are replaced in the HGF β-chain by glutamine and tyrosine, respectively, so HGF should have no proteolytic



IG 4 Structural features of human HGF *a*, Schematic representation of ie structure and processing of pre-pro HGF The arrows indicate the rocessing sites The wavy line and unfilled line represent the signal peptide nd pro-sequences, respectively *b*, Predicted primary structure of human GF An interchain S-S bridge is formed between Cys 487 in the α-chain nd Cys 604 in the β-chain

ctivity Other examples of amino acid replacements in the serine rotease active site include haptoglobin[11] and protein Z[12], which ave no proteolytic activity In mature HGF, Cys 604 in the β-chain and Cys 487 in the α-chain seem to form an interchain ridge in a position comparable to that of the interchain bridge ound in plasmin The predicted structure of human HGF is hown in Fig 4*b*

A marked increase in HGF-like activity has been reported in he sera of both partially hepatectomized[1 2,13] and hepatotoxin-reated rats[14 15] and of patients with fulminant hepatic failure[16] Ve find a time-dependent increase in HGF activity in rat liver fter administration of CCl_4, which reaches a maximum of about 0 times the initial level at 36 hours The level of HGF mRNA s negligible in normal rat liver, but increases dramatically in njured liver 10 hours after the administration of CCl_4 We have lemonstrated that rat liver-derived HGF has the same chemical nd biological properties as rat platelet-derived HGF (manucript in preparation) These findings indicate that the liver itself s producing HGF HGF in plasma from patients with fulminant iepatic failure is probably derived from the injured liver as uman platelets do not contain a significant amount of HGF, nlike rat platelets Thus HGF seems to be an important growth actor in the stimulation of liver regeneration after partial iepatectomy and liver injury

The availability of functionally active recombinant human GF will enable us to study the HGF receptor on hepatocytes nd the role of HGF during liver regeneration *in vivo* HGF may eventually be useful clinically for enhancing liver regeneration after surgery and in the diagnosis and treatment of hepatitis ☐

Anti-HLA-A2 antibody-enhancement of peptide association with HLA-A2 as detected by cytotoxic T lymphocytes

Helen Bodmer, Graham Ogg, Frances Gotch & Andrew McMichael

Molecular Immunology Group, Institute of Molecular Medicine,
University of Oxford, John Radcliffe Hospital, Oxford OX3 9DU, UK

MOST cytotoxic T lymphocytes (CTL) not only recognize epitopes of viral or other foreign proteins in association with class I major histocompatibility complex (MHC) molecules, but also recognize target cells sensitized with short synthetic peptides representing the epitopes[1] There is increasing evidence that these synthetic peptides associate with the class I molecule both at the cell surface and intracellularly[2] We have now investigated the effect of a monoclonal antibody specific for HLA-A2 and HLA-B17 (B57/58) molecules (antibody MA2 1)[3] on the sensitization of target cells with peptide for lysis by HLA-A2-restricted CTL Previously, anti-HLA class I monoclonal antibodies have been shown to inhibit the recognition of target cells, infected with influenza A virus, by virus-specific CTL[4,5] We find, however, that target cells treated with MA2.1 antibody can be sensitized with peptide for CTL lysis much more rapidly than untreated cells, or at >100-fold lower peptide concentration than that required for sensitization of untreated cells This implies that the antibody, which is believed to bind to one side of the peptide-binding groove, directly affects the binding of peptide to the HLA-A2 molecule at the cell surface.

Experiments using anti-HLA class I monoclonal antibodies to inhibit target-cell lysis by virus-specific CTL have demonstrated the importance of the class I molecule in MHC-restricted recognition of antigen[4,5] Most allele-specific antibodies are thought to bind to the helices on either side of the putative peptide-binding groove of class I molecules[6], thereby possibly effecting the binding of peptide to the class I molecules

We investigated the effect of antibody MA2 1, a high-affinity antibody with specificity for HLA-A2 and HLA-B17 molecules[3,7] on the association of peptide with HLA-A2-expressing target cells, as detected by HLA-A2-restricted CTL According to the crystal structure of HLA-A2 (ref 6), the critical residues for recognition by MA2 1 antibody, residues 62-66 of the α1 domain[8], are in a region important for both T-cell recognition and peptide binding Residue 63, moreover, has an interdomain contact with residue 171 of the α_2-helix[9] We have previously reported that HLA-A2-restricted CTL specific for matrix protein of the influenza A virus recognize the synthetic peptide representing residues 58-68 of matrix protein (M58-68)[10] Some of these CTL are also able to recognize synthetic peptide in association with HLA-Aw69, encoded by an allele closely related to that of HLA-A2, but which does not bind MA2 1 antibody[11]

Surprisingly, when added directly to a cytotoxicity assay, the MA2 1 antibody greatly enhanced the recognition of peptide M58-68 on autologous target cells by peptide-specific HLA-A2/Aw69 cross-restricted CTL (Fig 1*a*) This effect was consistently seen at antibody concentrations greater than 0 1 $\mu g\ ml^{-1}$ On a target cell expressing HLA-Aw69 and HLA-B57, however, no enhancement of recognition by the same CTL was seen (Fig 1*b*), even though the antibody still bound to both T cells and target cells Another HLA-A2-specific monoclonal antibody, PA2 1 (ref 12, cross-reactive with HLA-Aw69) did not show any shift in the dose-response curve for the recognition of peptides on target cells expressing either HLA-A2 or HLA-Aw69 (Fig 1*a*, *b*) The slight inhibition of recognition shown in Fig 1*b* with MA2 1 antibody could be due to effects on the T cell, because incubation of HLA-A2-restricted CTL in high concentrations of MA2 1 antibody can inhibit their ability to lyse target cells (data not shown) The enhancement is not unique to this peptide, as similar effects have been shown for the recognition of a different peptide, from the nucleoprotein of influenza B virus, recognized by specific HLA-A2-restricted CTL (data not shown, and P Robbins, personal communication)

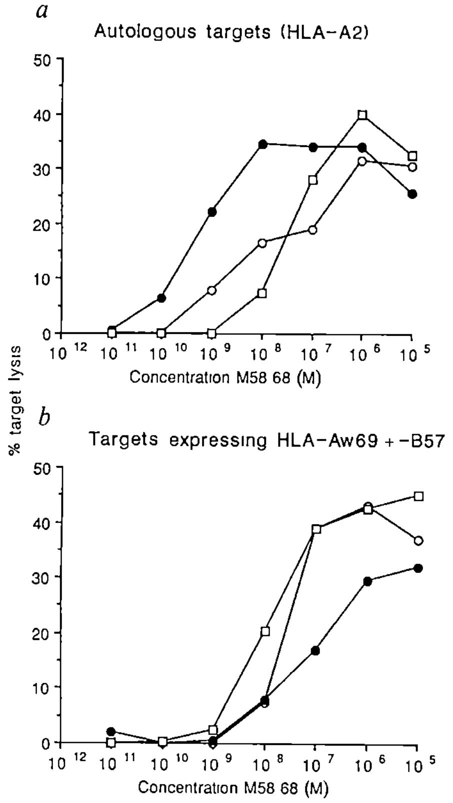

FIG 1 The anti-HLA-A2 antibody, MA2 1, enhances recognition of peptide by matrix-specific HLA-A2/Aw69 cross-restricted CTL on HLA-A2—but not HLA-Aw69—expressing target cells Effect of the presence of antibodies MA2 1 or PA2 1 on the dose-response curve of recognition of the peptide M58-68 of influenza matrix protein by CTL clone 1A10 from the donor JM (A2, 2, B15, 51 DR4, 4) on *a*, autologous target cells or *b*, a target cell MAL-NF (A1, w69, B35, 57, DR7, 10) which binds MA2 1 antibody on its B57 allele product Both peptide and antibody (1 25 $\mu g\ ml^{-1}$) were added directly to the assay Whereas MA2 1 antibody enhanced recognition of peptide by 10- to 100-fold on autologous cells, a small degree of inhibition was seen with the HLA-Aw69 expressing cells Antibody PA2 1 did not produce a shift in dose-response curve in either case Killer target ratio (K T)=1 8 Lysis in the absence of peptide, <2 3% ○, No antibody, ●, MA2 1, □, PA2 1

METHODS Influenza A virus matrix peptide M58-68 (Gly-Ile-Leu-Gly-Phe-Val-Phe-Thr-Leu-Thr-Val) was synthesized and donated by Dr J Rothbard (ICRF, London) CTL clone 1A10 was derived as previously described[11] Purified monoclonal antibodies MA2 1 (ref 3) and PA2 1 (ref 12) were used, and were donated by Dr J G Bodmer (ICRF, London) ^{51}Chromium-release cytotoxicity assay Epstein-Barr virus-transformed lymphoblastoid cells (BCL), used as target cells, were labelled with ^{51}Cr and added to the assay with CTL and diluted peptide and antibody, where appropriate, for 4 h in round-bottomed 96-well plates Percentage target lysis was calculated from the formula (E − M/D − M) × 100 E, experimental ^{51}Cr release, M, release in presence of culture medium (always <18%), D, release by 5% Triton X-100

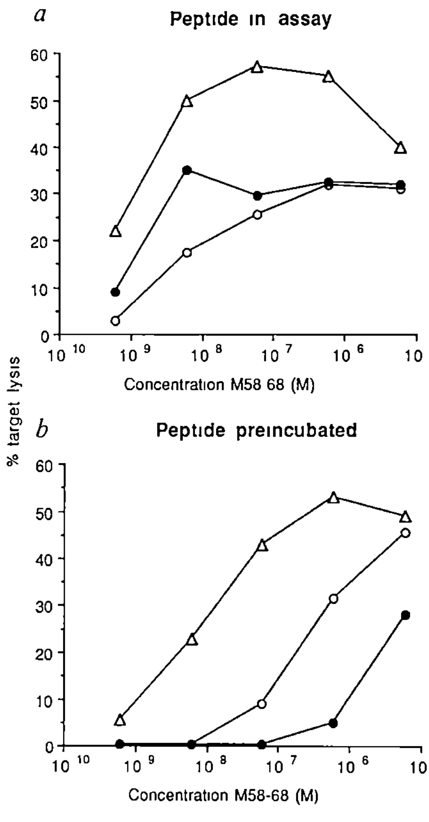

FIG 2 Optimum enhancement of recognition by MA2 1 antibody occurred when target cells were exposed to antibody before or during exposure to peptide, and when MA2 1 antibody was not present in the assay MA2 1 antibody inhibited recognition of target cells which had been pretreated with peptide CTL clone 1A10-recognition of peptide M58-68 on autologous BCL target cells (K T=3) was affected differently depending on the order of exposure of BCL to MA2 1 antibody or peptide *a*, Peptide M58-68 titrated in the assay at the concentrations shown, target cells were either untreated (○) or pretreated with MA2 1 antibody (1 $\mu g\ ml^{-1}$) (△), MA2 1 antibody added directly to the assays (●) Lysis in the absence of peptide, <1% *b*, Target cells were pretreated with peptide M58-68 at the concentrations shown ○, No antibody, △, simultaneous pretreatment with MA2 1 antibody and peptide, ●, BCL pretreated with peptide with MA2 1 antibody added directly to assay

METHODS As in Fig 1, except that target cells pretreated with peptide were incubated, in dilution of peptide shown, for 1 h and then washed three times before inclusion in the assay

These results show that the enhancement of peptide recognition by MA2 1 antibody is due to binding to the peptide-presenting HLA-A2 of the target cell rather than to HLA-A2 on the T cell, or to an irrelevant allele product (that is, non-presenting) on the target cell To optimize the enhancement, various conditions of exposure to peptide and antibody were investigated Figure 2*a* shows the results of experiments in which peptide was titrated in the CTL assay, and target cells were either pretreated with antibody, or antibody was added directly to the assay Pretreatment with antibody enhanced peptide recognition ~100-fold with greatly increased lysis, whereas adding antibody to the assay only gave a modest increase Figure 2*b* shows the results of experiments in which target cells were pretreated with peptide, and antibody was either added with the peptide or added directly to the assay Whereas pretreatment with antibody again produced nearly 100-fold enhancement of peptide recognition, addition of MA2 1 antibody to the assay inhibited the recognition of the peptide-treated target cells, similar to the inhibition of recognition of virus-infected cells (refs 4 and 5, and data not shown) Thus, MA2 1 antibody has a dual action, first, it enhances peptide association at the level of HLA-A2 on the target cell, and second, it interferes with T-cell recognition when it is present in the assay

Because both MA2 1 and PA2 1 are IgG1 monoclonal antibodies[13], and only MA2 1 antibody enhances peptide recognition, it is unlikely that the IgG1 Fc receptor mediates the effect As antibody divalency could be important, either by crosslinking target cells and CTL, or by crosslinking HLA-A2 on the target-cell surface, the effects of F(ab')$_2$ and Fab' fragments of MA2 1 antibody were assessed Target cells were pretreated with MA2 1 antibody or its fragments, using PA2 1 antibody as a control CTL (Fig 3*a*) were able to recognize peptide at 1,000-fold lower concentrations on HLA-A2-matched target cells pretreated with either whole MA2 1 antibody or its F(ab')$_2$ fragment relative to control The enhancement seen with Fab' was much less, although consistent in five different experiments, and could be due to lower avidity of the monovalent fragment[7] But a 10-fold enhancement of peptide recognition was seen with target cells incubated simultaneously with peptide and Fab' (Fig 2*b*) This effect is unlikely to be due to contamination of the sample with divalent fragments, because SDS-PAGE of a radio-iodinated sample did not show any trace of either whole IgG or F(ab')$_2$ (Fig 3*c*)

The simplest explanation of the data presented here is that the presence of MA2 1 antibody on a target cell enables HLA-A2 to bind peptide at the cell surface more efficiently To test this hypothesis, the kinetics of target-cell sensitization with peptide were studied on untreated and MA2 1 antibody-pretreated cells Targets were pulsed with 5 µM peptide (Fig 4*a*) in the absence of antibody, maximum lysis was not reached by 20 min of incubation with peptide But when the target cell was saturated in antibody, a 30-s peptide pulse was sufficient to obtain almost maximal lysis The lower concentration of 0 05 µM peptide was insufficient to give any lysis in the absence of antibody, but with the antibody-treated cells, the lysis was as effective as it was at the 100-fold greater peptide concentration in the absence of antibody

The rapidity of target sensitization in the presence of antibody

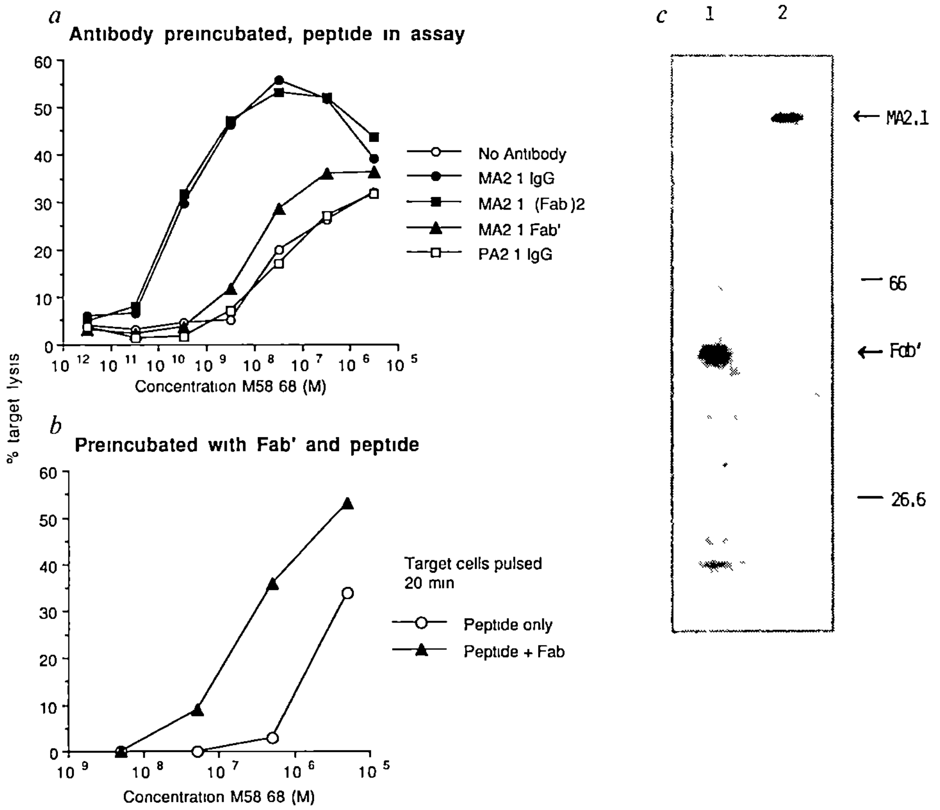

FIG 3 Fragments of MA2 1 antibody are able to enhance recognition of peptide Effect of MA2 1 antibody or its Fab' or F(ab')$_2$ fragments (1 µg ml^{-1}, that is, equivalent numbers of combining sites for Fab' and F(ab')$_2$) on the dose–response curve of recognition of peptide M58–68 of the polyclonal CTL line JM 22 on HLA-A2-matched BCL target cells (A2, 11, B54, 0, DR4, 12) K T=2 Lysis in the absence of peptide, <3 5% *a*, BCL target cells were pretreated in antibody MA2 1 or PA2 1 or fragment (1 µg ml^{-1}) as indicated and washed before inclusion in the assay Both MA2 1 antibody and its F(ab')$_2$ fragment caused a 100- to 1,000-fold enhancement of recognition, the Fab' fragment enhanced recognition by ~10-fold No enhancement was seen after preincubation with PA2 1 *b*, Recognition of autologous target cells by JM 22CTL was enhanced 10-fold (K T=2) after pretreatment of the target cells with a simultaneous pulse of peptide and Fab' (5 µg ml^{-1}) Target cells were either pulsed with peptide alone at the concentrations shown, or with peptide with MA2 1 Fab', for 20 min, followed by three washes before addition to the assay No free peptide or antibody fragment was added to the assay *c*, SDS-PAGE analysis of iodinated samples of the Fab' fragment of MA2 1 antibody (lane 1) or whole MA2 1 antibody (lane 2), 10% polyacrylamide gel, under nonreducing conditions Relative molecular mass markers indicated (×10^{-3})

METHODS JM 22 CTL were derived and maintained as previously described for other polyclonal matrix-specific lines[10] F(ab')$_2$ and Fab' fragments of MA2 1 antibody were prepared from purified antibody by pepsin digestion, according to the method previously described for mouse IgG1 monoclonal antibodies[13] Purity of fragments was established by SDS-PAGE (see *c*, and data not shown) Fragments were still able to bind HLA-A2 specifically as indicated by indirect fluorescence binding (data not shown) ^{51}Cr release assay As for Fig 1 except for *a*, BCL target cells were pretreated in antibody or fragments for 1 h and then washed three times before inclusion in the assay *b*, Pretreatment of cells was for 20 min SDS-PAGE of iodinated Fab' and whole antibody Whole antibody or Fab' fragment (~10 µg) was iodinated by addition of ^{125}I (0 5 µCi) in Chloramine-T (2 4 g ml^{-1}) for 2 min The reaction was stopped with saturated tyrosine, and the iodinated fraction was separated on a PD-10 column Each sample (10^6 c p m) were analysed on a 10% acrylamide gell by SDS-PAGE under nonreducing conditions The gel was fixed, stained, dried and exposed to X-ray film makes an interaction at the cell surface a likely explanation for the enhancement of peptide recognition This is supported by the fact that pretreatment of target cells with MA2 1 antibody before virus infection does not enhance the recognition of these cells (data not shown) Up-regulation of expression of class I molecules or HLA-A2 is an unlikely explanation, both because cycloheximide (an inhibitor of protein synthesis) has no effect on the enhancement, and antibody-binding studies have not shown an increase in cell surface HLA-A2 after MA2 1 antibody treatment (data not shown) The experiment represented in Fig 1*b* rules out the crosslinking of T cell and target as a possible explanation

The cell-surface effect could result from an increase in the number of peptide molecules bound in an immunogenic conformation, or from an increase in the total number of peptide molecules bound to HLA-A2 If, as predicted by the critical binding residues 62–66, MA2 1 antibody binds at the side of the groove in HLA-A2, the antibody could stabilize a conformation of A2 that allows freer exchange of peptide As the T-cell receptor probably binds at a similar site, it is possible that the receptor could also facilitate antigenic peptide exchange This could be an important factor in the dissociation of the T-ce receptor–peptide–MHC complex once the T cell has bee triggered

These experiments demonstrate that peptide can rapid associate with HLA-A2 at the surface of the cell in the presen of MA2 1 The antibody MA2 1 could be a useful tool in th preparation of a specific peptide with HLA-A2 for structur studies

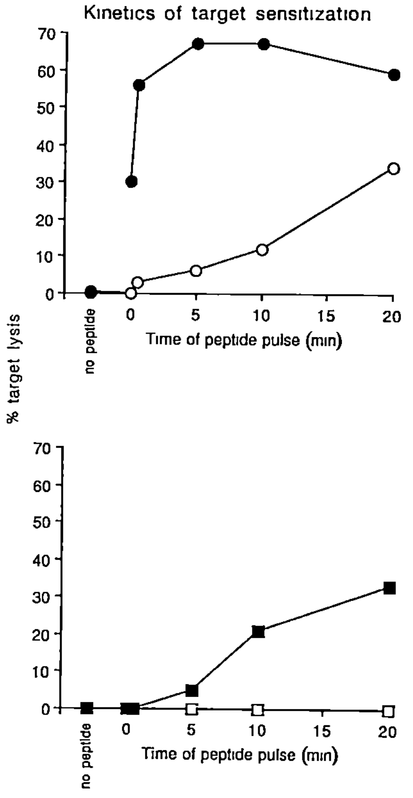

FIG 4 Target sensitization with peptide occurs much more rapidly and at lower concentrations of peptide on target cells for target cells pretreated with MA2 1 antibody (●, ■) compared with untreated cells (○, □) Lysis by JM 22 CTL (K T=2) of autologous JM BCL target cells which either had been pretreated with MA2 1 (5 μg ml^{-1}) or had not been treated, were pulsed with peptide M58-68 (5 μM above, 0 05 μM, below) for various time intervals from 30 s to 20 min

METHODS JM 22 CTL and ^{51}Cr-release assay as described in other figure legends, except for preparation of target cells, which were labelled with ^{51}Cr and either treated with MA2 1 (5 μg ml^{-1}) or not treated, for 1 h Washed cells were then pulsed with peptide for the appropriate time interval followed by an immediate 100-fold dilution in serum-free medium at 4 °C and then washed twice in RPMI-1640 at 4 °C followed by a further wash in medium containing 10% FCS at room temperature Cells were then diluted and added to the assay in the usual way Time zero represents the lysis due to peptide which associated with the cells as a result of the 100-fold dilution of peptide M58–68 in the first wash at 4 °C Spontaneous release of ^{51}Cr in the absence of CTL was <17%

Insertion of cutinase gene into a wound pathogen enables it to infect intact host

M. B. Dickman*, G. K. Podila† & P. E. Kolattukudy†‡

* Department of Plant Pathology, University of Nebraska, Lincoln, Nebraska 68583, USA
† Ohio State Biotechnology Center, The Ohio State University, Columbus, Ohio 43210, USA

MANY phytopathogenic fungi must breach the intact plant cuticle to successfully invade and colonize their hosts. It has been suggested that cutinase, an extracellular enzyme secreted by many fungi, is essential for infection in some host–pathogen interactions Chemical or immunological inhibition of cutinase protects the host from infection[1,2]. We have cloned and characterized the cutinase complementary DNA and gene from *Fusarium solani* f. sp. *pisi*[3,4], a pea pathogen. A construct containing the cutinase coding region and extensive portions of the 5′ and 3′-flanking regions from the *Fusarium* genome was transferred into another phytopathogenic Ascomycete, *Mycosphaerella* spp , a parasitic fungus that affects papaya fruits only if the fruit skin is mechanically breached before inoculation[5]. Here we describe the introduction of the *Fusarium* cutinase gene into *Mycosphaerella* to yield transformants in which this gene is inducible by cutin hydrolysate. We demonstrate that these transformants of the wound-requiring fungus have the capacity to infect intact papaya fruits, and that this infection can be prevented by antibodies against *Fusarium* cutinase.

Cutin, a biopolyester, is the chief structural component of plant cuticle[6] Fungal contact with this polymer acts as a signal to induce cutinase production by the spores[7] Chemically prepared cutin hydrolysate can also induce the cutinase gene, transcripts being detectable within fifteen minutes after the addition of inducer[7] This induction allows the fungus to breach the cuticular barrier and penetrate into the host *Mycosphaerella* spp is unable to penetrate the outer defensive barrier of papaya fruits but can infect the fruits through wounds To test whether this limitation of the pathogen could be overcome by the acquisi-

Our chief finding, therefore, is that an absence of CETP results rom a single base change in the conserved splice donor site in subject (S.Y.) and his sister (K.H.), both of whom have narkedly increased and enlarged HDL. Furthermore, there were educed levels of CETP in the children, obligate heterozygotes vho carry the defect. They also have about half the normal evels of CETP and moderately increased or enlarged HDL. The nagnitude of the increase in HDL (4-6 times normal) in S.Y. nd his sister K.H. is surprising, and indicates that CETP is of najor importance in HDL catabolism, influencing the size, omposition and quantity of HDL. The mechanism leading to he increase in the HDL protein apoA-I in S.Y. and K.H. (Table) is unclear, but could result from slower catabolism of their greatly enlarged HDL particles. It is also notable that low-density lipoproteins (LDL) were decreased in S.Y. and K.H.[4], which is shown by a lack of Sudan Black staining in the LDL region (Fig. 2*a*). This finding indicates that the normal formation of LDL requires CETP. There are no obvious clinical manifestations of CETP deficiency in S.Y., his sister or the children[4]. The lipoprotein profile associated with human CETP deficiency (that is, high HDL and low LDL) has low atherogenic potential, raising the possibility that CETP inhibitors could be used as anti-atherogenic drugs. Indeed, the lipoprotein profile found in human CETP deficiency resembles that of species that lack CETP activity in their plasma (rats, dogs and pigs) and which are relatively resistant to atherosclerosis[2]. □

elaware 19880-0328, USA

THE way in which proteins attain and maintain their final form s of fundamental importance. Recent work has focused on the role of a set of ubiquitous proteins, termed chaperonins[1], in the ssembly of phage[2] and multisubunit proteins[3,4]. The range of haperonin action is unknown; they could interact with most ellular polypeptides or have a limited subset of protein partners. Included in the chaperonin family is the essential heat-shock regulated *Escherichia coli groEL* gene product[1,5,6]. Overexpression of the *groE* operon in *E. coli* causes enhanced assembly f heterologously expressed ribulose bisphosphate carboxylase subunits[3] and suppresses the heat-sensitive mutant phenotype of several *dnaA* alleles[7,8]. It has been inferred that suppression of eat-sensitive mutations is confined to *dnaA* alleles and that this onfinement could reflect an interaction between the *groE* operon roducts and a *dnaA* protein aggregate at the replication origin[7,9]. We now report that multiple copies of the *groE* operon suppress mutations in genes encoding several diverse proteins. Our data indicate a general role for the *groE* operon products, the GroEL and GroES proteins[10], in the folding–assembly pathways of many proteins.

It has been proposed that complexes of enzymes involved in sequential metabolic reactions are common in cells[11]. To investigate if enzymes of a biosynthetic pathway are part of a weakly associated *in vivo* supramolecular structure, we isolated heat-sensitive mutations in the major *ilv* operon of *Salmonella typhimurium* (D. Smulski, T.K.V.D. and R.A.L., unpublished results) that confer a conditional growth requirement for isoleucine and/or valine. This was achieved by using a localized hydroxylamine mutagenesis protocol[12]. It was expected that overexpression of the *groE* operon products might be able to correct growth defects by forcing either the folding or assembly of recalcitrant mutant polypeptides. The auxotrophic requirements of one mutation in *ilvGM* and two mutations in *ilvE*, encoding the multimeric enzymes acetolactate synthase II and transaminase B, respectively, were suppressed by the multicopy plasmid bearing the *groE* operon (Table 1). These data indicated that mutations in genes encoding biosynthetic enzymes can be suppressed by overexpression of the *groE* operon products.

We then investigated whether overexpression of the *groE* operon products could suppress mutations in the histidine (*his*) operon of *S. typhimurium* (Table 1). Heat-sensitive[13,14], cold-sensitive[14] and temperature-independent[13] auxotrophic missense mutations in the *his* operon were examined. Many, but not all, heat-sensitive *hisD*, *hisC* and *hisB* alleles were suppressed by *groE* over-expression (Table 1); these genes encode, respectively, histidinol dehydrogenase, histidinol-phosphate aminotransferase and the bifunctional protein imidazoleglycerol phosphate dehydratase—histidinol phosphate phosphatase[15]. Suppression of cold-sensitive and temperature-independent alleles has so far not been observed in the *his* system (Table 1).

We quantitated the suppression of the *hisD6592* allele by *groE* overexpression with a sensitive radiochemical assay[16], performed at 37 °C, of histidinol dehydrogenase activity present in toluene-permeablized cells grown at the restrictive temperature of 37 °C in minimal medium E (ref. 17) supplemented with excess (0.64 mM) L-histidine. Equivalent repressed levels of histidine biosynthetic enzymes are produced in both auxotrophs and prototrophs under these conditions[15]. Specific activities thus reflect differences unrelated to transcription. A strain containing the *hisD6592* allele and the control plasmid pTG10, had undetectable enzyme activity (<0.5% of wild-type specific activity) whereas a strain containing the same *hisD* allele and the plasmid overexpressing *groESL* (ref. 3) contained 3%

Plasmids pTG10 (control)[3] and pGroESL (*groES*$^+$ *groEL*$^+$)[3] were transformed into a restriction-deficient strain of *S. typhimurium* LT2, TR5878 (ref. 28) selecting for chloramphenicol resistance. Phage P22-mediated generalized transduction[17,29] was used to transfer the plasmid to the various *S. typhimurium* mutants. Growth of the *S. typhimurium* recombinants was tested at 18, 30, 37, 39 and 42 °C on minimal medium E supplemented with 0.4% glucose[17]. Introduction of pTG10 did not allow growth of any mutant at the restrictive temperature. (+), Strain containing plasmid pGroESL grew at temperatures restrictive for the growth of the otherwise isogenic plasmid pTG10 containing strain. Suppression of P22 mutations was tested by assaying plaque formation on lawns of *S. typhimurium* DB7136 (ref. 30) derivatives containing either plasmids pTG10 or pGroESL incubated at the restrictive temperature. Transformation was used to introduce the plasmids into *E. coli* strains. With the exception of *secY24*, suppression tests of all *E. coli* mutations was scored on chloramphenicol-supplemented LB plates[17] at 42 °C. For *secY24*-bearing *E. coli* strains[21], suppression tests were performed with the *groES*$^+$*EL*$^+$-bearing plasmid pOF39 (ref. 7) on minimal M9 medium[17] supplemented with glucose and ampicillin. Each *S. typhimurium* and *E. coli* strain contained a wild-type chromosomal copy of the *groE* operon. Abbreviations: CS, Cold-sensitive; HS, heat-sensitive; TI, temperature-independent; NA, not applicable.

[*] The *his* alleles, numbered below 1,000 are reviewed in ref. 13 whereas those numbered above 1,000 are described in ref. 14.

[†] The *ilv* alleles have not been reported previously.

of the activity present in the wild-type strain containing the plasmid overexpressing *groESL*.

All but one of the enzymes involved in histidine biosynthesis are multimeric[15]. Only two heat-sensitive alleles of *hisA* (ref. 14), specifying the monomeric protein phosphoribosylformimino-5-amino-1-phosphoribosyl-4-imidazolecarboxamide isomerase[15] exist; neither was suppressed by the multicopy *groE*-bearing plasmid (Table 1). Heat-sensitive mutants caused by alteration of monomeric proteins, although rare, have been described for several aminoacyl-tRNA synthetases in *E. coli*[18]. The proteins of this family display diverse quaternary structures (α, α_2, $\alpha\beta$, $\alpha_2\beta_2$, α_4)[19]. The *groE*-bearing plasmid did not suppress heat-sensitive growth defects caused by mutations in *alaS*, *glnS*, *leuS*, *metG* and *serS*, which are structural gene encoding, respectively, alanyl-(α_4), glutaminyl-(α), leucyl-(α) methionyl-(α_2) and seryl-(α_2) tRNA synthetases in *E. co* (Table 1).

Protein translocation involves interactions among sever components. Among mutations affecting the mitochondrial protein import machinery in *Saccharomyces cerevisiae* are allele of *MIF4*, which encodes a protein homologue of *E. coli* GroEL[4] We tested the ability of the *groE*-bearing plasmid to suppres heat-sensitive growth (Fig. 1; Table 1) and secretion (A.A.G. unpublished data) defects caused by the *secA51*[20] and *secY24*[2] alleles of *E. coli*. Suppression of both alleles was observed (Table 1), indicating that the suppression mechanism is gene-independent in *E. coli* as well as in *S. typhimurium*. The presence o pGroESL had no effect on the growth of a strain containing conditionally lethal amber mutation in gene *X* upstream of *sec* (A.A.G., unpublished data); the lethality is due to the pola effect of the mutation on *secA*, resulting in the absence of th *secA* protein[20]. This implies that the *secA* protein must be presen for the suppression of the secretion defect and that *groE* overexpression cannot bypass this requirement.

Can mutations altering structural proteins, rather tha enzymes, be suppressed by overexpression of the *groE* operon products. Gene *9* of *Salmonella* phage P22 encodes a polypeptide that trimerizes to form the phage's tail spike, six of which are attached to each phage particle[22]. Many extensively characterized heat-sensitive protein-folding mutations of gene *9* exist[22,23]. Phages containing such mutations do not plaque on wild-type *S. typhimurium* at the restrictive temperature. We determined the ability of these mutants to form plaques on strains containing either a control or the *groE* multicopy plasmid at the restrictive temperature (Table 1). Several mutations were suppressed.

We characterized the suppression of the P22 *9tsfH304* mutation more fully. The efficiency of plating of this mutant at 39 °C versus 30 °C on a strain containing a control plasmid[3] was less than 10^{-4}. By contrast, the efficiency of plating on a host containing the plasmid overexpressing *groESL* (ref. 3) was 0.1. At 30 °C we observed a burst size of ~200 with either host. Infection of the strain overexpressing *groESL* with the mutant phage resulted in a burst of six plaque-forming units (PFU) at 39 °C; a burst of 0.4 PFU was observed when the host contained the control plasmid.

The nucleotide and corresponding deduced amino-acid sequences of the *groE*-suppressed phage P22 gene *9* (refs 22,

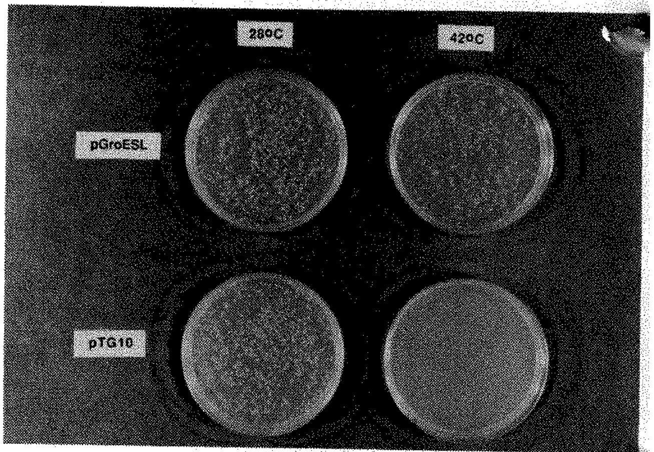

FIG. 1 Suppression of the heat-sensitive phenotype of a *secA51* strain. Strain MM52 (*secA51*)[20] was transformed with either plasmid pTG10 (*groES*$^-$*groEL*$^-$) or plasmid pGroESL (*groES*$^+$*groEL*$^+$) selecting for chloramphenicol resistance. Recombinants were plated for single colonies on antibiotic-containing LB medium at the indicated temperatures. The presence of plasmid pGroESL suppressed the heat-sensitive phenotype of the *secA51* mutant.

TABLE 2 Nucleotide sequences and deduced amino-acid sequences of suppressible alleles

Allele	Codon change	Amino-acid change	Amino-acid residue	Ref.
secA51	CTG → CCG	Leu → Pro	43	20
secY24	GGT → GAT	Gly → Asp	240	21
P22 *9 tsfU34*	AAG → GAG	Lys → Glu	163	23
P22 *9 tsfH304*	GGA → AGA	Gly → Arg	244	22
P22 *9 tsfU3*	GAA → GTA	Glu → Val	309	23
P22 *9 tsfU8*	GAA → AAA	Glu → Lys	344	23

The *E. coli secA*, *secY* and the phage P22 gene *9* proteins are of 901, 443 and 666 amino-acid residues, respectively[20-23].

23) and the *sec* alleles[20,21] are known (Table 2). At the protein level, these gene *9* transition and transversion mutations cause replacement of an acidic side chain by a basic one (glutamic acid → lysine) and a basic R-group by an acidic one (lysine → glutamic acid), loss of a negative charge (glutamic acid → valine) and substitution of a bulky positively charged side chain for a proton (glycine → arginine). The *secA* mutation substitutes the imino acid proline in place of leucine, whereas the *secY* allele results in the substitution of the acidic side chain of aspartic acid for the proton of glycine. Proposed suppression mechanisms must be consistent with the wide variety of suppressible alleles.

Suppression of *dnaA* alleles[7,8], phage λ morphogenesis[10], and ribulose bisphosphate carboxylase assembly[3], require both *groEL* and *groES*. Both *groE* genes were also needed to mediate suppression of the mutations used in our study. Plasmids expressing either *groEL* or *groES* were unable to suppress representative alleles of gene *9*, *hisD*, *hisC*, *ilvGM* and *secA* responsive to the intact *groESL* operon (Table 3).

There are several mechanisms by which multiple copies of *groE* could act as a general suppressor of heat-sensitive and perhaps other missense mutations. *GroE* operon products could alter the translational fidelity by their interaction with the ribosome[24], or reduce protein degradation by having an antiproteolytic role, or modulate transcription rate, translation rate or ionic strength[14]. But *groE*-mediated translational misreading is unlikely to be a common means of suppression, because misreading, induced by the presence of aminoglycoside antibiotics, does not allow growth of the *groE*-suppressible *hisC15* mutant[25]. Also, the broad spectrum of suppressible alleles (Table 2) precludes codon-specific mechanisms of informational suppression. And because protein degradation is decreased in a *groEL* mutant of *E. coli*[26], it is unlikely that GroE over-production antagonizes degradation. Elevated transcription or translation of target genes also cannot explain the observed suppression, because expression of the *Salmonella his* and *ilv* operons is not increased by the presence of the multicopy *groE*-bearing plasmid pGroESL (R.A.L., unpublished observations). Finally, the *groE*-suppressible *ilvGM3139* allele is not responsive to phenotypic suppression by sodium chloride supplementation[14] (T.K.V.D., unpublished observations), indicating that elevation of the internal ionic strength cannot be a common means of suppressing the *groE*-responsive heat-sensitive mutations. Thus, the explanation most consistent with present views[1,27] and our data is that overexpressed *groE* gene products directly interact with the mutant proteins, allowing them to achieve their active conformations. Such interactions could reflect a normal association of the GroE proteins with the translation products of many genes, including wild-type versions of the suppressed alleles. □

TABLE 3 Suppression requires *groES* and *groEL*

	Growth in the presence of:			
Allele	pTG10 (groES$^-$L$^-$)	pGroEL (groES$^-$L$^+$)	pGroES (groES$^+$L$^-$)	pGroESL (groES$^+$L$^+$)
hisC6595	−	−	−	+
hisD6592	−	−	−	+
ilvGM3139	−	−	−	+
secA51	−	−	−	+
P22 *9 tsfH304*	−	−	−	+

Plasmid pGroES was constructed by ligating the small *Eco*RI restriction fragment from plasmid pS4 (ref. 7) into the *Eco*RI site of the polylinker present in pTG10 (ref. 3). Plasmid pGroES and the other listed plasmids[3] were introduced into a variety of strains carrying the indicated chromosomal mutation and the host for phage P22 growth, DB7136, as described in the legend to Table 1. Conditions to test suppression were as described in Table 1.

Identification of a novel translation factor necessary for the incorporation of selenocysteine into protein

Karl Forchhammer, Walfred Leinfelder & August Böck

Lehrstuhl für Mikrobiologie der Universität, Maria-Ward-Strasse 1a,
D-8000 München 19, FRG

DURING the biosynthesis of selenoproteins in both prokaryotes and eukaryotes, selenocysteine is cotranslationally incorporated into the nascent polypeptide chain[1,2] through a process directed by a UGA codon that normally functions as a stop codon[3-5]. Recently, four genes have been identified whose products are required for selenocysteine incorporation in *Escherichia coli*[6]. One of these genes, *selC*, codes for a novel transfer RNA species (tRNA^{UCA}) that accepts serine and cotranslationally inserts selenocysteine by recognizing the specific UGA codon[7]. The serine residue attached to this tRNA is converted to selenocysteine in a reaction dependent on functional *selA* and *selD* gene products[8]. By contrast, the *selB* gene product (SELB) is not required until after selenocysteyl-tRNA biosynthesis[8]. Here we present evidence indicating that SELB is a novel translation factor. The deduced

amino-acid sequence of SELB exhibits extensive homology with the sequences of the translation initiation factor-2 (IF-2) and elongation factor Tu (EF-Tu). Furthermore, purified SELB protein binds guanine nucleotides in a 1:1 molar ratio and specifically complexes selenocysteyl-$\mathrm{tRNA}^{\mathrm{UCA}}$, but does not interact with seryl-$\mathrm{tRNA}^{\mathrm{UCA}}$. Thus, SELB could be an amino acid-specific elongation factor, replacing EF-Tu in a special translational step.

Functional SELB protein is absolutely required for translation of the selenocysteine-specific UGA codon in the *fdhF* messenger RNA (ref. 6, and unpublished results). We first determined the nucleotide sequence of the *selB* gene (Fig. 1), and found that it potentially encodes a protein of relative molecular mass 68,800 (M_r 68.8K) consisting of 614 amino acids. Computer-assisted analysis of the amino-acid sequence revealed a striking similarity of the N-terminal 244 amino acids to the sequence of the two translation factors EF-Tu and IF-2 (Fig. 2). It is of interest that the homologous region between SELB and EF-Tu corresponds to the segment of primary structure that also is conserved between EF-Tu and IF-2. In contrast to all G proteins identified so far, SELB shows one unique deviation in its guanine-nucleotide-binding motif[9]—the universal asparagine residue (position 135 in EF-Tu), which forms a hydrogen bond with the keto group of the guanine ring[10], is replaced by threonine. Sequence similarity was also found between SELB and several other G proteins, particularly EF-G, LEPA and p21. In these cases, however, similarity is restricted to the first 120 amino acids in SELB, corresponding to the G domain of EF-Tu (data not shown).

EF-Tu and IF-2 share the property of binding guanine nucleotides and aminoacyl-tRNA. If it is assumed that this function is associated with the conserved domain, then it might be anticipated that SELB exhibits similar properties. To examine this possibility, the *selB* gene product was overproduced in a T7 promoter expression system and purified (K.F., K. P. Rücknagel and A.B., manuscript in preparation). We then used equilibrium dialysis for nucleotide-binding studies with purified SELB (Fig. 3). The SELB protein bound guanine nucleotides in a 1:1 molar ratio. The dissociation constants were calculated to be 10 μM for SELB-GDP and 1.7 μM for SELB-GTP (Fig. 3*a*, *b*). Binding is specific for guanine nucleotides, because the addition of a 10-fold excess of various other nucleotides did not result in competition for binding of $[^3\mathrm{H}]$GTP (Fig. 3*c*); binding of $[^3\mathrm{H}]$GDP could only be quenched by GTP (data not shown). Thus, SELB binds GDP with an affinity similar to that exhibited by IF-2 (ref. 11). This deviates significantly from the affinity of EF-Tu for GDP, which is three orders of magnitude greater[12]. The trend is reversed for GTP binding; SELB and EF-Tu have similar affinities for GTP, whereas the affinity of IF-2 for GTP is lower by a factor of ~100 (refs 11, 12).

To examine whether SELB also interacts with *selC*-encoded $\mathrm{tRNA}^{\mathrm{UCA}}$, we purified the latter from a strain carrying the gene on a multicopy plasmid[23]. We analysed complex formation by determining the protection of the tRNA by SELB either against alkaline hydrolysis of the aminoacyl-tRNA ester bond[13,14], or against enzymatic cleavage of the tRNA by RNase[15]. After ligation to $\mathrm{tRNA}^{\mathrm{UCA}}$, L-serine was converted *in vitro* to selenocysteyl-tRNA by using extracts from cells overproducing the *selA* and *selD* gene products[23]. We then attempted to chemically deacylate the recovered selenocysteyl-tRNA in the presence or absence of SELB. We found a significant degree of protection of the tRNA against hydrolysis in the presence of SELB. This effect was independent of the addition of guanine nucleotides (Fig. 4*a*). By contrast, we could not detect any protection from deacylation when seryl-$\mathrm{tRNA}^{\mathrm{UCA}}$ was used in the same assay (Fig. 4*b*). We also found no protection with any other aminoacyl-tRNA tested (data not shown). Similar results were obtained when we assayed complex formation using the RNase-protection method[15]. SELB specifically protected selenocysteyl-$\mathrm{tRNA}^{\mathrm{UCA}}$ (Fig. 4*c*, *d*). Again, this effect did not require the presence of guanine nucleotides.

FIG. 1 Nucleotide sequence of the *selB* gene and its derived amino-acid sequence. The 2.1 kilobase (kb) insert of plasmid pWL144 (ref. 6) containing the *selB* gene was sequenced by the method of Maxam and Gilbert[16] using either restriction sites within the plasmid or the endpoints of nested Bal31 deletion clones. The putative Shine–Dalgarno sequence is underlined and the termination codon is indicated by asterisks. The sequence data are deposited in the EMBL database under the accession number X16644.

FIG. 2 Comparison of the N-terminal amino-acid sequence of SELB with the amino-acid sequences of translation factors EF-Tu (ref. 17) and IF-2 (ref. 18) from *E. coli* (single-letter amino-acid code). Identical or chemically similar amino acids are boxed, and the following amino acids were considered as similar: D and E; N and Q; K and R; S and T; I, L, M and V; and F, W and Y. Five regions conserved in G proteins[19] are indicated by horizontal bars. The solid bars correspond to regions directly involved in binding GTP as defined by X-ray crystallography for EF-Tu (ref. 10). The dashed line indicates a region in the sequence that is conserved only among elongation factors[19] and is proposed to be involved in GTPase activity[20]. Amino acids probably located near the aminoacyl-tRNA-binding site of EF-Tu as shown by crosslinking and chemical-modification studies[21,22], are indicated by *. The number 112 indicates the position of the highly conserved asparagine residue of G proteins replaced by threonine in the SELB sequence.

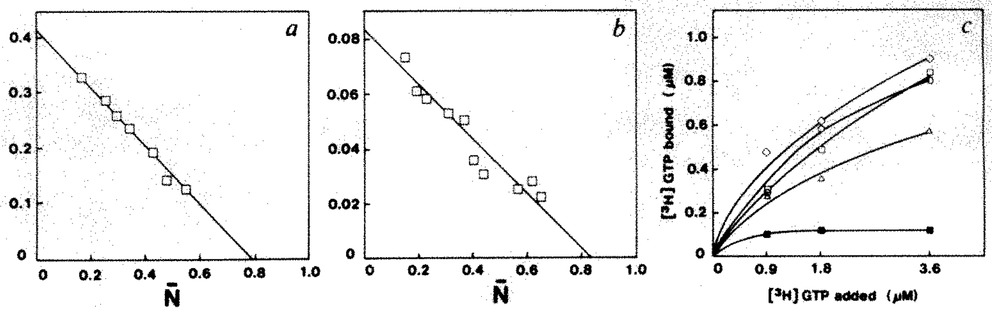

FIG. 3 *a*, *b*, Scatchard plots of GTP (*a*) and GDP (*b*) binding to SELB. $\bar{N}$, Molar concentration of nucleotide bound per mole of SELB. [L], Molar concentration of unbound nucleotide. *c*, Specificity of GTP binding to SELB. A 10-fold excess of unlabelled nucleotide was added to each incubation mixture. □, Without addition; ■, +GTP; ○, +ATP; ◇, +CTP; and △, +UTP.

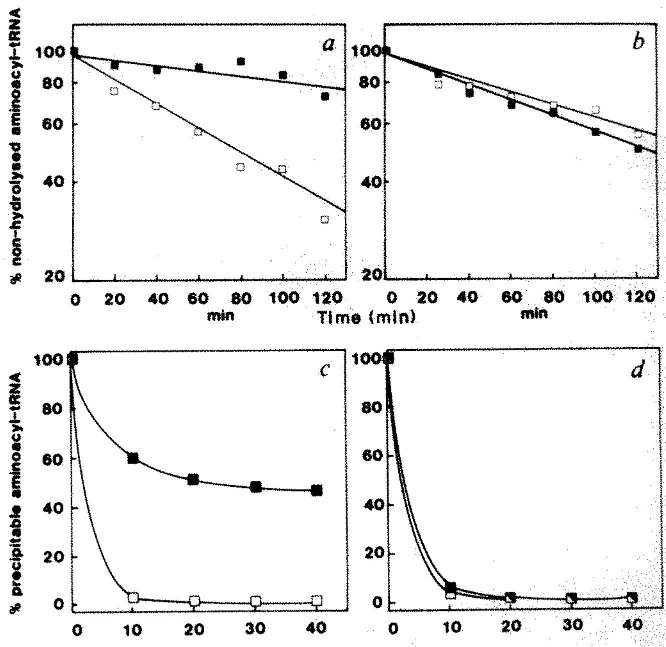
METHODS. Binding was measured by equilibrium dialysis in 200-μl chambers containing 20 mM potassium phosphate, pH 7.0, 5 mM $MgCl_2$, 100 mM KCl, 1 mM DTT, and 1.3 μM (*a*, *c*) or 4 μM SELB (*b*) and 0.3–4.8 μM [^{3}H]GTP or 2–30 μM [^{3}H]GDP, respectively. After a 16-h incubation at 4 °C, three 50-μl aliquots were taken from each vessel, dried on glass fibre filters, applied to rotoszint scintillation cocktail and counted. The same dissociation constants were obtained when the phosphate buffer was replaced by 50 mM Tris-HCl, pH 7.4, 10 mM $MgCl_2$, 100 mM KCl, 1 mM DTT.

FIG. 4 Protection of seryl-tRNA^{UCA} (*a*, *c*) and selenocysteyl-tRNA^{UCA} (*b*, *d*) against alkaline hydrolysis (*a*, *b*) or pancreatic RNase digestion (*c*, *d*) in the presence (■) or absence (□) of SELB. *a*, *b*, Hydrolysis protection experiments[13] were carried out in 200 μl of 50 mM potassium phosphate, pH 7.5, 5 mM $MgCl_2$, 100 mM KCl, 0.1 mM cysteine, containing 0.2 μM tRNA^{UCA} aminoacylated with [^{14}C]serine or [^{75}Se]selenocysteine. The reaction mixtures were incubated at 24 °C in the presence or absence of 1 μM SELB. Aliquots (25 μl) were removed and spotted on glass-fibre filters soaked in ice-cold 10% trichloroacetic acid to precipitate the tRNA. The filters were washed 4 times with 2 ml 5% trichloroacetic acid and once with 2 ml 70% ethanol, dried, and their radioactivity determined. *c*, *d*, RNase protection experiments[15] were performed in 100 μl of 20 mM potassium phosphate, pH 7.2, 5 mM $MgCl_2$, 100 mM KCl, 0.1 mM cysteine, containing 0.2 μM tRNA^{UCA} aminoacylated with either [^{14}C]serine or [^{14}C]selenocysteine and in the presence or absence of SELB. Reaction mixtures were incubated for 5 min at room temperature, then cooled on ice. An aliquot of 20 μl was removed and precipitated on glass fibre filters as described above. Then [illegible] μl pancreatic RNase (2 mg ml^{-1}) was added and 20-μl aliquots were removed after 10, 20, 30 and 40 s and the acid-insoluble radioactivity determined as described above. All experiments were carried out in an anaerobic chamber under N_2–H_2 (96:4) atmosphere.



These results strongly indicate that SELB specifically complexes selenocysteyl-tRNA^{UCA} but does not recognize tRNA^{UCA} aminoacylated with serine. Complex formation is independent of the presence of guanine nucleotides, as is complex formation with *E. coli* IF-2 (ref. 14) or EF-Tu from thermophilic bacteria (M. Sprinzl, personal communication). The basis for this specificity towards selenocysteine remains to be elucidated, but could depend on either the tRNA^{UCA} undergoing a conformational change when serine is converted to selenocysteine, or, more plausibly, the direct recognition by SELB of the selenol group at the aminoacyl residue.

SELB most probably functions biochemically as an alternative elongation factor to EF-Tu, specific for the insertion of selenocysteine directed by the UGA codon in the *fdhF* mRNA. Apart from the sequence homology with EF-Tu and IF-2, several other lines of evidence support this role of SELB. First, SELB binds guanine nucleotides and selenocysteyl-tRNA. Second, EF-Tu exhibits a 200-fold lower affinity for seryl-tRNA^{UCA} than for any other aminoacyl-tRNA involved in elongation (G. Ott and M. Sprinzl, personal communication). Furthermore, conversion of the serine residue to a selenocysteine residue does not change this affinity (G. Ott, K.F. and M. Sprinzl, unpublished results). Thus, under *in vivo* conditions, selenocysteyl-tRNA cannot compete for ternary complex formation with EF-Tu. Finally, lesions in *selB* do not interfere with selenocysteyl-tRNA formation[8]; rather, they promote an accumulation of selenocysteyl-tRNA and, despite the resulting intracellular selenocysteyl-tRNA concentration, there is no incorporation of selenocysteine at the specific UGA codon by EF-Tu.

These findings are therefore consistent with SELB being a new G protein functioning as a translation factor that specifically recognizes the aminoacyl residue of a tRNA. The recognition of the selenocysteyl residue esterified to tRNA^{UCA} thus could be the biochemical basis for the extreme specificity with which the UGA codon in the *fdhF* mRNA directs the insertion of selenocysteine only, and not the insertion of L-serine; this is exemplified in mutants that cannot convert seryl-tRNA^{UCA} into selenocysteyl-tRNA[8]. The higher M_r of SELB (68K) relative to that of EF-Tu (43K) indicates that SELB probably has additional functions. One function of SELB could be to recognize the aminoacyl residue. Other functions could be the specific recognization of the mRNA context around the selenocysteine-specific UGA codon and/or to compete for the binding of release factor-2. □

The conformation of the DNA double helix in the crystal is dependent on its environment

Zippora Shakked, Gali Guerstein-Guzikevich, Miriam Eisenstein, Felix Frolow & Dov Rabinovich

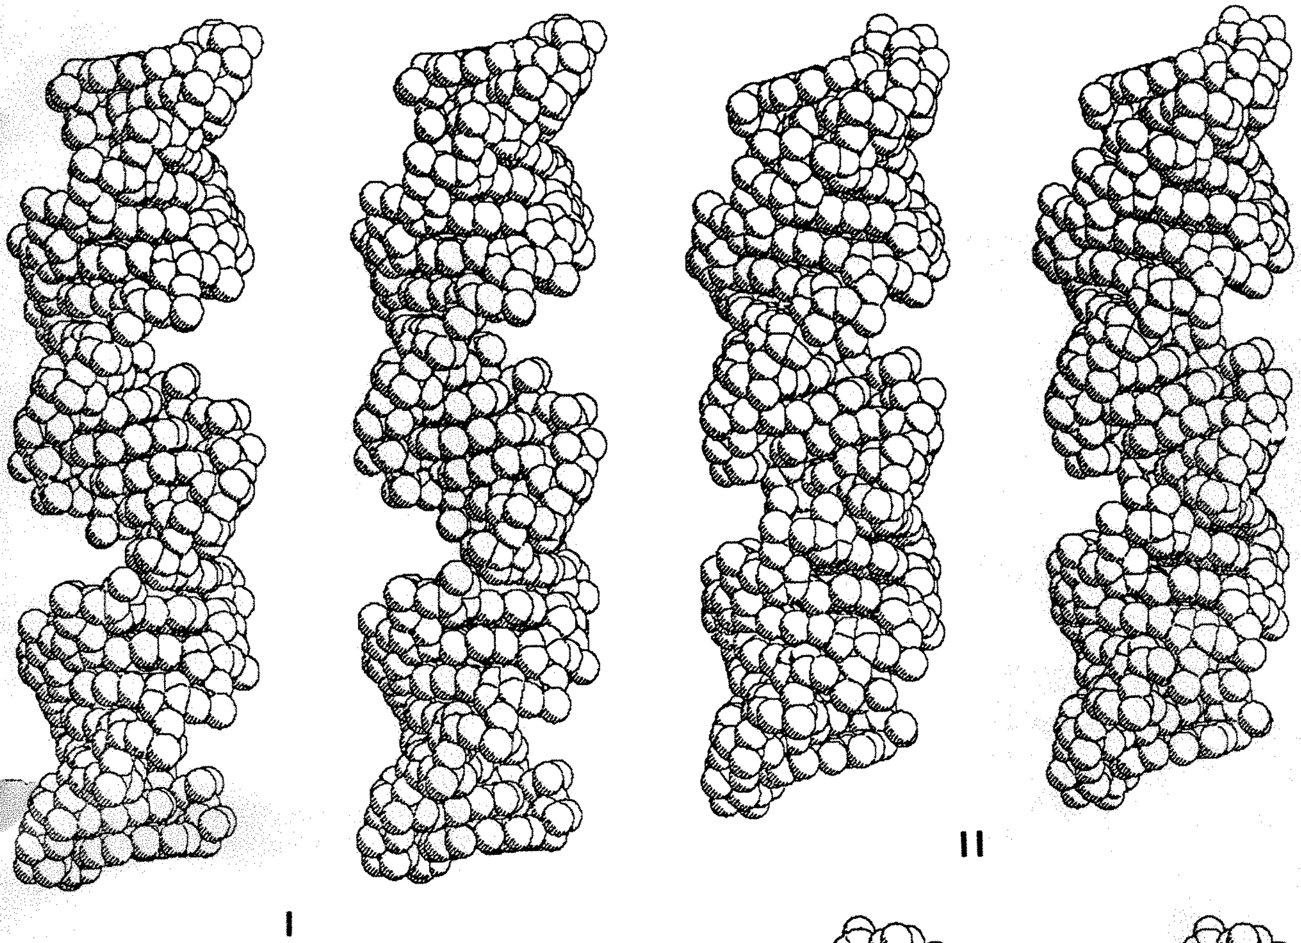
Department of Structural Chemistry, The Weizmann Institute of Science, Rehovot 76100, Israel

STUDIES of the crystal structures of more than 30 synthetic DNA fragments have provided structural information about three basi forms of the double helix: A-, B- and Z-form DNA[1–5]. Thes studies have demonstrated that the DNA double helix adopts highly variable structure which is related to its base sequence. The extent to which such observed structures are influenced by the crystalline environment can be found by studying the same molecule in different crystalline forms. We have recently crystallized one particular oligomer in various crystal forms. Here we report the results of structural analyses of the different crystal structures and demonstrate that the DNA double helix can adopt a range of conformations in the crystalline state depending on hydration, molecular packing and temperature. These results have implications on our understanding of the influence of the environment on DNA structure, and on the modes of DNA recognition by proteins.

The octamer d(G-G-G-C-G-C-C-C) or G-G-G-C-G-C-C-C has been crystallized as an A-DNA double helix in two crystal forms, tetragonal and hexagonal. The structure of each form was determined at room temperature (RT) and low temperature (LT). The experimental details for crystallization, data collection and structure determination are given in Table 1.

The crystal structures of the tetragonal forms have been previously reported[6,7] and their double-helical structures at the two temperatures found to be very similar; therefore, we refer to only the RT structure of the tetragonal form. We found that when hexagonal crystals are cooled, however, there are drastic changes in unit-cell volume and resolution of the data (Table 1). Such changes indicate a phenomenon of phase transition, and therefore the crystalline environment of the hexagonal LT structure is different from that of the RT structure. Some of the global and local parameters of each of the three structures of the same sequence are given in Table 2, and continuous helices based on the three structures displayed in Fig. 1. Each of these three crystal structures corresponds to a distinct conformation of the A-DNA double helix. The tetragonal structure is of conformation I. This is characterized by a very small tilting (inclination) of the base pairs with respect to the overall helix axis, a large rise per base-pair and a widely open major groove. The hexagonal RT structure is of conformation II, with medium values of base tilting and rise. The major groove is narrower and deeper than that of the tetragonal structure. The hexagonal LT structure is of conformation III. This is a slim helix with a narrower and shallower major groove than those of conformations I and II. The tilting of the bases and the rise are similar to those of conformation II.

These data show that the same oligomer can assume more than one conformation in the crystalline state. The three helices are embedded in three distinct crystalline environments. Among the factors that are likely to influence molecular conformation and crystal packing are hydration and temperature. Analysis of the water structure in the three crystals shows that the level and mode of hydration changes considerably from one conformational type to the next. Conformation I is highly hydrated, II is poorly hydrated and III is fairly hydrated. It seems that during the cooling process of the hexagonal crystals their water structure undergoes an important rearrangement which affects both the helical conformation and packing arrangement.



It is reasonable to assume that during the process of crystallization, the double-helical conformation changes continuously depending on water activity, concentration of counter ions and alcohol. When crystal nucleation is initiated at a state of relatively high water activity then the tetragonal form appears, whereas at low-water activity the hexagonal form crystallizes out. This is also consistent with the crystallization experiments (Table 1). Readjustment of the overall helical shape can also occur during crystal formation to optimize intermolecular interactions. An important observation is that all previously determined A-type octamers crystallized in either tetragonal or hexagonal forms[4,5]. Those of the tetragonal space group were shown to adopt a common elongated helical shape similar to conformation I, whereas most of the ones crystallizing in the hexagonal space group were stubby and short helices similar to conformation II.

The modes of intermolecular interactions observed in the two crystal forms have been extensively studied[6,8-11]. All these interactions involve the van der Waals contact of a terminal base pair with the flat minor groove of an adjacent duplex. In some cases the intermolecular contact is further stabilized by hydrogen bonds depending on its location at the minor groove and the particular base sequence. We have not found any substantial evidence to show that the difference in global structure observed in the different crystalline environments is caused by such interactions. But we do not rule out the possibility that water-mediated intermolecular contacts may be important in this respect.

Thus, we argue that either packing requirements control the overall helical shape or a particular conformation crystallizes in the appropriate crystal form. In any event, the important finding is that the observed structure and crystal packing are mutually dependent.

What is the role of the base sequence in determining the conformation of DNA in the crystalline state? Previous studies

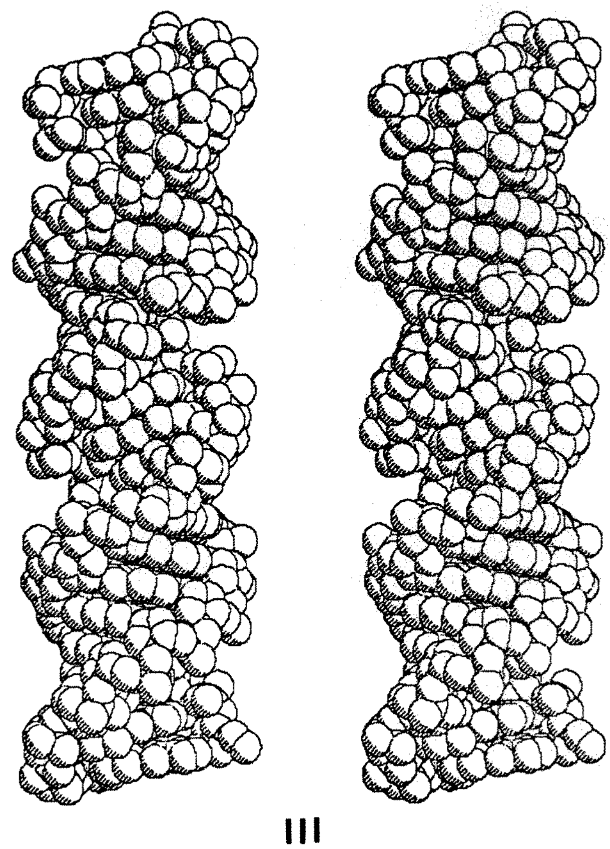


FIG. 1 Stereoscopic space-filling drawings of continuous helices based on conformations I, II and III. Each helix (24 base pairs long) was generated by rotating and translating the corresponding double-helical octamer with respect to the overall helix axis, using the average values of helix twist and rise per base pair of Table 2.

have demonstrated a correlation between the local structure and the base sequence. The effect of the base sequence in A- and B-DNA is shown primarily by variations in base-stacking geometry and, to a much lesser extent, by changes in the sugar-phosphate backbone[4,5]. Variations in the arrangement of the base pairs can be estimated from the relative rotations and translations of adjacent base pairs. The following three of these parameters are largely variable in the crystal structures: (1) the local helix twist, which is the relative rotation of two successive base pairs with respect to the helix axis; (2) the roll angle, a measure of the opening of the base pairs towards the helical grooves; and (3) the slide, which is the relative displacement of the base pairs along their long axes. The values of these parameters for each of the three structures are given in Table 2. Significant changes are observed from one crystal to the other.

The central pyrimidine-purine site of the sequence used in the study described here has been studied in several other A-type octamers: C-C-C-C-G-G-G-G (ref. 9), G-G-C-C-G-G-C-C (ref. 10, 11), and G-C-C-C-G-G-G-C (ref. 12). In all these structures as well as the tetragonal form of G-G-G-C-G-C-C-C (conformation I), the C-G step adopts a unique stacking geometry with a small twist (average 24°) and large negative slide (average −2 Å). The roll angles of the C-G doublets display a wide range of values (0–12°). The sugar-phosphate backbone of each of the C-G sites adopts an extended structure in contrast to the usual folded conformation observed in all other sites.

Only one of the three common properties is retained in the C-G step of conformation II, namely the helix twist (24°). The amount of slide is smaller (−1.3 Å). The values of the two parameters in conformation III (29° and −1.0 Å) differ much more from those of conformation I. The central backbones of conformations II and III have the usual folded structure. The stacking geometries of the C-G doublets in conformations I, II and III are shown in Fig. 2. The change in sliding motion is reflected by the amount of overlapping between the centr guanine bases. The overlapping diminishes gradually going from conformation I by way of II to III. The decrease in interstrand stacking between the guanines is associated with a simultaneous increase in intrastrand stacking between the guanine and cytosine bases.

The various parameters of several other helical steps also differ significantly between the different crystals. We believe that such local variations are not induced directly by crystal-packing forces for the following reasons. As mentioned before, the intermolecular interactions in all crystal forms are relatively soft and non-specific. Moreover, the 2-fold symmetry is largely retained in the duplexes that do not incorporate crystallographic symmetry axes[1,4]. Even in cases where intermolecular interactions deform asymmetrically the double helix as for the B-dodecamer series[2], the local structure of equivalent base pairs is similar.

We suggest that changes in local structure of the same molecule in different crystalline environments are induced by hydration effects. This is supported by a common water structure observed in all C-G sites displaying the specific geometry described above (Fig. 3), in which a string of water molecules runs across the minor groove and interacts directly with the two guanines and two 3′-phosphate groups. This water structure is further stabilized by four water branches which are hydrogen-bonded to the sugar-phosphate backbone of two nearby symmetry-related duplexes. Any sliding of the base pairs in a direction that reduces the overlap of the guanines would disrupt this

TABLE 1 X-ray data of d(G-G-G-C-G-C-C-C)

No. of ordered waters per duplex*	88	45	96

The deoxyoligonucleotide was prepared by the solid-phase procedure using fast phosphoramidite chemistry[15], and purified by ion-exchange and HPLC. Crystallization was done at 19 °C using solutions containing 2 mM DNA, 5 mM $MgCl_2$, 0.15 mM spermine–HCl, 5% 2-methyl-2,4-pentanediol (MPD) and 50 mM sodium cacodylate (pH 7.0), equilibrated against reservoirs of concentrated MPD solutions (30 or 50%). Tetragonal crystals appeared predominantly at 30% MPD whereas hexagonal crystals appeared at 50% MPD when the drops almost dried out. The hexagonal crystals could be preserved only by adding buffered solutions containing 75% MPD. Diffraction data were measured at both RT and LT on a Rigaku AFC5 diffractometer equipped with a rotating anode source. For the RT experiment the crystal was sealed in a glass capillary containing a droplet of mother liquor. For the LT experiment a naked crystal was mounted directly and shock-cooled to 100 K (ref. 16). The structures were solved by the multi-dimensional search method ULTIMA[17] and refined using the restrained least-squares program by Hendrickson and Konnert[18]. Solvent peaks located from electron density maps and satisfying hydrogen-bonding criterions were included in the refinement as oxygen atoms.

* Although the total number of ordered waters included in the refinement of conformation I was smaller than that of conformation III, the number of waters located at the first and second hydration shells of conformation I was 20 more than that for conformation III.

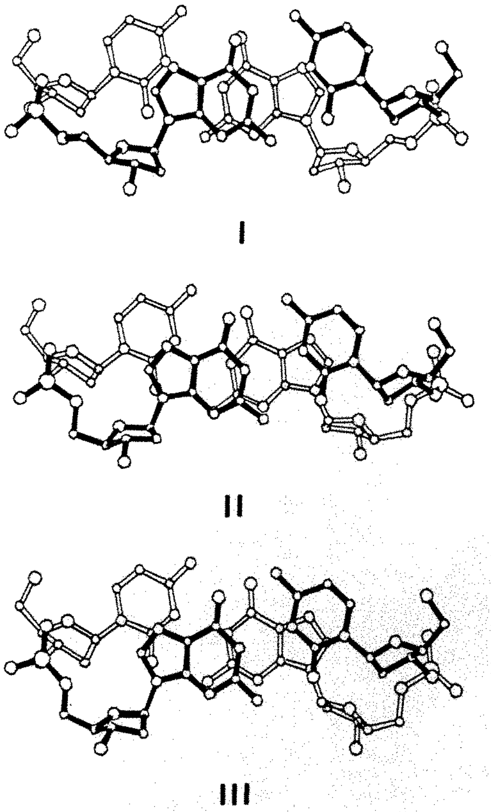

FIG. 2 Stacking geometry of C-G doublets in conformations I, II and III. The view is perpendicular to the upper base pair. It shows the decrease in slide from conformation I by way of II to III, and the increase in helix twist from conformations I and II to III.

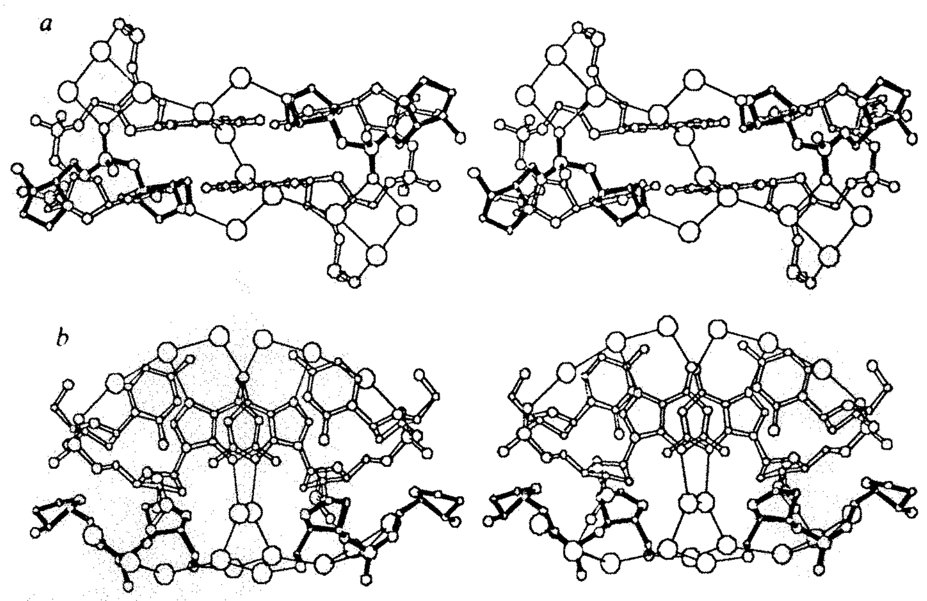

FIG. 3 Stereoscopic drawings of hydration of the C-G doublet in conformation I. *a*, The view is down the minor groove showing the interactions of water molecules with N3 atoms of guanines and the adjacent 3′-phosphate oxygens. The water structure is stabilized by hydrogen bonds to the sugar-phosphate backbone of G1 and G2 from neighbouring duplexes (dark bonds). *b*, The view is perpendicular to the upper base pair, showing the hydration at both grooves. At the major groove a string of waters is hydrogen bonded to O6, N7 and 5′-phosphate oxygen atoms of each of the guanine residues.

Hydration. At the major groove, strings of water molecules interact with the guanine bases and the 5′-phosphate oxygens of the locally extended backbone. Hence, the unique local structure observed in all the tetragonal C-G sites is stabilized by this water structure. An equivalent type of hydration cannot be accommodated in the hexagonal crystals because part of the central region of the minor groove is blocked by a neighbouring molecule, thus demonstrating the indirect influence of crystal packing on local DNA structure.

TABLE 2 Helix parameters

Structure	Global parameters I	II	III
Helix twist (°)	32 (4)	31 (5)	32 (2)
Rise per base-pair (Å)	3.3 (0.1)	2.9 (0.3)	2.9 (0.3)

G-C	34.7	37.3	32.0	3.7	3.5	6.1	−1.3	−2.0	−0.8
C-C	31.2	29.9	33.4	6.4	10.3	7.5	−1.7	−2.4	−1.7
C-C	32.3	30.0	30.8	7.2	11.1	6.9	−1.4	−1.5	−1.5
Average	31.5	30.6	32.3	5.4	7.2	6.7	−1.6	−1.9	−1.2
s.d.	3.6	4.5	2.2	1.7	4.9	1.9	0.3	0.4	0.6

The numbering of residues from 5′ to 3′ is G1 to C8 in the first strand and G9 to C16 in the second. Hence, the first G-G step consists of base pairs G1·C16 and G2·C15, and so on. Helix diameter was calculated from the average distance of phosphorus atoms to the overall helix axis. The groove widths were estimated from averaging the shortest P–P distances across each groove of the continuous helix. Definitions of the other parameters are given in refs 2 and 19. The convention of signs used here is the one agreed on at an EMBO workshop on DNA curvature and bending[20]. Hence, propeller twist, base-pair displacement and slide are negative unlike those of previous publications. The s.d. (given in parentheses) is the r.m.s. deviation from the mean. I, Tetragonal conformation; II, hexagonal RT conformation; III, hexagonal LT conformation.

The results presented here have implications on the modes of DNA recognition by proteins[13,14]. The specificity of the recognition of a sequence of bases and hence the stability of the DNA-protein interface are dependent on the correct alignment of the base pairs along the helix. We show that a specific alignment of two successive base pairs is driven by a local hydration. It is therefore reasonable to anticipate that even larger changes in the orientation and position of the DNA base pairs can be accomplished by direct or water-mediated interactions with the protein. Also, specific hydration of the base pairs at one groove may govern the degree of helical twist, roll and slide needed to accommodate protein–DNA contacts at the other groove.

From the results of this study we conclude that the DNA double helix can adopt a range of conformations in the crystalline state depending on hydration, molecular packing and temperature. Such studies demonstrate the capability of DNA to undergo important conformational changes as a result of modest variations in its environment. □

Note added in proof. Two conformations in the crystal were recently reported for another A-DNA octamer[21].

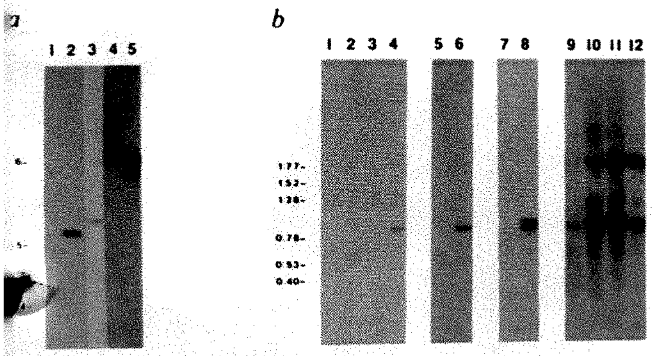
ion of a functioning cutinase gene, we inserted this gene from F. *solani pisi* into *Mycosphaerella* spp. by a transformation procedure using whole fungal cells and lithium acetate treatment[4,8]. The plasmid pU5-11 contains the cutinase structural gene and nearly 4 kilobases (kb) of 5′ upstream sequence, plus kb of 3′ non-coding DNA[4]. *Mycosphaerella* was cotransformed with this plasmid and a plasmid containing the hygromycin-resistance gene[4,9,10]; the transformants were selected for hygromycin resistance and screened for the cutinase gene by Southern blot analysis (Fig. 1). The four transformants shown in Fig. 1 were cut with *Sty*I, an enzyme that does not cut within pU5-11. The integration events seem to be random. The transformants M-25 and M-101 (lanes 4 and 5) probably contain tandem duplications. Because signals of high molecular weight were present, it is likely that M-101 also has another separate site of integration.

We grew the transformants under inducing conditions[11] to ee whether the cutinase gene that is induced by cutin monomers in *F. solani pisi*[12] is transcriptionally regulated in the *Mycosphaerella* transformants as well. Northern blots of transcripts rom wild type and the four *Mycosphaerella* transformants were hybridized with radioactively labelled cutinase cDNA from *Fusarium* as probe (Fig. 1). An interval of 48 hours was chosen because in that time the level of transcription of the gene in *Fusarium solani pisi* reaches a maximum[13]. There was no hybridization with the wild-type *Mycosphaerella* RNA (lanes 1 and 2), showing that transcripts from this organism share no homology with *Fusarium* cutinase messenger RNA. Transformants M-12 (lane 4) and M-21 (lane 6) displayed similar patterns, with a unique transcript comparable in size to authentic *Fusarium* cutinase mRNA. Transformants M-25 and M-101 gave wo and three separate transcripts, respectively. These multiple transcripts might have been due to differential processing or splicing of the mRNA; alternatively, insertion in different positions could lead to the production of transcripts of different sizes in *Mycosphaerella*. A time course of induction of cutinase gene in transformant M-101 (Fig. 1, lanes 8-12) showed a low level of constitutive expression of the gene and maximal expression at 48 h after the addition of the inducer.

To investigate whether the transformants that produced transcripts containing the coding sequence for cutinase were translated, the culture supernatants from the induced cultures were subjected to western blot analysis, using as probe antibodies raised against *Fusarium solani pisi* cutinase. There was no cutinase detectable from the wild type even after 72 h of induction (Fig. 2). All four transformants produced cutinase within 72 h of addition of cutin hydrolysate. Within 24 h of adding inducer, the transformant M-101 was producing cutinase, which increased up to 72 h; For transformant M-25, cutinase levels were fairly high by 72 h, reaching 74% of the M-101 cutinase levels, although the induction was slower (data not shown). Transformants M-21 and M-12 yielded much less cutinase and this could only be found 72 h after the addition of the inducer.

Next we tested the proteins that were generated by the transformants and which cross-reacted with antibodies against *Fusarium* cutinase to see whether they showed enzyme activity. Cutinase activity correlated with the levels of the proteins detected by immunoblot analyses (Fig. 2): transformant M-101 gave the highest cutinase activity, followed by M-25, whereas supernatants from M-21 and M-12 were much less active. Thus, the levels of transcription, translation product and cutinase activity from the transformants were all in agreement.

We used a papaya fruit bioassay[5] to investigate the pathogenicity of *Mycosphaerella* transformants expressing the inducible cutinase gene. Both wild-type *Mycosphaerella* and the transfor-



IG. 1 *a*, Southern blot analysis of genomic DNA from wild-type *Mycosphaerella* spp. and transformants. Lane 1, wild type; lanes 2, 3, 4 and 5 epresent transformants M-12, M-21, M-25 and M-101, respectively. Co-transformation was as described[4], with 10 μg of each plasmid yielding 2–4 stable transformants per μg; about half of these showed mitotic stability and were analysed by Southern blotting. Genomic DNA from these transformants was digested with *Sty*I, electrophoresed in 0.7% agarose, transferred to nitrocellulose and probed with nick-translated ^{32}P-labelled cDNA for cutinase from *F. solani pisi*[3]. Sizes in kilobases and migration of lambda *Hind*III–*Eco*RI fragments are shown on the left. *b*, Northern blots showing induced cutinase transcript levels in the transformants of *Mycosphaerella* spp. Lanes 1 and 2, wild-type *Mycosphaerella* uninduced and induced for 48 h respectively; lanes 3 and 4, 5 and 6, 7 and 8 represent transformants M-12, M-21, M-25 respectively: in each case the odd number is uninduced and the even number is induced for 48 h; lanes 9, 10, 11, and 12 represent transformant M-101 induced for 0, 24, 48 and 72 h, respectively. In each case glucose-grown fungi were induced with cutin hydrolysate (10 mg ml^{-1}) and RNA isolated with guanidium hydrochloride[16] was separated on 1% formaldehyde agarose gels, transferred to nylon and hybridized to ^{32}P-labelled cutinase cDNA, as described in the legend to Fig. 1*a*. The total RNA levels loaded in each lane did not vary, as we confirmed by washing off the cutinase probe and reprobing the blot with ^{32}P-labelled actin cDNA.

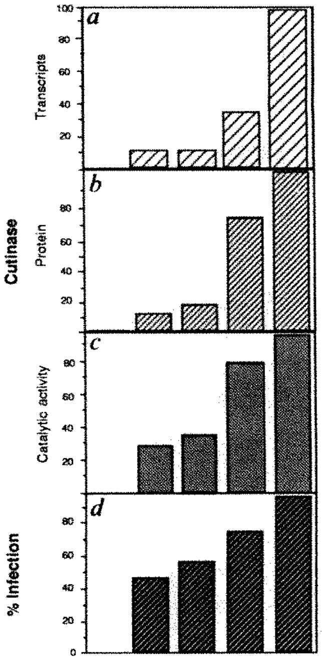


FIG. 2 Correlation of levels of cutinase transcripts (*a*), protein (*b*), enzymatic activity (*c*), with infectivity (*d*) of transformants of *Mycosphaerella* spp. The level of cutinase transcripts was measured by scanning the autoradiograph of the northern blot corresponding to a 48-hour period of induction, as described in the legend of Fig. 1*b*; the levels of cutinase protein produced were measured by scanning the western blot of culture supernatants from 72 h-induced cultures; the levels of enzymatic activity of cutinase in the culture supernatants were determined using *p*-nitrophenylbutyrate as the substrate[11] after 72 h induction; the per cent infection of the wild type and the transformants on intact papaya fruit was measured as described[5]. In all cases, data were normalized against values for transformant M-101 taken as 100. The cutinase activity and per cent infection for M-101 were 43.7 nmol min^{-1} ml^{-1} and 90%, respectively.

mants cause lesions when inoculated on wounds (data not shown). The wild type did not cause lesions when inoculated on intact fruits without wounds (Fig. 3), but the transformants expressing the *Fusarium* cutinase gene did. Frequency and size of lesions were the largest for transformant M-101; nearly all locations inoculated were infected. In fact, the incidence of infection and the severity of the lesions caused by this transformant were essentially identical to those observed with *Colletotrichum gloeosporioides*, an authentic pathogen of intact papaya fruits[5]. The extent to which the transformants become parasites on papaya fruit therefore correlates extremely well with the expression of *Fusarium* cutinase gene (Fig. 2).

To test whether infection of intact fruits by the transformant was due to cutinase, rabbit antibodies against the cutinase from *F. solani pisi* were included with the spore suspension of the M-101 transformant, which produced the most cutinase and the most severe lesion. This antibody preparation, which inhibits *Fusarium* cutinase, prevented lesion formation by transformant M-101 (Fig. 3). Thus, it is clear that *Fusarium* cutinase activity produced by the *Mycosphaerella* transformant enabled it to penetrate the intact fruit and infect it.

We have shown that by inserting a gene encoding a cuticle-degrading enzyme from a pathogenic organism into one that infects only through wounds, the latter can now infect intact plant organs without a wound. As *Mycosphaerella* spp. is able to infect wounded tissue, then this fungus must have most of the genetic machinery required for parasitism. Apparently, however, it cannot penetrate the host's first line of physical defence, the cuticle. Overcoming this limitation by gene insertion allows this organism to infect intact papaya fruits.

Regulation of the *Fusarium* cutinase gene is unchanged when inserted into *Mycosphaerella*: on contact of the spore with the plant surface, gene expression is triggered by cutin monomers released by the small amount of cutinase carried by the spore. The transformants that efficiently expressed cutinase showed low levels of constitutive expression (Fig. 1, lane 9; als confirmed by Western blot analysis, data not shown). The resulting level of cutinase would release monomers from papaya cuti Dihydroxyhexadecanoic acid is a most effective inducer of t cutinase gene in *Fusarium*[7,12] and is the most abundant monom of papaya cutin[14], so the appropriate inducer is available to th transformants when placed on the fruit surface, enabling the to use their regulated expression of cutinase to gain entry int the fruits and infect them. Activation of the cutinase gene i isolated nuclei from *F. solani pisi* by the unique cutin monome has been demonstrated[12]. This selective initiation of transcription of the cutinase gene required a protein factor from th *Fusarium* extract. Apparently *Mycosphaerella* spp. possesses thi protein or a functional analogue, as it can use cutin hydrolysat to activate the *Fusarium* cutinase gene in a similar way. This i not surprising, as similar target proteins that regulate transcription are present in many eukaryotes[15]. By understanding th regulation of genes essential for pathogenesis, it might b possible to interfere with their expression and hence pathogenesis. □

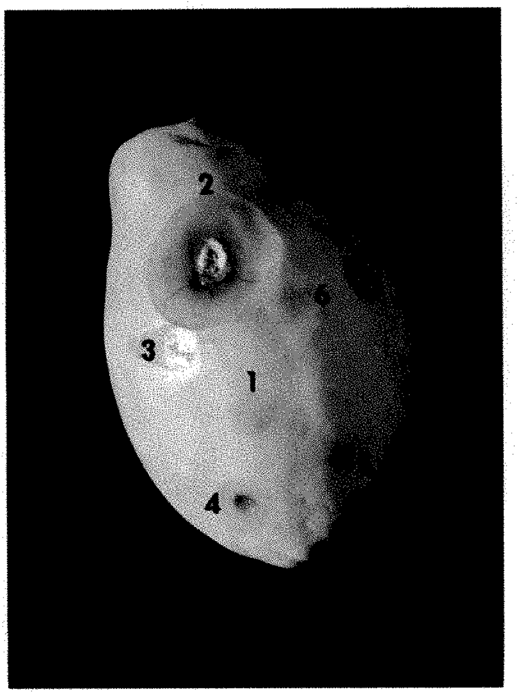

FIG. 3 Lesion formation on intact papaya fruits by *Mycosphaerella* transformants into which *Fusarium* cutinase gene was introduced. (1) Wild type *Mycosphaerella* spp.; (2) transformant M-101; (3-5) transformants M-12, M-25 and M-21, respectively; (6) transformant M-101 with rabbit antibodies prepared against *Fusarium* cutinase. The picture was taken 72 h after keeping the intact papaya fruits with the spore suspension (5×10^4 spores in 50 μl) on it at 26°C in a 100% humid chamber as before[5].

PLASMA high density lipoproteins (HDL) are a negative risk factor for atherosclerosis. Increased HDL is sometimes clustered in families, but a genetic basis has never been clearly documented[1]. The plasma cholesteryl ester transfer protein (CETP) catalyses the transfer of cholesteryl ester from HDL to other lipoproteins and therefore might influence HDL levels[2]. Using monoclonal antibodies, we show that CETP is absent in two Japanese siblings who have markedly increased and enlarged HDL. Furthermore,

---

§ To whom correspondence should be addressed.

They are homozygous for a point mutation in the 5′-splice donor site of intron 14 of the gene for CETP, a change that is incompatible with normal splicing of pre-messenger RNA[3]. The results indicate that the family has an inherited deficiency of CETP due to a gene splicing defect, and illustrate the key role that CETP has in human HDL metabolism.

A Japanese subject has recently been described with markedly increased HDL and low levels of cholesteryl ester transfer activity[4]. Low activity could reflect a deficiency of CETP, the presence of an inhibitor[5], or a substrate effect (high HDL)[6]. Our goals were to assess blood and plasma samples from the Japanese subject and his family for the presence of the CETP of relative molecular mass (M_r) 74,000 (74K)[7], using two different CETP monoclonal antibodies[8,9], and also to analyse the defect at the DNA level using the sequence of the wild-type CETP gene (L.B.A. *et al.*, manuscript in preparation).

CETP in plasma was immunoaffinity-purified using an anti-CETP monoclonal IgG (TP2) column[8] and the retained fraction was analysed by western immunoblotting of SDS-polyacrylamide gels (Fig. 1). In the control subjects, in T.Y. (proband's spouse) and in the four children (Y.Y., K.C., M.D., K.Y.), CETP ran at its characteristic position[7]. Remarkably, CETP was not detected in the plasma of the proband (S.Y.) or of his sister (K.H.) (Fig. 1), even when 300 μl of S.Y. plasma was analysed (S.Y.×3) (Fig. 1). Also, when equal amounts of control and S.Y. plasma were mixed, there was no diminution of the CETP signal following immunoaffinity chromatography (Fig. 1; con+S.Y.).

To quantitate CETP more precisely, plasma samples were analysed by radioimmunoassay using ^{125}I-labelled TP2. In this competitive displacement assay[10], the plasma of S.Y. and K.H. did not displace the standard CETP from the solid phase, which is consistent with no CETP being present (Table 1). The amount of plasma CETP from the children ranged from 38 to 56% (mean 49%) of their mother's value (Table 1), which is consistent with their being obligate heterozygotes for inherited CETP deficiency, with codominant expression determining CETP levels.

In a further attempt to detect CETP in the S.Y. plasma, it was electrophoresed in native polyacrylamide gradient gels and either stained with Sudan Black to show the lipoproteins (Fig. 2a) or transferred onto nitrocellulose and probed with a monoclonal antibody that recognizes a different epitope, ^{125}I-labelled TP6 (Fig. 2*b*). In the lipid-stained preparations, normal HDL appears as a set of diffusely stained bands corresponding to particles of diameter between 8 to 12 nm (Fig. 2*a*; controls 1-4), and low-density lipoproteins (LDL) run as an intense band near the top of the gel. The proband (S.Y.) shows markedly increased and enlarged HDL, extending into the size region of LDL (Fig. 2*a*). Similar results were obtained with his sister (K.H.) (data not shown). Two of the children (K.C. and Y.Y.) showed a distinct increase in staining of the larger HDL subclass, and all showed an increase in HDL-2 (10-12 nm) relative to the smaller HDL-3 (8-10 nm). Thus, the HDL_2/HDL_3 ratio was above normal in the children (Table 1).

Western immunoblot analysis of plasma run on native polyacrylamide gradient gels and probed directly with ^{125}I-labelled TP6, showed that the CETP was present in a diffuse band co-migrating with HDL-3, with a similar distribution in control samples and in samples from T.Y. and the four children (Fig. 2*b*). But, no CETP could be detected in the plasma of either

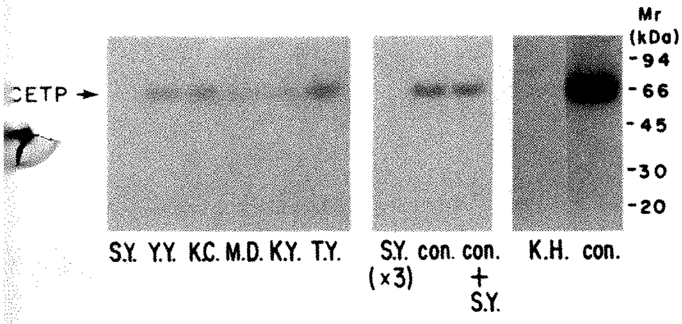

FIG. 1 Western immunoblot analysis of the anti-CETP immunoaffinity-retained fraction of plasma. Results are shown for the proband (S.Y.), his spouse (T.Y.), their four children (Y.Y., K.C., M.D., K.Y.), normolipidemic control subjects (con) and also for S.Y.'s sister (K.H.). The 'S.Y. (×3)' incubation contained 300 μl S.Y. plasma and the 'con+S.Y.' incubation consisted of 100 μl each of control and S.Y. plasma; all other incubations contained 100 μl plasma from the subject indicated. Autoradiographs (3-day exposure, except for K.H. and control, which is a 6-day exposure) of these blots are shown. The position of the 74K CETP is indicated as well as the positions of marker proteins (Pharmacia).

METHODS. Plasma samples containing 1 mM PMSF were subjected to immunoaffinity chromatography on an anti-CETP monoclonal IgG(TP2) column as previously described[8]. Recovery of CETP in the retained fraction under these conditions was ~80%. For western immunoblots, the retained fractions were subjected to SDS-PAGE, transferred to nitrocellulose and incubated with ^{125}I-labelled (Iodobeads-Pierce) anti-CETP monoclonal antibody TP2 (5×10^6 c.p.m./per ml).

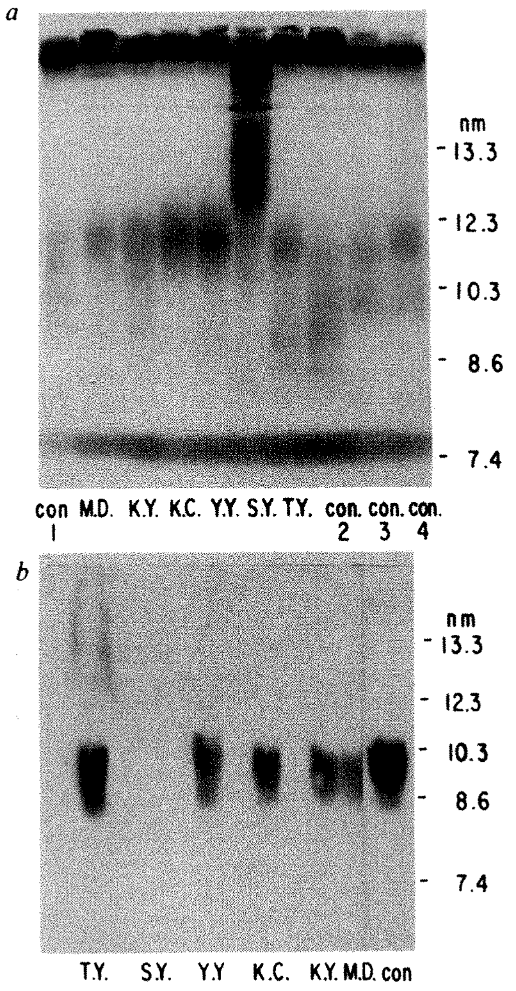

FIG. 2 Native, gradient polyacrylamide gel *a*, stained for lipid with Sudan Black, or *b*, western immunoblotted using anti-CETP monoclonal antibody TP6. *a*, The lipoprotein profile of the S.Y. family (see legend to Fig. 1) and 4 different normolipidemic controls was visualized by Sudan Black staining of a 4-30% gradient acrylamide gel (Pharmacia). Each lane represents 30 μl plasma electrophoresed for 18 h in Tris-borate buffer, pH 8. *b*, Western immunoblot analysis of 30 μl plasma from S.Y. and other family members after reaction with ^{125}I-labelled anti-CETP monoclonal antibody TP6. The hydrodynamic diameters (in nm) were estimated from the mobility of Pharmacia protein standards, which are shown on the right.

S.Y. (Fig. 2*b*) or his sister (data not shown). Thus, analysis of plasma with two different antibodies against CETP (TP2 and TP6) (ref. 9) indicated an absence of CETP in both S.Y. and K.H.

This unusual lipoprotein phenotype raised the question of whether CETP deficiency was a secondary phenomenon or the result of an inherited defect of the gene for CETP. Preliminary Southern blot analysis using the CETP complementary DNA[11], revealed no major insertions or deletions of the CETP gene in the proband (results not shown). Therefore, the proband's genomic DNA (S.Y.) was used as a substrate for amplification of the 16 exons and exon/intron junctions of the CETP gene by the polymerase chain reaction (PCR)[12], in which we used intronic oligonucleotide primers positioned 50 to 100 nucleotides from the junctions. The amplified products were subcloned and sequenced[13]. The sequenced exons and exon/intron junctions encompassing the entire CETP gene (including the polyadenylation region and the translation initiation codon) were conserved when compared with the wild-type sequences (L.B.A. *et al.*, manuscript in preparation), with one exception. At the 5′ splice donor of intron 14 (position + 1) there was a G → A change altering the strictly conserved G-T intron splice donor[14] to A-T. This change was identified in three different subclones derived from separate PCR amplifications of the proband's DNA.

The G → A mutation was confirmed and familial inheritance documented by direct sequencing of amplified DNA from all available family members (Fig. 3). The amplified exon 13,14 PCR product was directly sequenced using a primer originating within exon 14. Figure 3 shows the DNA sequencing ladder in the region of the exon 14/intron 14 junction. Columns 1 and 2 represent the homozygous CETP-deficient individuals (K.H. and S.Y.) and the arrow indicates the A at the first position (+1) of intron 14. Columns 3, 4, 5 and 6 represent the children of the proband and they are heterozygotes with both an A and a G at this position of the sequencing ladder. The mother (T.Y.) of the heterozygotes is represented under column 7 with the normal G at this site. The first nucleotide of a normal intron is never an A (ref. 15). Mutations of the strictly conserved G at this position prevent normal splicing[16]. The position +1 G is critical for correct splicing as it is involved in binding U1 small nuclear ribonucleoprotein particles (U1 snRNPs) and is the residue that undergoes cleavage in the spliceosome and lariat formation[17]. A similar G → A mutation in the conserved splice donor site in intron 1 or intron 2 results in two forms of β-thalassemia. Both forms have abnormal β-globin mRNA and no β-globin protein[18,19]. In some cases, splice site mutations lead to activation of nearby cryptic splice sites[20] or use of an alternative normal splice site (exon skipping)[21], resulting in a truncated transcript and/or abnormal protein. The epitope of TP2 is at the C-terminus of CETP[9], corresponding to a region of the CETP gene downstream of the mutation. But CETP is also undetectable with the TP6 antibody (Fig. 2*b*), whose epitope maps between amino acids 261 to 367 of CETP[9]. This region of CETP is encoded by exons proximal to the site of the mutation. Thus, even if an alternative splice site is used in the mutant CETP gene, no CETP polypeptide is found in plasma. Th dinucleotide ^{m}CpG is under-represented[22] in the genome, but contributes to most (>35%) mutations characterized by single-base changes[23]. We speculate that the CETP deficiency of S.Y. and K.H. might have involved a hot-spot deamination on the non-coding strand.

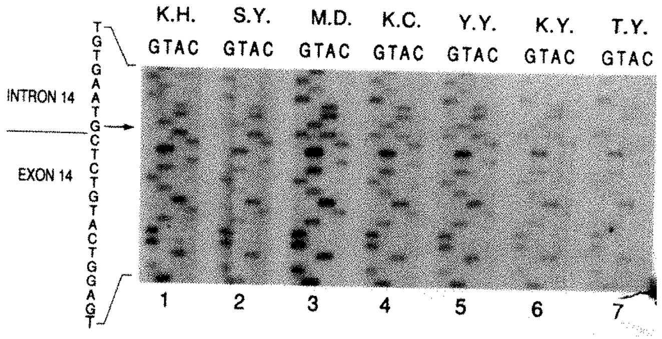

FIG. 3 DNA sequence ladder generated from the amplified products at the exon 14/intron 14 junction of the CETP gene in a family with CETP deficiency. Columns 1 and 2 (K.H. and S.Y.) of the autoradiograph (96 h exposure) represent the sequence of the homozygous CETP-deficient individuals. The arrow indicates the A residue observed in both K.H. and S.Y. Columns 3, 4, 5 and 6 (M.D., K.C., Y.Y. and K.Y.) show the heterozygotes with both an A and a G at position +1 of the intron. Column 7 (T.Y.) shows the sequence of the mother's DNA.

METHODS. Genomic DNA was isolated[24] from 10 ml blood and used as a substrate for amplification by PCR[12]. Polymerase chain reactions were carried out in a total volume of 100 μl under mineral oil, and contained 3 μg genomic DNA, 100 pmol primer A (5′-CCTGAGCTATGAGACAAAAG-3′, located 92 nucleotides 5′ of exon 13 of the gene for CETP), 100 pmol primer B (5′-AAAAGGTGAAATGGGAAGCT-3′ located 43 nucleotides 3′ of exon 14 of the gene for CETP), 2.5 U *Taq* polymerase (Cetus), 200 μM each dNTP, 10 mM Tris-HCl, pH 8.3, 50 mM KCl, 1.5 mM $MgCl_2$, 0.01% gelatin. The amplified products (30 cycles at 94°C for 0.5 min, 55°C for 1 min, 74°C for 3 min) were purified by Centricon-30 (Amicon) filtration and sequenced with a ^{32}P-labelled exon 14 primer (5′-CCAGAGCTTCCTGCAGTCAA-3′ located 56 nucleotides 5′ of the exon 14/intron 14 boundary) according to the Higuchi modifications of the 'Sequenase' USB protocol[25]. The sequencing reactions were heat-denatured and resolved on a 6% polyacrylamide gel containing 7 M urea[26].

NEW Books from Macmillan

New Concepts in Cancer

Metastasis, Oncogenes and Growth Factors

Edited by Chantal Etievant, Centre De Recherche Pierre Fabre, Castres, France, Jean Cros, CNRS, Toulouse, France and Youcef M Rustum, Roswell Park Memorial Hospital, Buffalo, USA

This book defines and reviews the clinical status of metastatic disease and the present status of response to radiation and chemotherapy, identifies factors associated with and/or responsible for tumor metastasis and evaluates the role of various growth factors in metastasis and therapy It also considers the possible relationship between the overexpression of oncogenes and clinical resistance to chemotherapy and possible therapeutic strategies arising from this relationship, if proven

Contents · New Therapeutic Approaches in Recurrent Metastatic Disease, *M Boiron* / Features of Tumor Progression in RasH Transformed Rat Embryo Cells, *R.J Muschel et al* / Organ Specificity of Metastasis Adhesive, Invasive and Growth Properties of Organ-Specific Metastatic Cells, *G.L.Nicholson* / Role of 12-Lipoxygenase Metabolites and Integrin Glycoprotein Receptors in Metastasis, *K.V Honn et al* / The Rapid Destruction of Cancer Cells in the Microvasculature, *L Weiss* / The Control of Cell Movement byLaminin and its Role in Metastasis; *J C.Lissitzky et al* / Dormant Metastatic Cells Hypotheses on Mechanisms, Magnitude, Failure and Control, *L Israel* / Estrogen-induced Pro-cathepsin and its Relationship to Breast Cancer Invasion and Metastasis, *H.Rochefort et al* / The Selection for Metastatic Cells by Drug Resistance Implications for Tumoral Progression, *M-F Poupon et al* / Calcium Channel Blockers and Cisplatin: Synergistic Antimetastatis Effects; *J M Onoda et al* / In Vitro and In Vivo Assays for Invasion and Metastasis Application to Drug Testing, *M M Mareel et al* / The Structure and Function of Growth Factor Receptors and Their Subversion to Cancer, *G Panayotou et al* / Cell Growth Signalling in Fibroblasts· The Role of G-Proteins; *J Pouyssigur et al* / The Bombesin Receptor Complex and Cell Growth Physiology and Pathology; *G.Gaudino et al* / Hormonal Effects on Gastrointestinal Growth, *C P Townsend et al* / Regulation of Fibroblastic and Epithelial Cell Function by Transforming Growth Factors; *H.L Moses et al* / The Role of Autocrine Lymphokines in Epstein-Barr Virus Associated Malignancies; *T.Tursz* / The Role of Hematopoeietic Growth Factors, *P Mannoni* / Index

New Concepts in Depression

Edited by M Briley, Pierre Fabre Medicament, Castres, France and G Fillion, Head of Neuroimmunoendocrinology, Pasteur Institute, Paris

Depression is increasingly seen as an important debilitating neurological condition This book brings together a timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression In addition, a number of chapters concentrate on clinical or physiological phenomena associated with depression The general attitude of the book is one of openness to new ideas several of which are presented here for the first time.

Im Fachbereich Medizin der Johannes Guttenberg-Universitat Mainz ist am Institut fur Toxikologie ab sofort eine

Professor auf Lebenszeit für Angewandte Toxikologie

(Bes.Gr. C 3 BBesG)

wieder zu besetzen

Der/Die Stelleninhaber/in muß also Leiter der Abteilung fur Angewandte Toxikologie das Fach Toxikologie und Pharmakologie in Forschung und Lehre angemessen vertreten Ferner soll er/sie zu humantoxilologischen Problemen Stellung beziehen konnen Bevorzugt werden Bewerber/innen aus dem Gabiet der Medizin oder der Naturwissenschaften mit speziellen Erfahrungen in toxikologischer Forschung zellbiologischer, molekularbiologischer oder biochemischer Richtung Er/Sie muß fur das Fach Toxikologie habilitiert sein oder eine gleichwertige Qualifikation besitzen

Schwerbehinderte werden bei entsprechender Eignung bevorzugt eingestellt

Bewerbungen sind in deutscher Sprache mit den ublichen Unterlagen bis 4 Wochen nach Erscheinen dieser Anzeige zu richten and den Dekan des Fachbereichs Medizin, Herrn Univ -Prof Dr M Thelan, Am Pulverturm 13, 6500 Mainz, Tel.. 06131/17-3180 (W6742)A

KING'S COLLEGE LONDON

Biomolecular Sciences Division

We are seeking a cellular immunologist or protein chemist to work on a three-year Asthma Research Council-funded project on the receptors for human immunoglobulin E Experience in the field of receptors would be useful Starting salary up to £13,386 inclusive Please send CV and the names of two referees to **Mr D M Drummie, King's College London, 26–29 Drury Lane, London WC2B 5RL** by 10 December 1989 Enquiries may be made to Prof H J Gould on 01-836 8851

(2151)A

FORSCHUNGSINSTITUT BORSTEL
DIVISION OF BIOCHEMICAL MICROBIOLOGY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for an initial 2-year postdoctoral position to work on surface structures of *Chlamydia* and their role during infection

Applicants should preferably have experiences in chlamydiology, molecular biology of procaryotes, or cell biology

For further details contact Dr H Brade by phone (04537/10474) or by fax (04537/10404) Please send applications including CV and the names and addresses of two referees to **Forschungsinstitut Borstel, Personalwesen, Parkalles 1-40, D-2061 BORSTEL, FRG** (2171)A

DIRECTOR, HIGH ALTITUDE OBSERVATORY

The National Center for Atmospheric Research in Boulder, Colorado is accepting applications for Director of the High Altitude Observatory The Director provides leadership to a broad research program in solar physics and related areas, with a balanced emphasis on observation, data interpretation, and theory Primary responsibilities include the formulation and implementation of scientific plans and priorities, selecting, developing and managing the Observatory's staff in ways consistent with NCAR's equal employment opportunity policy, and planning and managing budgets and the allocation of resources

The candidate must meet the qualifications of an NCAR Senior Scientist, which include possession of a Ph D in an appropriate physical science OR an equivalent combination of education and experience, and, in this particular case, international recognition as a scientific leader in solar physics, solar-terrestrial physics, and/or related areas based on published research works Also essential are demonstrated abilities and skills in the development of scientific programs, the persuasive promotion of scientific goals and strategies, and the effective management and advancement of the Observatory's work with NCAR, UCAR, funding agencies, and the general scientific community Salary range is $5,720-$8,580/month

Send curriculum vitae and a list of publications by January 31, 1990 to **Job #1149, Searl G Brier, NCAR, P O Box 3000, Boulder, Colorado 80307** NCAR is an AA/EO Employer Applications from women, minorities, the disabled, and Vietnam Era and special disabled veterans are encouraged

CLINICAL PHARMACOLOGIST - PHYSIOLOGICAL PHARMACOKINETICIST

The Laboratory of Clinical Studies, National Institute on Alcohol Abuse and Alcoholism, Public Health Service, invites applications for one Clinical Pharmacologist - Physiological Pharmacokineticist This position is offered depending on the experience of the applicants at the level of a senior staff fellow (salary range, $28,000 - $45,234) The Laboratory is involved in exciting studies on brain imaging and drug metabolism The individual appointed will have an important role in this multidisciplinary team effort A research ward, excellent analytical chemistry, brain imaging and computer resources are available in the Laboratory on the NIH campus Position information and qualification requirements may be obtained by contacting Dr Linnoila Submit Curriculum Vitae and names of three references to

Markku Linnoila, M D , Ph D
Clinical Director
National Institutes of Health
Building 10, Room 3B-19
9000 Rockville Pike
Bethesda, MD 20892
(301) 496-9705

This position is now available

NIH IS AN EQUAL OPPORTUNITY EMPLOYER

(NW4533)A

DIRECTOR OF RESEARCH

Our client is rapidly establishing itself as one of the leaders in the development and exploitation of biomaterials technology

As the first applications of its proprietary technology approach the market, the Company is committed to further commercialisation and is expanding its technology base by developing other innovative ideas

In order to accelerate the rate of progress, the Company wishes to appoint a Director of Research, who will report to the Chief Executive Officer In addition to advising the C.E O. and the Board on the Company's scientific strategy, the Director of Research will be expected to direct a team of young, dedicated scientists and to lead by example

This demanding position requires potential candidates to have experience in polymer chemistry or materials science, preferably holding a doctorate in one of these disciplines He/she will also be required to demonstrate a proven record of scientific innovation

Candidates may currently be working in industry, or in an academic environment with industrial contacts

The demands on the new Director will be high, but so will be the rewards

For further information please contact Ken Cooper at the address below Alternatively telephone 01-499 6427

INDERMAUR INTERNATIONAL LIMITED

EXECUTIVE SEARCH CONSULTANTS

(2121)A

26 Upper Brook Street, London W1Y 1PD

As part of the expansion of the DSM – German Collection of Microorganisms and Cell Cultures in Braunschweig (F R G), an institution owned by the State of Lower Saxony, three positions as

Cell Biologist
Virologist
Cytogeneticist

are available

The positions will be within the newly formed human and animal cell culture collection

The successful applicants should have scientific experience in cell culture techniques and have an in depth knowledge of his/her specialist area The candidates must have a Ph D and demonstrated commitment and potential for basic research

His/her duties will be to participate in establishing a new culture collection and to provide expertise for the investigation of the animal and human cell lines as part of the service provided by the institute Furthermore, he/she will be expected to take an active part in developing and carrying out research in this area

The salary will be on the German Federal Employees Scale (BAT IIa/Ib) Applicants should submit a letter of application, curriculum vitae, list of publications, and the names, addresses and telephone numbers of referees to

Dr Hans G Drexler
DSM – Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH
Mascheroder Weg 1B
D-3300 Braunschweig, F R G
Tel (0531) 618760

Closing date for applications 31 12 89 (W6746)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES
LECTURER IN MICROBIOLOGY

Applications are invited from microbiologists in the field of microbial physiology for a Lectureship in the Department of Biological Sciences

The person appointed will be required to contribute to teaching to Honours BSc level in general microbiology and to rapidly establish a research programme The Department offers degrees in biology, botany, microbiology, microbiology with genetics and zoology and a high level of integration across the life sciences in teaching and research exists There are currently 21 academic staff, 20 post-doctoral fellows and over 50 post-graduate research students Research figures very highly in Departmental activities, supported by the Research Councils, Government Agencies, and UK and overseas industry Current areas of research in microbiology include cyanobacterial physiology and toxicology, metal accumulation and tolerance in microbes, microbial osmoregulation, molecular genetics of microbial drug resistance, microbial mat ecology and several aspects of biotechnology Interaction with these areas would be welcomed, although applicants with experience and plans in other areas of microbial physiology are also encouraged to apply

The Lectureship is available from 1 January 1990 and appointment will be made on the Lecturer Grade A scale (£10,458-£15,372) or, for a well qualified and experienced candidate, on the Lecturer Grade B scale (£16,014-£20,469)

Informal enquiries should be made to Professor G A Codd, Department of Biological Sciences, telephone (0382) 23181 extension 4767

Letter of application with CV (6 copies or, if posted overseas, one copy in a format suitable for photocopying) and the names and addresses of three referees to the **Personnel Office, The University, Dundee, DD1 4HN** Please quote reference EST/44/89/N

Closing date 14 December 1989 (2150)A

CELL BIOLOGY

SENIOR LEVEL FACULTY POSITION

DEPARTMENT OF BIOLOGY
UNIVERSITY OF CALIFORNIA, RIVERSIDE

Applications are invited for a tenured senior level (Associate/Full Professor) faculty position in the Department of Biology Preference will be given to scientists applying modern molecular approaches to the study of the cell All areas of cell biology will be considered However, we are particularly interested in individuals concerned with cell–cell interactions, protein sorting and assembly, cytoskeletal structure and function, or the extracellular matrix

Applicants should have an active research program and an established reputation with a proven record of competing successfully for extramural funding Demonstrated interest and ability in teaching is sought Salary will be competitive and will depend on qualifications and experience

Modern research space and access to major equipment such as TEM, SEM, and staffed biotechnology and analytical chemistry instrumentation facilities are available

Applications must be received by January 15, 1990 Please send *curriculum vitae*, summary of research interests and arrange to have letters sent by three to five referees to

Chair,
Cell and Molecular Biology Search Committee,
Department of Biology,
University of California, Riverside, CA 92521

The University of California is an Equal Opportunity/ Affirmative Action Employer and minority and female candidates are encouraged to apply (NW4589)A

MOLECULAR BIOLOGIST

(RESEARCH FELLOW)

A$31,525 to A$38,567 per annum

Division of Plant Industry
CANBERRA ACT

THE DIVISION The CSIRO Division of Plant Industry conducts research on problems fundamental to plant biology and agricultural production Prominent among the research activities are programs concerned with gene transfer and expression, cell culture, herbicide biology and synthesis, photosynthetic processes and biological nitrogen fixation

THE JOB The appointee will undertake research on chloroplast development The project involves the molecular cloning of two nuclear genes from maize that regulate chloroplast development Both genes are being tagged with transposable elements to facilitate cloning Once cloned, the role of each gene product in leaf development will be determined This project will be part of a larger research program studying environmental and developmental regulation of nuclear genes that code for chloroplast proteins

THE PERSON Applicants should possess a PhD or equivalent qualifications, research achievement in molecular biology, genetics, biochemistry or a related field and experience with DNA cloning are essential Experience with eukaryotic genetics and a knowledge of plant development and cell biology would be an advantage

CONDITIONS Appointment will be for a term of 18 months with possibility of an additional 24 months Australian Government Superannuation benefits are available

MORE INFORMATION Prospective applicants are invited to telephone Dr W C Taylor on 6162 46 5223 for further information A copy of the detailed duty statement and selection criteria may be obtained by telephoning 6162 46 5206

APPLICATIONS Applications should be submitted by 5 January 1990 and quote reference number N8925 They should be framed against the selection criteria, and state relevant personal particulars including details of qualifications and experience Applicants should give details of at least two referees, and address their applications to

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

POSTDOCTORAL TRAINING IN CELL REGULATION

The Department of Biochemistry, St Jude Children's Research Hospital, announces a training program in the molecular and cellular biology of cell growth, differentiation and transformation The program emphasizes a multidisciplinary approach that develops skills in biochemistry, molecular genetics and cell biology Fellows benefit from training in energetic, well-funded laboratories within an expanding research institute We offer competitive stipends plus the benefit of living in a growing, economical, sunbelt community Specific research groups participating in the program include

W Y Cheung	Regulatory properties and biological functions of calmodulin, Ca^{2+} regulated enzymes
J Cleveland	Growth factor signal transduction and regulation of gene transcription
V A Fried	The ubiquitin system and post-translational regulatory pathways
J N Ihle	Mechanisms of hematopoietic stem cell growth regulation, differentiation and transformation
S Jackowski	Regulation of phospholipid metabolism and the production of lipid-derived second messengers
C Rock	Cell cycle regulation of membrane biogenesis
E Thomas	Antimicrobial and antitumor mechanisms of leukocytes

Further information on individual research programs can be obtained by writing the Department of Biochemistry Applicants should indicate the research group(s) they are interested in, submit a brief statement of their research interests, curriculum vitae, reprints, and names of three references to

An Equal Opportunity/Affirmative Action Employer

(NW4568)A

UNIVERSITY OF CALIFORNIA, DAVIS
BODEGA MARINE LABORATORY

POPULATION BIOLOGIST

The Bodega Marine Laboratory, a research unit of the University of California, Davis, invites applications for a position in population biology The position is open at the tenured level — associate and full professor Applicants must have a Ph D (or equivalent), and demonstrated excellence in their fields We particularly encourage scientists to apply whose research will take advantage of the diverse ecosystems of the Northern California coast where the Laboratory and its surrounding natural reserve are located In addition to research, teaching and advising responsibilities, the appointee will serve as the Laboratory's coordinator for research and instruction in population biology, alongside counterparts from organismal biology and aquaculture and fisheries The position is at the Laboratory full time, although the appointee will also be a member of an appropriate department on the Davis campus

Applicants should provide a letter of research and teaching interests, *curriculum vitae*, two selected reprints, and the names, addresses and phone numbers of three references to **Dr James B Clegg, Bodega Marine Laboratory, P O Box 247, Bodega Bay, CA 94923**

The Selection Committee will begin review of applications on 15 January 1990, the position will remain open until filled

The University of California is an Equal Opportunity/ Affirmative Action Employer (NW4631)A

A leading pharmaceutical Company actively involved in new drug discovery in a range of therapeutic areas, is seeking a

HEAD OF DRUG METABOLISM

He or she will lead a group dealing with the disposition and metabolism of candidate compounds in animals and man

This group is in the Department of Pharmacokinetics and Metabolism, of R & D division, based in Italy

Applicants should have a PhD in chemistry, biochemistry or in a biological area, with several years post-doctoral experience in drug metabolism and a sound knowledge of the role of drug metabolism studies in drug development

Candidates should send a curriculum vitae including a list of publications, names and addresses of references with **Rif A–1639 evidenced on the envelope** to

CITY University

DEPARTMENT OF OPTOMETRY AND VISUAL SCIENCE

Manager-Electron Microscopy
To £23,826

This is a new and exciting post responsible for running and developing the commercial potential of our electron microscopic laboratory This houses a JEOL JEM 1B instrument with facilities for transmission, scanning and X-ray analysis Your responsibilities will include maintaining equipment, liaising with users, service work, and instructing staff and project students without user experience

As well as managing University-related activities, you will have the flair to market commercial opportunities with other academic and industrial concerns—mainly in the biological tissue area

Experience in the use of EMs and back-up equipment is essential, and knowledge of biological structure would be a distinct advantage Salary will be on the scale £20,340-£23,826 inclusive of London Allowance A performance related bonus scheme is under active consideration This appointment is for 3 years in the first instance

For further details, please contact Professor G L Ruskell, Department of Optometry and Visual Science, City University, Northampton Square, London EC1V 0HB Tel 01-253 4399, Ext 4305

Free University of Brussels —
Institute of Interdisciplinary Research
Profs J.E Dumont – G Vassart

POST DOCTORAL POSITION
TRANSGENIC MICE PROGRAM

A two year position, starting immediately, is available to participate in the development of a newly set up transgenic mice team in Brussels The research project will involve the following themes

- Oncogenesis of the thyroid
- Oncogenic potential of specific viral genes
- Development of homologous recombination in ES cells, with the aim of generating transgenic models of receptor deficiency

Applicants should have a strong background in molecular biology techniques Additional experience in microinjection techniques, cell culture, or ES cells handling would be an advantage

Applications, including a C V and names of two referees, should be sent to **Dr M Parmentier, I R I B H N., ULB Campus Erasme, 808 route de Lennik, 1070 Brussels, Belgium** (02/526 41 72) (W6739)A

Institute of Terrestrial Ecology

MOLECULAR BIOLOGIST/ PLANT POPULATION ECOLOGIST

Furzebrook, Dorset

A population geneticist with interest and experience in the application of DNA technology to ecological and population studies is required The successful candidate will join a small team at ITE Furzebrook working on the population ecology and genetics of a range of eukaryotes and will be expected to apply DNA techniques to natural populations of plants, (initially *Brassica oleracea*) to investigate population substructuring and gene flow He/she will also be required to assist in the technical training of staff working on relatedness in animal populations, and the development of molecular methods within the Institute

Applicants will be expected to have been awarded a PhD in a plant genetic subject Experience with RFLP analysis and DNA fingerprinting and the development of DNA probes is vital

The appointment is for three years Salary will be in the range of **£10,678** to **£14,909** per annum, or **£13,254** to **£18,864** per annum depending upon qualifications and experience Benefits include generous holidays and a non contributory pension scheme

The Institute of Terrestrial Ecology is a component body of the Natural Environment Research Council

Further information and application forms may be obtained from the Station Secretary, Institute of Terrestrial Ecology, Furzebrook Research Station, Wareham, Dorset BH20 5AS, or by telephoning 09295-51518/9

Closing date for receipt of application forms, including a full curriculum vitae, is 7th December 1989

RHM RESEARCH AND ENGINEERING LTD

HEAD OF BIOCHEMISTRY

Do you have a good honours degree in Biochemistry or Chemistry followed by a PhD and at least five years postdoctoral experience? Can you demonstrate a good track record in the application of your science? Do you have experience of managing other scientists? Right now we may have the opportunity for which you have been waiting which will allow you to combine your scientific and personal skills to meet the challenges and opportunities of the 90's in the food manufacturing industry

Ranks Hovis McDougall is a major international manufacturer of foods as Hovis, Mr Kipling, Shredded Wheat, Robertsons, Bisto, Sharwood, and the new mycoprotein Quorn

The Lord Rank Research Centre, pleasantly situated in the Chiltern Hills at High Wycombe, is the corporate multidisciplinary research and development organisation for RHM and provides a lively, stimulating and well equipped working environment

We wish to recruit a Senior Biochemist to lead our team of scientists undertaking studies of the chemistry and biochemistry of raw materials and products

Reporting to the Head of Food Science you will be expected to initiate, develop and apply fresh ideas to our project studies as well as managing and developing the skills and career aspirations of the people in the Biochemistry Section You must therefore have a creative mind, good communication skills and the ability to win the respect of colleagues through leadership and scientific excellence

The RHM Group offers its scientists the rewards, training and career development opportunities expected of a major international company

Interested? The send your CV, quoting reference 513, to

CELL BIOLOGY

DEVELOPMENTAL NEUROBIOLOGY

Two senior level faculty positions

Department of Biology
University of California, Riverside

The Department of Biology, University of California, Riverside, invites applications for two openings at the senior level. One is in cell biology, at the Associate or Full Professor level; the other is in developmental neurobiology at the Full Professor level The appointments will be effective July 1, 1990. Applicants should have an active research program, and an established reputation with a proven record of competing successfully for extramural funding. Demonstrated interest and ability in teaching is sought Salary will be competitive and will depend on qualifications and experience. Modern research space and access to major equipment such as TEM, SEM, and staffed biotechnology and analytical chemistry instrumentation facilities are available.

CELL BIOLOGY

We are interested in all areas of research in cell biology. Preference will be given to scientists applying modern molecular approaches to the study of the cell and with interests in: cell/cell interactions, protein sorting and assembly, cytoskeletal structure and function, or extra-cellular matrix. Applications should be received by January 15, 1990. Please send *curriculum vitae,* summary of research and teaching interests, and arrange to have 3-5 referees send letters to:

Cell and Molecular Biology
Search Committee,
Department of Biology,
University of California,
Riverside, CA 92521.

SCIENTIFIC DIRECTOR SUPERCOMPUTER FACILITY

The National Cancer Institute's supercomputer facility is a totally integrated Class VI computer center devoted to problems in biomedical research and is managed by Program Resources, Inc at the Frederick Cancer Research Facility in Frederick, Maryland Users have convenient access to a CRAY X/MP 24 supercomputer, VAX minicomputers (8600 and 11/785), SUN, Apollo, Silicon Graphics, Evans and Sutherland graphics workstations, and a variety of microcomputers all networked by an Ethernet local area network High speed communications networks extend user access to other research organizations and universities through the nationwide internets (ARPANET, NSFNET, BITNET) Research applications include Sequence Analysis, Structure Prediction, Molecular Graphics, Image Processing, Structure Determination, Crystallography, MRI, Statistical Analysis, and Data Base Analysis

The candidate we seek will be responsible for directing and coordinating the scientific programs of the supercomputer facility which has a broad user base focusing on contemporary problems in biomedical research with special focus on the NCI's mission in Cancer and AIDS research

This facilty is being considered for upgrade, thus the Scientific Director will have a major role in the establishment of design and instrumentation upgrades and will have an opportunity to carry out research consistent with broad program goals The Scientific Director will be supported by an outstanding incumbent technical and administrative staff of 29 employees

Ph D or M D degree with demonstrated expertise in drug design, 8-10 years of related experience and a national reputation directing scientific programs is required along with detailed knowledge and direct experience with supercomputer hardware and technology

PRI offers a salary commensurate with credentials and a comprehensive company benefits program including a 401(k) Retirement Plan and relocation assistance

For consideration please send resume, references, publications list, and salary requirements on behalf of the Supercomputer Scientific Director Search Committee to

AFRC INSTITUTE FOR ANIMAL HEALTH
PIRBRIGHT, WOKING, SURREY GU24 0NF

MOLECULAR BIOLOGIST/ VIROLOGIST (SENIOR SCIENTIFIC OFFICER)

to work on

MOLECULAR BIOLOGY AND IMMUNOLOGY OF RINDERPEST VIRUS — A 5 YEAR RESEARCH PROJECT FUNDED BY THE WELLCOME TRUST

Rinderpest virus is a serious veterinary pathogen, closely related to measles and canine distemper virus, which affects ruminants in many developing countries It is an excellent model for the study of virus pathogenicity in the natural host at the molecular level since strains differing greatly in their virulence have been isolated

A SENIOR SCIENTIFIC OFFICER is required for research on the analysis of the structure and function of virus proteins using molecular biological techniques

Minimum qualifications A good degree in an appropriate subject plus a PhD and 4 years relevant experience

Salary £13,254-£18,864 according to qualifications and experience Non-contributory superannuation scheme

Informal enquiries can be made by phone (0483 232441) or letter to Dr T Barrett or Dr C J Bostock

Applications with curriculum vitae and the names of two referees to the Laboratory Administrator at the above address (2131)A

MICROBIOLOGIST

ASSISTANT, ASSOCIATE, OR PROFESSOR

The Department of Microbiology, University of California at Davis invites applications for an 11-month, tenure-track, open rank position from candidates who have demonstrated excellence in microbiological research The candidate will join a strong, supportive and growing Department with strength in diversity, physiology and genetics Teaching responsibilities include graduate and/or undergraduate courses in bacterial physiology and genetics Please send a curriculum vitae, selected publications, a statement of proposed research, a description of teaching experience and interests, and the names of three references to **Dr J C Meeks, Chair, Physiology/Genetics Search Committee, Department of Microbiology, University of California, Davis, CA 95616**

The position will remain open until filled, however, to be assured of consideration, applications should be received by February 1, 1990

The University of California is an Affirmative Action/Equal Opportunity Employer Women and Minorities are encouraged to apply (NW4597)A

UNIVERSITY OF EDINBURGH

Department of Microbiology

POST-DOCTORAL RESEARCH FELLOW

Applications are invited for an MRC funded post-doctoral research assistant position in the laboratory of Dr M P Gallagher The project involves molecular characterisation of the nucleoside permeases of *Salmonella typhimurium*, using current techniques of molecular genetics/biology, immunology and biochemistry The system serves as a model for cancer therapy and it is hoped that the study will unravel key features of permease assembly and substrate specificity, as well as regulation of permease synthesis in this organism Experience in bacterial genetics, molecular biology (cloning and sequencing) or membrane biochemistry is preferable but not essential

The position is for three years and is available immediately but starting date is negotiable for an appropriate candidate Starting salary will be between £10,458 and £12,381 depending on age and experience

Informal enquiries and applications, including C V and the names and addresses of two referees, to **Dr M P Gallagher, Department of Microbiology, University of Edinburgh, Kings Buildings, West Mains Rd , Edinburgh EH9 3JG, U K** (telephone 031-6671041 xt 268 or FAX 031 667 2601) by 15 December, 1989

PLEASE QUOTE REFERENCE NO 5726 (2158)A

UNIVERSITY OF DURHAM

Department of Geological Sciences

SENIOR RESEARCH ASSISTANT IN SPACE GEODESY

Applicants are invited for the post of Post Doctoral Research Assistant in Global Positioning System (GPS) Geodesy, to participate in the research effort at Durham, and be responsible for the processing of GPS data Candidates should hold a Ph D degree and preferably have a background in Geodesy and Computing Consideration will also be given to applicants with a background in Geophysics Informal enquiries concerning the appointment may be made to Dr G R Foulger (tel 091–374–2514)

The appointment, which is funded by the Wolfson Foundation, will be from early 1990 for up to three years The salary will be within the Research and Analogous 1A scale (£10,458–£16,665), according to experience

Further particulars may be obtained from the Registrar, Science Laboratories, South Road, Durham, DH1 3LE, tel 091–374–2265, to whom applications (three copies, including full CV and the names of three referees) should be sent not later than Friday, 29th December, 1989 Please quote ref GL3 (2126)A

THE UNIVERSITY OF LEEDS

Department of Earth Sciences

RESEARCH ASSISTANT/FELLOW

Applications are invited for the above post for a fixed period of two years for work on geophysical research, especially in geomagnetism applied to the Earth's deep interior and the geophysical fluid dynamics of the Earth's core, involving the use of a SUN4 computing system, as part of a first rate research group

A good honours degree in Mathematics, Physics or Geophysics is required, and further qualifications/experience in computing, particularly FORTRAN programming and the use of UNIX-based systems, would be an advantage

Salary for Predoctoral Research Assistant on R/A Grade IB (£9,816–£12,381) or, for Postdoctoral Research Fellow, on R/A Grade IA (£10,458–£16,665) according to qualifications and relevant experience Candidates for Research Fellow should have a PhD or equivalent experience

Informal enquiries may be made to Dr K A Whaler (tel (0532) 335216)

Application forms and further particulars may be obtained from, and completed applications forwarded to, **The Registrar, The University, Leeds LS2 9JT** (tel (0532) 333969 — direct line), quoting reference no 49/41

Closing date for applications 14 December 1989 (2128)A

ELECTRON MICROPROBE ANALYST
and
TRANSMISSION ELECTRON MICROSCOPIST

The University of Alabama is seeking an electron microprobe analyst to operate a new JEOL 8600 electron microprobe (EMP) and a transmission electron microscopist to operate a new Hitachi H-8000 transmission electron microscope (TEM) The EMP is equipped with 5 wavelength dispersive spectrometers, TN 5600 automation, a TN 5402 energy dispersive X-ray analyzer, and a TN 5702 digital image analysis system The TEM is equipped with a STEM attachment, a TN 5502 X-ray detector, and a signal processing system Both instruments are located in the central analytical facility of the new Tom Bevill Energy, Mineral, and Material Science Research Building which houses a variety of electron optical, X-ray, spectrographic, and chromatographic analytical equipment

The EMP analyst and TEM microscopist will supervise operation of the instruments, perform analyses for researchers, and train users in routine analytical procedures Experience in the following areas is considered an asset for the EMP analyst 1) microprobe techniques and X-ray data correction methods for geological materials, 2) mineral chemistry and petrology, 3) computer programming, and 4) EMP maintenance Experience in the following areas is considered an asset for the TEM microscopist 1) TEM/STEM techniques for materials science, 2) thin-film research, 3) quantitative analytical microscopy, and 4) high-resolution microscopy The EMP analyst and TEM microscopist are expected to participate in on-going research projects and will be encouraged to carry-out their own research

The EMP analyst should have a M S in Geology, but candidates with expertise in some or all of the above fields will be considered The TEM microscopist should have a degree in Natural Sciences or Metallurgy, work experience in a research environment is desirable Salaries will be commensurate with experience Applications must be received before February 1, 1990, appointments begin March 1, 1990 Send a letter of application, vitae, and the names of three references to **Dr Jen-Ho Fang, Chairman, Department of Geology, Box 870338, University of Alabama, Tuscaloosa, Alabama 35487**

The University of Alabama is an equal opportunity/affirmative action employer

(NW4611)A

FULL PROFESSOR
VISION RESEARCH

Applications and nominations are invited for a tenured faculty research position at the level of Professor in the Eye Research Institute of Oakland University The candidate must be an established investigator with Ph D , M D or equivalent, a minimum 10 years experience in independent research, a strong publication record and, where appropriate, proven ability to secure continuous external grant support We are particularly interested in established scientists in molecular biology or immunology who have, or will make, a strong commitment to vision research Investigators in other areas of biomedical sciences who will make the same commitment will also be considered

Opportunities exist for collaboration with current faculty who are engaged in research in the biochemistry, physiology and molecular biology of the cornea, lens, retina and intraocular fluids In addition, collaboration on clinical research projects is also possible with faculty and residents of the affiliated Department of Ophthalmology of a major area hospital

The Eye Research Institute is an independent academic unit of Oakland University, a state supported institution situated on a 1400 acre campus, 25 miles north of Detroit, with an enrollment of 9500 students in baccalaureate and doctoral programs

Applicants should send a curriculum vitae, 3 to 5 reprints and the names of three references by February 16, 1990 to **Dr M V Riley, Chair, Search Committee, Eye Research Institute, Oakland University, Rochester, MI 48309**

An Equal Opportunity/Affirmative Action Employer (NW4617)A

BROWN UNIVERSITY
ASSISTANT PROFESSOR OF MEDICAL SCIENCE (ARTIFICIAL ORGANS AND BIOMATERIALS)

For a full-time regular position as Assistant Professor of Medical Sciences we are seeking a broadly trained chemical engineer/polymer scientist whose research interests are in the area of biomaterials with emphasis on surface modification and tissue-material interaction A Ph D or equivalent degree is required Some biology background and postdoctoral research experience are preferred The position is linked to the Artificial Organ/Biomaterials Program, a multidisciplinary group of faculty and graduate students, with current emphasis on tissue-material interactions, bioresorbable polymers, and the development of membrane-protected tissue transplants Candidates should demonstrate outstanding potential to develop an independent externally funded research program The position requires teaching survey courses in the field of polymer science and biomaterials and guidance of Ph D and M D -Ph D students The appointment can begin between July 1 and December 31, 1990

To ensure full consideration, applications should be received by February 16, 1990 Applicants should submit curriculum vitae, a set of representative reprints, a concise description of research interests and goals, and should arrange for three letters of reference to be sent to **Professor E H Leduc, Division of Biology and Medicine, Box G, Brown University, Providence, RI 02912** *We encourage applications from women and minority candidates Brown University is an Equal Opportunity Affirmative Action Employer* (NW4636)A

Department of Neurobiology
Duke University Medical Center

Applications are invited for 11 new tenure track positions at all ranks in the newly created Department of Neurobiology at Duke University Medical Center investigators will occupy research space in the Joseph and Kathleen Bryan Neurobiology Building scheduled for completion in February 1990 and will be leaders in university wide graduate and undergraduate programs in neuroscience Applicants with strong research records are being solicited from the full range of sub fields in neurobiology including molecular cellular systems, and behavioral approaches Minimal qualifications include an M D or Ph D degree and several years of research experience in neurobiology The positions will be available from the fall of 1990

Applicants should submit a curriculum vitae a statement of research interests and objectives and letters from at least 3 references to Dr Dale Purves, Chairman, Department of Neurobiology, Box 3209, Duke University Medical Center, Durham, North Carolina 27710

Duke University offers highly competitive salaries and benefits Eligible employees enjoy outstanding educational opportunities including educational assistance and tuition grants for children (NW4609)A

Duke University

A Universe Of Opportunity

Duke University is an Equal Opportunity/Affirmative Action Employer

Celgene

MICROBIOLOGIST/BIOCHEMIST CHEMIST/ENZYMOLOGIST

Celgene Corporation is a leader in the application of biotechnology to the chemical industry The recent development of novel proprietary technology has led to the creation of two high-profile, post-doctoral research opportunities within its **CHIRAL PRODUCTS PROGRAM.**

These positions provide opportunities to gain industrial research experience in the application of biocatalysis to the resolution and synthesis of commercially-valuable chiral molecules The successful applicants will be highly motivated individuals who will develop new areas of research as part of a multidisciplinary group These positions will appeal particularly to scientists with research experience or interest in microbial product formation or the chemistry of enzyme action

Celgene Corporation is a well-funded public company committed to becoming the premier name in chemical biotechnology Qualified candidates should send a detailed resume, indicating position of interest to **Personnel Department NM, Celgene Corporation, 7 Powder Horn Drive, Warren, NJ 07060.**

An Equal Opportunity Employer M/F (NW6435)A

UNITED MEDICAL AND DENTAL SCHOOLS OF GUYS AND ST THOMAS"S HOSPITALS

VIROLOGY **RESEARCH ASSISTANT**

required to join a team at St Thomas's Campus and the University of Surrey to study the immunodominant epitopes of rubella virus and to produce recombinant and synthetic antigens Experience of virological techniques essential, and molecular biological techniques and advantage PhD desirable, but not essential Further information from 01 928 9292 ex 2453 Salary in range £9,816–£12,381 per annum plus £1,650 London Weighting To apply send CV and names of two referees to the **Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** quoting ref STH/VIR/451 by 14th December 1989 (2161)A

UNIVERSITY OF BRISTOL
DEPARTMENT OF PHYSIOLOGY
LECTURESHIP

Applications are invited for the above post on the Grade A scale (£10,458-£15,372) or Grade B scale (£16,014-£20,469), depending on age and qualifications, from active and successful researchers who are also enthusiastic teachers The department's current research interesrts are in four main areas membrane and cell biophysics, muscle and motility, sensory mechanisms in the CNS and motor control The department teaches Physiology and Histology to Science, Medical, Veterinary and Dental students, and would expect the new appointee to be willing to teach in any area

Shortlisted candidates will be expected to deliver to the department a first-year undergraduate lecture of their choice on January 18th and a short seminar on their research on the morning before interview on January 19th

Applications, in the form of a detailed curriculum vitae with an explanatory letter giving names and telephone numbers of three referees, should be sent to the **Registrar, Senate House, Bristol, BS8 1TH,** to be received by January 5th 1990 Please quote reference CYF 2

Further particulars from Dr J Luck, Physiology Department, Bristol University, BS8 1TD, telephone (0272) 303465, who will be happy to show potential applicants round the department

An equal opportunities employer (2125)A

DEPARTMENT OF VISUAL SCIENCE
Institute of Ophthalmology Judd Street, London, WC1H 9QS

We have vacancies for

Postdoctoral Research Assistants

on work related to the transfer of the retinal input through subcortical visual areas

1 **ELECTROPHYSIOLOGIST** This position is for three years and is intended to study the mechanism(s) underlying the action of GABA in thalamic nuclei with special emphasis on the lateral geniculate and the perigeniculate nucleus using brain slice and single electrode voltage clamp techniques
2 **ELECTROPHYSIOLOGIST** This position *is for an initial period of 18 months and is intended to investigate the voltage activated* conductances underlying the rhythmic activity of thalamocortical cells activity using brain slice and single electrode voltage clamp techniques
3 **NEURONAL MODELLING** This position is for two years and involves the development of computer simulations of thalamocortical cells activity and *their modulation by retinal and cortical inputs*

   For positions 1 and 2 previous experience in *in vitro* electrophysiological techniques is advantageous but not essential For position 3 experience in computer modelling and knowledge of neuronal simulation techniques is highly desirable

These three positions are funded by The Wellcome Trust *with salary in the range* £14,703 £16,014 *plus* £1,650 London Allowance Applications, with curriculum vitae and the names of two referees, should be sent to Dr V Crunelli at the above address, from whom further particulars can be obtained (Tel 01 387 9621 ext 233)

4 **NEUROPHYSIOLOGIST** This position is *for three years and is funded by the MRC — project entitled "Transmitters of visual and somatosensory afferents* to the superior colliculus" Experience of neuro physiological and/or neuro pharmacological techniques (especially in relation to amino acid transmitters or sensory systems) would be an advantage, although not essential

For this position salary will be in the range £12,381 £13 527 plus £1 650 London Allowance Applications, *including curriculum vitae* should be sent to Dr T E Salt at the above address (Tel 01-387 9621 ext 231) (2162)A

THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON

POST-DOCTORAL RESEARCH ASSISTANT

A Post-Doctoral Research Worker is required for a two year period

The successful applicant will have experience in phytochemistry and particularly in the isolation and structure determination of natural products The research to be carried out forms part of the collaborative programme established under the 1989 Award for the Advancement of European Science funded by the Korber Foundation It is proposed that the research will include whole plant material, plant tissue cultures and pharmacological investigations Enquiries to Professor J D Phillipson, Department of Pharmacognosy, The School of Pharmacy, 29-39 Brunswick Square, London, WC1N 1AX Tel 01 837 7651

Salary scale from £11,108 to £18,315 depending upon experience

Applications in the form of a CV and naming two referees should be submitted to the **Assistant Secretary** at the above address no later than 15 December 1989 (2136)A

MEDICAL RESEARCH COUNCIL NATIONAL INSTITUTE FOR MEDICAL RESEARCH

POSTDOCTORAL SCIENTIST

Applications are invited for a short-term (three year) postdoctoral position with Dr Jack Price in the Laboratory of Embryogenesis to work on cell lineage in the central nervous system using retroviral vectors

The work will involve molecular biology, tissue culture and neuroanatomy, some experience of one or more of these areas would be an advantage Further information about the nature of the work can be obtained from Dr Price on 01-959 3666 extension 2220 The salary will be in the range £12,381 to £20,469 (starting salary dependant on experience) plus £1,650 per annum London Allowance MRC Pension Scheme option

Applications including a curriculum vitae, list of publications and the names and addresses of two professional referees should be sent to **Mr C R Russell, Administrative Manager, National Institute for Medical Research, The Ridgeway, Mill Hill, London, NW7 1AA,** not later than 15th December 1989 *quoting reference number* PEG/0189

(2156)A

MOLECULAR GENETICIST

THE UNIVERSITY OF RICHMOND

invites applications for a tenure-track position in biology at the assistant professor level The primary teaching responsibility will be to coordinate and teach a core curriculum undergraduate course in molecular genetics and, on occasion, teach an undergraduate course in immunology In addition, the appointee will be expected to develop advanced undergraduate and MS-level courses in molecular genetics areas Preference will be given to those who will develop an active research program in molecular genetics involving undergraduate students Candidates must have the Ph D degree and post-doctoral experience is desirable

Submit resume, undergraduate and graduate transcripts, a statement of research plans and three letters of reference to **Dr F B Leftwich, Department of Biology, University of Richmond, VA 23173** Consideration of applications will begin on January 30, 1990

The University of Richmond is an equal opportunity/affirmative action employer and encourages applications from women and minority candidates (NW4605)A

EMORY UNIVERSITY

Faculty Positions in Developmental Biology

As part of a major expansion, the Department of Biology intends to make several tenure-track appointments in developmental biology Presently available positions are at the assistant professor level, although an appointment at a higher rank could be considered in exceptional circumstances The area of research interest is broadly defined to encompass the study of molecular mechanisms relevant to the fundamental processes of differentiation and morphogenesis Applicants should provide evidence that they will develop a strong, independent research program and that they possess a broad knowledge of developmental biology Applications from minority and female candidates are strongly encouraged

Please send a curriculum vitae, reprints of publications, a statement of present and future research plans, and four letters of recommendation to **Developmental Biology Search Committee, Department of Biology, Emory University, Atlanta, GA, 30322** To ensure full consideration, applications should be received by December 31, 1989

Emory is an Equal Opportunity/Affirmative Action Employer

(NW4607)A

The University of California, San Diego is seeking a Ph D applicant for a position of **Assistant Research Biochemist** Candidates should be a molecular genetist with experience in retrovirology, cell biology, histochemistry and neuroanatomy Focus of the research will be in the area of gene therapy in the central nervous system Salary range based on University of California policy Interested individuals should send curriculum vitae with a list of three references no later than December 15, 1989 **Theodore Friedmann, M D , Professor, Department of Pediatrics, UCSD/M034 La Jolla, CA 92093** *Equal Opportunity/Affirmative Action Employer* (NW4627)A

LABORATORY SPECIALIST

needed for studies involving viruses and viral DNA, virus isolation and infection, restriction enzyme analysis, Southern and Northern blotting, and molecular cloning

Salary \$7.80 per hour

Require Masters Degree in Molecular Biology, knowledge of molecular cloning techniques and viral biology and ability to use restriction analysis, gel electrophoresis and DNA hybridization Job Order No. 3941890

Contact **Utah Job Service, 1234 South Main Street, P.O. Box 11750, Salt Lake City, Utah 84147** (NW4602)A

UNIVERSITY OF HEIDELBERG

Centre for Molecular Biology Heidelberg (ZMBH

POSTDOCTORAL POSITION

Human molecular tumour genetics

Applications are invited for a two year postdoctoral positi
to participate in the ongoing molecular analysis of chrom
some 11p13 The focus of the work will be the identification
genes at or near the translocation breakpoint (11,14) (p13,1
in childhood T-ALL The successful candidate should have
strong background in cell biology, immunology and prote
chemistry Salary will be according to german BAT regulation

Please send full CV and the names of two referees to **Dr Royer-Pokora, Institut fur Humangenetik, Im Neuenheim Feld 328, 6900 Heidelberg, FRG,** by December 31, 1989

(W6747)A

MOLECULAR ENDOCRINOLOGY OF HAIR GROWTH

University of Glasgow

Dermatology Department

An immediate vacancy exists for a creative postdoctoral biochemist, molecular biologist in a new research group studying mechanisms of steroid hormone action in cells cultured from human hair follicles Appointment on scale 1A will be initially for one year, renewable for up to three years Starting salary up to £13,527 per annum

Application to **Dr M B Hodgins, Dermatology Department, Glasgow University, Anderson College Building, 56 Dumbarton Road, Glasgow, G11 6NU** (2130)A

UNIVERSITY OF HONG KONG

CLINICAL PATHOLOGIST

(Re-advertisement)

Applications are invited for the post of Clinical Pathologist in the Immunology Section of the Hospital Pathology Services, Department of Pathology Applicants should be medically qualified and post-registration experience in clinical medicine would be an advantage

Annual salary (superannuable) is on a 13-point scale HK\$219,120–446,040 (approx £17,810–36,260, sterling equivalent as at November 2, 1989) Starting salary will depend on qualifications and experience At current rates, salaries tax will not exceed 15% of gross income Children's education allowances, leave, and medical benefits are provided, housing or tenancy allowances are also provided in most cases at a charge of 7½% of salary

Further particulars and application forms may be obtained from Appointments (37199), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, UK, or from the Appointments Unit, Registry, University of Hong Kong, Hong Kong, (Fax (852) 5-85852549) Closes 13 January 1990

the widest international selection of jobs
in science — EVERY WEEK

AMERICAN CANCER SOCIETY
BASIC CANCER RESEARCH EMINENT SCHOLAR CHAIR
UNIVERSITY OF FLORIDA
(Edward R Koger Professorship)

Applications are invited for candidates to fill a faculty professorship in Basic Cancer Research, funded through an Eminent Scholar Chair sponsored by the American Cancer Society The candidate should have demonstrated a strong commitment to academic medicine Candidates must hold an Ph D , M D , or both, and have an accomplished research record in the investigation of fundamental processes of neoplasia A highly interactive individual would be desirable to take advantage of the research collegiality available at the University of Florida The scholar could be appointed in a basic science department or jointly with a clinical department Salary is negotiable and will be based on credentials Deadline for receipt of applications is January 15, 1990

Candidates for this position should be nominated or they should submit a letter of application stating teaching and research goals, and include a curriculum vitae and at least three names of reference to **Edward M Copeland, III, M D , Chairman of Professorship Search Committee, Department of Surgery, Box J-286, JHMHC, Gainesville, FL 32610**

The University of Florida is an equal opportunity, affirmative action employer (NW4634)A

UNIVERSITY OF CAMBRIDGE
Department of Applied Mathematics and Theoretical Physics
Silver Street, Cambridge, England CB3 9EW

Post Doctoral Positions in Gravitation and Cosmology

The Cambridge Relativity Group wishes to appoint a SERC supported Research Assistant with effect from 1 October 1990, for two years initially with the possibility of reappointment for one further year

The position will be in Cosmology or Quantum Gravity including string theory

Those interested should send a curriculum vitae and publications list to arrive no later than 15 December 1989 They should also arrange for at least two letters of recommendation from someone familiar with their work to arrive by the same date

Salary £10,458-£13,527 p a depending on age (2140)A

BIOCHEMIST POSTDOCTORAL POSITION

Study bacterial glycoproteins and the *Bacillus thuringiensis* insecticidal toxin Experience in HPLC and oligosaccharide characterization highly desirable Requires Ph D in Biochemistry or related area Salary $24,000 Two years expected duration Submit curriculum vitae and three references by Jan 2, 1990 to **Dr Kenneth W Nickerson, Biological Sciences, University of Nebraska-Lincoln, Lincoln, NE 68588-0118** AA/EOE

(NW4628)A

SIMON FRASER UNIVERSITY
CHAIR OF THE DEPARTMENT OF BIOLOGICAL SCIENCES

Applications and nominations are sought for the position of Chair of the Department of Biological Sciences at Simon Fraser University The Department has 35 faculty members whose teaching and research interests cover all the modern areas of Biological Sciences There is a graduate enrolment of some 160 students, and external research grant support in 1988/89 was $2 4 million

A Departmental Chair appointment is for up to five years and is renewable, the salary is negotiable The appointment would normally carry tenure Candidates should have an excellent record in research and a demonstrated ability as an academic leader

Applications or nominations should be forwarded, by January 15, 1990, to the **Dean of Science, Simon Fraser University, Burnaby, B C V5A 1S6**

This advertisement is directed to people who are eligible for employment in Canada at the time of application S F U offers equal employment opportunities to qualified applicants (NW4626)A

WESSEX REGIONAL CYTOGENETICS UNIT

SENIOR GRADE CYTOGENETICIST

A position for a Senior Cytogeneticist has become vacant in the above Unit The successful candidate will be expected to take considerable responsibility for the running of one of the three cytogenetic sections, in teaching junior members of staff and be prepared to rotate through all cytogenetic sections of the Unit Applicants will be expected to have the Diploma in Clinical Cytogenetics from the Royal College of Pathologists and to be fully conversant with all aspects of blood, solid tissue and prenatal cytogenetics Experience in leukaemia cytogenetics would also be an advantage

The Unit is comprised of a large diagnostic cytogenetic section and a well established molecular diagnostic section It actively pursues a number of research projects at the interface of cytogenetics and molecular genetics Salary scale £11,778 to £15,394

Enquiries to Dr Patricia Jacobs or Dr Nina Gregson — Tel (0722) 336212 ext 669 For an application form please WRITE to the **Personnel Department, Odstock Hospital, Salisbury, Wilts SP2 8BJ** Closing Date 15th December 1989 (2153)A

DEPARTMENT OF BIOCHEMISTRY

UNIVERSITY OF BRISTOL

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a three-year appointment funded by the MRC The project involves the identification and characterisation of intramolecular signals required for faithful sorting/targetting/retention of integral membrane proteins specific to the trans Golgi network (TGN) Candidates should have experience in molecular and/or cell biology techniques However, lack of relevant experience should not discourage potential applicants The post is available from 1 1 90 on salary scale £12,879-£13,527 per annum

Informal enquiries can be made to Dr G Banting on Bristol (0272) 303030 ext 4915

For further details telephone Bristol 303136 (ansaphone after 5 00 p m) or write to the **Personnel Office, Senate House, Bristol BS8 1TH** Please quote reference A862

An equal opportunities employer

(2120)A

POSTDOCTORAL/ASSOCIATE RESEARCH SCIENTIST

positions available in the Department of Pharmacology at Yale University School of Medicine to study (1) mechanisms of action of drugs on hypoxic tumour cells with emphasis on the reductive activation of bioreductive alkylating agents, and (2) mechanism of drug induced differentiation of neoplastic cells Ph D required and experience in biochemistry and/or pharmacology desired Deadline for receipt of applications is January 31, 1990 Send curriculum vitae and three letters of reference to **Dr Alan C Sartorelli, Director, Comprehensive Cancer Center, Yale University School of Medicine, 333 Cedar Street, New Haven, Connecticut 06510**

Yale University is an Equal Opportunity/Affirmative Action Employer The Department of Pharmacology encourages applications from Women and Minority Group members (NW4622)A

UNIVERSITY OF OXFORD

DYSON PERRINS LABORATORY

CLONING OF ANTIBIOTIC BIOSYNTHETIC GENES

Applications are invited for an SERC funded postdoctoral research postion in the area of antibiotic biosynthesis in *Streptomyces*, The post is to start as soon as possible Salary will be in the RA1A range, £10458 to £12381, starting point depending on age and qualifications

Applicants should send a c v and ask two referees to write to **Dr A J Pratt, Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY** Oxford University is an equal opportunity employer (2157)A

UNIVERSITY OF NOTTINGHAM

PROFESSORIAL UNIT OF RESPIRATORY MEDICINE

Post-doctoral Research Worker required for an 18-month period with the possibility of extension The work is funded by the Cystic Fibrosis Research Trust and involves the development of micro-assay techniques for the 35 measurement of inflammatory factors including neutrophil granule products and tumour necrosis factor These methods will be applied to infants and children with cystic fibrosis in an attempt to identify independant markers of disease activity Experience with immuno-assay (ELISA or RIA) and of cell handling methods would be useful but not essential Salary on the Grade 1A scale from £10,458 per annum depending on age and experience

Enquiries to **Dr Dennis Shale, Respiratory Medicine Unit, City Hospital, Hucknall Road, Nottingham NG5 1PB or tele phone 0602 691169 ext 45781** (2123)A

UNIVERSITY OF DURHAM

DEPARTMENT OF ARCHAEOLOGY

IMAGING ARCHAEOLOGICAL STRUCTURES BY ELECTRICAL RESISTIVITY TOMOGRAPHY

(Re-advertisement)

Applications are invited for a Postdoctoral Research Assistant in Imaging Archaeological Structures by Electrical Resistivity Tomography for a research project funded by SERC in conjunction with Geoscan Research

Geophysical surveys now play a crucial role in archaeological conservation, excavation planning and resource assessment Existing techniques generally provide only 2-D area maps over buried features with minimal depth information This project will transfer recent developments in medical imaging technology to archaeology by developing a novel electrical resistivity tomography system capable of resolving archaeological structures in 3-D The research will involve theoretical studies, numerical simulation, laboratory and field experiments with interaction between the archaeological, medical and physical sciences Suitable candidates will have a strong background in applied mathematics, physics, geophysics or related fields

The appointment is tenable for three years from as soon as possible and the initial salary will be on the Research Staff Scale Grade 1A (£10,458-£12,381 p a) Informal enquiries may be made to Dr M Noel, Department of Archaeology, (091) 374 3631

Further particulars (quoting reference SS/AS/89 04) may be obtained from the Registrar and Secretary (Faculty of Social Sciences), University of Durham, Old Shire Hall, Old Elvet, Durham DH1 3HP, telephone (091) 374 2995, to whom applications (three copies), including the names and addresses of three referees, should be sent not later than Wednesday 6 December 1989 Previous candidates need NOT apply (2074)A

平成2年度 基礎科学特別研究員制度の案内について

科学技術庁と理化学研究所とは 連携して我が国の基礎研究を強力に推進するため 平成元年度に引続き平成２年度の基礎科学特別研究員の募集を計画しています。斬新な研究課題を自主的に遂行できる若い在外の我が国研究者の応募を期待します。

1 採用予定人員／25名

2 受 入 機 関／理化学研究所

3 募 集 分 野／物理学 化学 生物学 工学の各分野で 理化学研究所で実施可能な研究。

4 対　象　者／原則として平成２年４月１日現在35才未満の健康な者で 博士号取得者
又はこれと同等の研究能力を有すると認められる者。

5 待　遇　等／(但し 平成元年度実績)
1 謝 金 月額 475千円程度(社会保険料 税込)
2 通勤費 実費 (上限26千円／月)
3 住宅費 家賃の一部支給
以上のほか 研究費として1 360千円／年程度。

6 契約予定期間／通算３年間を限度とし 毎年度所要の評価により契約更新。

7 応募の意向のある方は12月15日金までに下記にお問い合わせ下さい。

FELLOWSHIPS

LISTER INSTITUTE RESEARCH FELLOWSHIPS

30 October, 1989

Applications are invited for Lister Institute Research Fellowships, of which up to five will be available from about October 1990, each tenable for five years An extension would be considered in appropriate circumstances, subject to satisfactory review Candidates must be post-doctoral in the bio-medical field and aged under 34 years, with evidence of independent research, including at least two years' post-doctoral research, and with an interest in a scientific aspect of preventive medicine *Special arrangements will be considered for those clinicians who are required to undertake further training for accreditation in their speciality* A permanent post temporarily vacated by the Fellow must be protected by his/her employing institution which will be expected to appoint a temporary replacement during the period of the Fellowship The salary, payable by the employing institution and reimbursed by the Institute, will normally be on University clinical or non-clinical scales, with London Weighting if appropriate, plus USS and N I contributions A generous allowance for consumables and minor equipment is also payable

Note In exceptional circumstances, as for example where there have been career breaks on family or other grounds, the Institute would consider electing Fellows aged up to 40 years Personal details supporting the claims of such candidates must be provided in writing The Institute will then give a decision as to whether or not the candidates may proceed to submit a full application for a Fellowship

Application forms and further particulars may be obtained from — **The Secretary, Ref N/I, The Lister Institute of Preventive Medicine, Brockley Hill, Stanmore, Middlesex HA7 4JD** to whom completed forms must be returned not later than 26 January, 1990 (2134)E

The Wellcome Trust

Advanced Training Fellowships in Toxicology

The Wellcome Trustees wish to strengthen the quality of toxicological research in universities In particular, they hope to promote the career development of men and women who wish to pursue research on toxicological problems in departments not only of pharmacology and toxicology, but also departments of physiology and other related subjects

The Trustees therefore announce a limited number of advanced training fellowships in toxicology Applications are invited from medical and post doctoral scientific graduates who have worked in universities, institutes or hospitals in the United Kingdom or the Republic of Ireland for at least the past three years, or who did so before taking up an appointment overseas and who now wish to return from abroad These awards, which are tenable for up to three years, are intended for candidates who are able to provide evidence of their ability to undertake original research, and who wish to extend their research experience The fellowship will be held in an appropriate department in a British or Republic of Ireland university or research institute, but part of the fellow s time may be spent in an appropriate department overseas

Applications will be particularly welcome from men and women whose previous experience has not been in toxicology, but who have been trained in one of the related scientific disciplines, and who now wish to develop a career in toxicology Candidates are welcome to discuss their plans with the scientific staff of the physiology and pharmacology section of the Trust

Candidates should preferably be less than 32 years of age for science graduates and 34 for medical graduates However, equal consideration will be given to those over this age where their career has been affected either by a late start, or by interruption for personal or family reasons Applicants must be nominated by the head of department in the university or institute in which the candidate proposes to work Salary, according to age and experience, will be based on the Trust's own fellowship scale which is related to the university lecturer scale

Application forms can be obtained from
The Grants Section (T/F), The Wellcome Trust,
1 Park Square West, London NW1 4LJ Tel 01-486 4902

Applications must be returned by 23rd February 1990
Late applications will not be considered

(2127)E

Faculty of Science

Postdoctoral Research Fellow in Cellular Mechanisms of Memory

Applications are invited from candidates with a good background in neurochemical techniques for a SERC-funded postdoctoral fellowship in cellular mechanisms of memory The research will be carried out in the Biology Department at the Open University campus, Milton Keynes, under the supervision of Professor Steven Rose and Dr Michael Steward of the University's Brain and Behaviour Research Group The project concerns the role of neurotransmitter release, protein phosphorylation and receptor-second messenger ion channel coupling in memory consolidation processes in the young chick

Applicants should have a PhD degree in a relevant subject area

The post is available immediately for a period of three years Salary will be either on the Grade 1A scale for Research and Analogous Staff (£10,458–£16,665 p a), or the Grade II scale (£15,372–£20,469 p a), according to age and experience

Application forms and further particulars are available from **Ann Hall (7107/), Faculty of Science, The Open University, Walton Hall, Milton Keynes, MK7 6AA**, or telephone Milton Keynes (0908) 655938 there is a 24-hour answering service on 653868

Candidates may also wish to contact Professor Rose on (0908) 652125 to discuss the project

Closing date for applications 13 December

Equal Opportunity is University Policy (2176)E

The Open University

POLYTECHNIC SOUTH WEST
Faculty of Science
Department of Environmental Sciences
Plymouth

Research Fellowship in Organic Chemistry

Salary within the range £10,575 to £13,914 per annum (starting point dependent upon qualifications and experience)

Applications are invited for a Research Fellowship to undertake a 3 year project under the supervision of Dr Steven Rowland, entitled "A quantitative and qualitative characterisation of organic matter from a variety of recent sedimentary environments" The project will involve a multi-method approach to the characterisation of humic substances and "protokerogen" and is funded by a major international oil company

Applicants should possess, or have submitted, a PhD in some aspects of organic geochemistry and preferably have experience in pyrolysis techniques The appointment will commence as soon as is mutually agreeable after 1st January 1990

Application forms, to be returned by Friday 15th December 1989, and further details are available from the Personnel Department, Polytechnic South West, Drake Circus, Plymouth PL4 8AA, or by telephoning (0752) 232167 (2166)E

Sabbatical and Postdoctoral Fellowships

Keratinocyte Biology

State University of New York
at Stony Brook
Department of Oral Biology
and Pathology
School of Dental Medicine

The aim of these fellowships is to foster research in keratinocyte biology in areas relevant to epithelial gene therapy Emphasis is placed on secretory activity of epidermal keratinocytes although other topics of research will be considered Stipend level and duration is negotiable At the sabbatical level, stipend is intended to supplement an existing salary

Send résumé, brief summary of research interests, copies of recent publications and names of references to **Dr Lorne B Taichman, Professor, Department of Oral Biology and Pathology, School of Dental Medicine, SUNY Stony Brook, Stony Brook, NY 11794-8702** (NW4639)E

FELLOWSHIP

LABORATORY OF NEUROSCIENCES

The Laboratory of Neurosciences in the National Institute on Aging, National Institutes of Health, Public Health Service, invites applications for a Fellowship position to study the neurobiology of genes from human chromosome 21 and mouse chromosome 16 by the use of transfected cultured neurons and the development of transgenic mice Current laboratory projects include the effects of human trisomy 21 (Down Syndrome) and mouse trisomy 16 (a model of trisomy 21) or ionic currents, gene expression, lipid metabolism and receptor-second messenger signalling Candidates should have experience in molecular biology and interest in the isolation of genes and chromosomal segments with the aim of determining the role of specific genes in aneuploid-related neurophysiological abnormalities Available from late 1989 - early 1990 Position is located in Bethesda, Maryland and salary is commensurate with qualifications Send resume and the names of three references to

Stanley I Rapoport, M D
Chief, Laboratory of Neurosciences
National Institute on Aging
Bldg 10, Room 6C-103
9000 Rockville Pike
Bethesda, Maryland 20892
U S A

NIH IS AN EQUAL OPPORTUNITY EMPLOYER

(NW4532)E

Ciba-Geigy Biotechnologie Department Basel, Switzerland

A Postdoctoral Fellowship Position

is immediately available for a period of up to three years at the Biotechnologie Department of Ciba-Geigy to study the molecular interactions between a protein and its receptor The project will involve both genetic engineering of the cloned ligand protein and immunological epitope mapping of the binding domain to the receptor

Applicants must have a good working knowledge of molecular biology techniques, expertise in immunological and biochemical characterization of ligand-receptor complexes

The successful candidate is encouraged to establish contacts with the academic community This position offers good possibilities to develop own ideas in a stimulating research environment Publication of results is strongly encouraged.

Applications, including a curriculum vitae, a description of current research interests and the names and addresses of three referees should be forwarded under ref "Nature 2731" to Mr H. Schmid, CIBA-GEIGY Limited, Personnel Department, P O Box, 4002, Basle, Switzerland

CIBA–GEIGY

Offen für Ihre Einstellung. (W6733)E

THE UNIVERSITY OF BIRMINGHAM
SCHOOL OF BIOLOGICAL SCIENCES
M.R.C. POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a three year Postdoctoral Research Fellowship in the laboratory of Dr Chris Thomas to study the molecular biology of the processes which lead to partitioning of bacterial plasmids to daughter cells prior to cell division The work will involve a range of techniques in molecular genetics and protein biochemistry, experience in these areas is highly desirable Salary will be in the Research Fellow IA range (£10,458-£16,665) and the post is tenable from 1 January 1990

Informal enquiries to Dr Chris Thomas by phone (021 414 5903)

Further particulars and application forms can be obtained from the **Director of Staffing Services, the University of Birmingham, Edgbaston, Birmingham B15 2TT** (telephone 021 414 6483 — answerphone) to whom applications (3 copies) should be returned by 15th December quoting reference number 13009

AN EQUAL OPPORTUNITIES EMPLOYER

(2168)E

RESEARCH FELLOWSHIPS IN THE ENVIRONMENTAL SCIENCE

Applications are invited from outstanding, young research workers for a limited number of Post-Doctoral and Advanced Research Fellowships, located at various British Universities, Polytechnics and Research Institutes

All candidates should be able to show an aptitud for original and independent research and must posses a PhD Advanced Fellowship applicants should also hav relevant post-doctoral experience and are expected to b of the calibre of new blood lecturers

Fellowships will be tenable for a period of up to 5 years in the first instance Salary will be in the range **£10,458** to **£16,665** (as at 1 4 89)

Proposals for Fellowships, together with application forms RF1 and RF2, are available from the Registrar's Offices and should be submitted to NERC by 15th December 1989

For further details please contact Dr Colin Vincent, Higher Education Section, NERC, Polaris House, North Star Avenue, Swindon SN2 1EU or telephone Swindon (0793) 411512

— the professionals' choice

INSTITUTE OF PSYCHIATRY

(University of London)

Department of Psychology

Research Studentships in Psychology and Neuroscience

Applications are invited from students wishing to read for a doctorate The Department has facilities for research in a wide selection of fields, ranging from studies of the neuroanatomical, neurochemical and molecular bases of behaviour in animals to the clinical investigation of abnormal human behaviour in a variety of psychiatric and neurological disorders Wherever possible fundamental and clinical research programmes are closely co-ordinated There is extensive collaboration with other Departments (eg Neuroscience, Neuropathology, Psychiatry, Neurology) in the Institute of Psychiatry Graduate students currently in the Department are supported by Studentships from a variety of sources, including the pharmaceutical industry (Glaxo, Shering) *Awards are made on a competitive basis* Applicants from the UK should have or expect to gain at least an Upper Second Class Honours degree in psychology or neighbouring fields within the biological, social or medical sciences Applicants from overseas should be of equivalent standard with a good command of English

Applications should be sent as soon as possible (and not later than 16 February 1990) to **Mrs Shirley Chumbley, Department of Psychology, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF** (from whom application forms can be obtained) (2141)F

SCHOOL OF PHARMACY UNIVERSITY OF LONDON

UNIVERSITY/INDUSTRY CENTRE FOR PHARMACEUTICAL RESEARCH

Postgraduate Studentships in Pharmaceutical Sciences

Applications from students trained in chemistry, biochemistry, pharmacy or pharmacology are invited for three Ph D studentships in any of the following areas

(1) Receptor and Ion-Channel Biochemistry
(2) Glycerol and Sphingolipid Biosynthesis and Degradation
(3) Synthetic and/or Biological Studies of novel transmembrane delivery
(4) CNS, Anti-inflammatory and Anaesthetic drug design and synthesis

The Centre is equipped for all aspects of the above research programmes Stipends will be in the range of £4,600 to £6,250 depending upon the source of funding and the experience of the candidates suitability Applications should be sent to **Professor William A Gibbons, School of Pharmacy, 29-39 Brunswick Square, London WC1N 1AX** from *whom further particulars may be obtained* (2142)F

Prize Studentships/ Research Scholarships

DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF DUNDEE

Able candidates wishing to study for the degree of Ph D are sought for nomination to the above positions The Department is one of the most successful *and highly rated in the UK* for biochemistry research and is very well equipped and funded In addition to the outstanding research facilities and working environment, access to outdoor recreational facilities is unrivalled and accommodation/living expenses are among the lowest in Britain Research projects are available in a wide range of areas including cell biology, molecular genetics, protein phosphorylation, intracellular signalling and cell cycle control

Applications, including a full curriculum vitae and the names and addresses of two referees should be sent as soon as possible to **Dr M J R Stark, Department of Biochemistry, The University, Dundee DD1 4HN** (tel 0382–23181 ext 4250) Prospective applicants are requested to phone Dr Stark immediately for a copy of the Departmental brochure and information about the Tayside area Travel and overnight accommodation will be provided for applicants invited for interview (2178)F

COURSES & CONFERENCES / WORKSHOPS

Natural Environment Research Council

NATO ASI Series

MOLECULAR TECHNIQUES IN TAXONOMY

UEA NORWICH

JOHN INNES INSTITUTE

AFRC Institute of Plant Science Research

NATO Advanced Studies Institute
Norwich UK 9–20 July 1990

This **tutorial course** aims to bring together some 20 international authorities and 70 young researchers to discuss and learn about this exciting interface Lectures, seminars and laboratory practicals will use molecular and computer methods for systematic studies

Topics will include — Taxonomic concepts, DNA hybridization, PCR and DNA sequencing, mtDNA, rDNA, scDNA, RFLPs, Sequence databases, Phylogenies, Computer programmes, Non-DNA techniques, Rapid diagnosis Applications to microbes, plants, insects and vertebrates — in Agriculture, Conservation, Medicine and Evolution

Speakers will include — Humphrey Greenwood (British Museum), James Murray (Virginia), Hampton Carson (Hawaii), Jean David (Gif), Eleftherios Zouros (Crete), Christine Simon (Hawaii), Jeffrey Powell (Yale), Dieter Sperlich (Tubingen), Robert Cedergren (Montreal), Jeffrey Doyle (Cornell), Michel Solignac (Gif), Martin Kreitman (Princeton), Antonio Fontdevilla (Barcelona), Bryan Clarke (Nottingham), David Swoffard (Champaign), Peter Young (Norwich), and others

The Location is the University of East Anglia which, along with several Research Institutes, is set in parkland on the edge of the ancient City of Norwich

Applications to Professor Godfrey Hewitt University of East Anglia, Norwich NR4 7TJ before **31 January 1990** should include a CV with research interests — molecular or taxonomic expertise is not a prerequisite Full accommodation fee is £390, please explain in your application if you could not attend without a subsidy Some NATO countries give grants for these ASIs (2172)C

FIRST ANNOUNCEMENT

ORAL IMMUNISATIO
USING RECOMBINAN
BACTERIA

June, 6-7, 1990, Munich, FR

Speakers include B Askonas, D Clements, J Clark-Curtiss, Curtiss, G Dougan, P Freimu T L Hale, M Levine, J Hol gren, J B Kaper, S Kaufma J J Mekalanos, M Radm P Reeves, M H V Regenmort W S Robinson, J C Sad J Sanchez, S Snapper, B A Stocker, R Weiss

Organisers M Hofnung, Ins tut Pasteur, Paris, F Schod Max-Planck-Institut fur Bi chemie, Martinsreid

Supported by the Walt Schulz Foundation and the C Friedrich v Siemens Foundatio

20 abstracts will be accept for poster presentations Dea line for submission March, 1990

Information and abstract su mission F Schodel, Ma Planck-Institut fur Biochem D-8033 Martinsreid, Tel 8578 3759, Fax (89) 8578 3777 (W6744)C

NATO Advanced Research Workshop
Phytochrome Properties and Biological Action
Chichester, England: July 22–27, 1990

The meeting forms part of the NATO Cell Signalling series and will deal in detail with the mechanisms by which phytochrome regulates plant development Topics to be covered include — Molecular properties of phytochromes, Intracellular location, biogenesis, and turnover of the phytochrome molecule Signal transduction mechanisms Regulation of gene expression by light Evolution and biological function of phytochrome Phytochrome expression in transgenic plants The proceedings of the meeting will be published as part of the NATO ASI series

Those wishing to attend the workshop should write to the conference organiser including a short Curriculum vitae and an abstract (50–100 words) of their proposed contribution Deadline for applications is DECEMBER 31ST 1989

It may be possible to give financial assistance to some selected applicants, especially those from Greece, Portugal and Turkey Scientists from these countries are particularly encouraged to apply

For further information contact the conference organiser, **Dr Brian Thomas, AFRC — IHR, Worthing Road, Littlehampton, West Sussex BN17 6LP U K** Tel 0903-716123 FAX 0903-726780 (2163)V

EMBO Course 1990

Development, regeneration and plasticity of the nervous system — an introductory experimental course

Max-Planck-Institut fur Entwicklungsbiologie Tubingen

February 18 – March 3, 1990

Deadline for application January 10, 1990

15 participants

Topics

Plasticity of synaptic connections in the central nervous system Genes involved in neurogenesis during embryonic development of Drosophila Retinogenesis in vitro — Axonal growth in retina organ culture — Cell adhesion molecules In vitro studies — Axonal growth and guidance Ocular-dominance plasticity in developing kitten visual cortex An analysis of cell lineage in the rat cerebral cortex An analysis of cell lineage in the rat cerebral cortex using a retroviral vector Shifting connections in the retinotectal system Influences of peripheral nerve-derived factors on CNS regeneration Experimentally induced neural projection during embryogenesis of the chick visual system

Applicants should provide a brief c v and reasons for their wish to participate (not more than 1 page)

Applications should be sent to **Drs F Bonhoeffer & U Schwarz, MPI fur Entwicklungsbiologie, Spemannstr 35, D-7400 Tubingen, FRG,** Tel 07071/601 340 or 601 413 Fax 07071/601 300 (W6743)C

United Nations Industrial Development Organization

INTERNATIONAL CENTRE FOR GENETIC ENGINEERING AND BIOTECHNOLOGY (ICGEB)

MOLECULAR AND GENETIC APPROACHES TO PLANT STRESS

15–17 February 1990, New Delhi, India

Invited speakers and moderators include.

M Bhattacharyya (St Louis, USA), F R Bidinger (ICRISAT, India), C -W Chi (Shanghai, PR China), Y -L Fan (Beijing, PR China), A Gatehouse (Durham, UK), T K Hodges (West Lafayette, USA), R Hull (Norwich, UK), R Johnson (Pullman, USA), K Kloppstech (Hannover, FRG), J Leach (Manhattan, USA), J Manners (Brisbane, Australia), J Mullet (College Station, USA), K S Nwanze (ICRISAT, India), H Pakrasi (St Louis, USA), J Peacock (ICRISAT, India), R S Rana (New Delhi, India), M A Rezaian (Adelaide, Australia), E.A Siddiq (Hyderabad, India)

Sessions will cover

Plant viruses, fungal diseases, pest resistance, insecticidal proteins, plant transformation and regeneration, RFLP analysis, stress-regulated gene expression, genetic variation in pathogens and pasts, heritability of resistance to abiotic stress, herbicide degradation and resistance Two poster sessions will allow participants to present their work

Registration

The Symposium will be held at the Ashok Hotel, New Delhi, with registration on Wednesday, 14th February

Aims

The Symposium will bring together molecular biologists and geneticists concerned with biotic and abiotic stress in plants Lectures and discussions will focus on the use of molecular, cellular and genetic techniques to accelerate the breeding of plants with enhanced stress resistance Since ICGEB has a mandate for research and advanced teaching in genetic engineering and biotechnology for the benefit of developing countries, applications are especially welcome from citizens of these countries A limited number of travel scholarships are available for applicants from ICGEB member countries

Application

The deadline for applications is 14th December 1989 Applications may be made by post or by fax and should include a curriculum vitae, a brief description of research interests, and a fax or telex number for reply The organizers will notify those who have been accepted as soon as possible after the deadline The total number of participants will be limited to about 100 Applications should be addressed to **Mr. G Chatterjee, Administrative Officer, ICGEB, NII Campus, Shaheed Jeet Singh Marg, New Delhi-110067, India (fax: 91-11-6862316)** Successful applicants will be expected to present a paper (W6453)M

UNIDO

Genetics Short Course

16-27 July 1990

1st Annual Short Course in Medical & Experimental Mammalian ienetics Conducted by Johns Hopkins University and The Jackson aboratory at Bar Harbor, Maine Morning and evening lectures overing the field are supplemented by workshops, tutorials, and emonstrations Inquiries, applications to

H Roderick, Ph D, c/o Training & Education Office The Jackson boratory, 600 Main St, Bar Harbor, ME 04609, or V A McKusick, .D, 1007 Blalock, Johns Hopkins Hospital, Baltimore, MD 21205

(W6751)C

THE NEW YORK ACADEMY OF SCIENCES

Conference on:

Central and Peripheral Significance of Neuropeptide Y and Its Related Peptides

Baltimore Hyatt Inner Harbor, Baltimore, Maryland

April 2-4, 1990

The isolation and characterization of Neuropeptide Y (NPY) in the early 1980's has stimulated a number of studies into the molecular biology, biochemistry and physiology of this neuropeptide and its related peptides The ubiquity of NPY in the brain and periphery suggest that this neuropeptide is of physiological importance in homeostatic regulatory mechanisms of a number of species This conference will provide a forum for investigators to exchange ideas on the structural, functional and anatomical aspects of NPY with the hope of elucidating strategies for the development of selective ligands for the NPY receptors which could potentially unravel the biological and clinical significance of NPY in the nervous and cardiovascular systems

There will be contributed poster sessions in conjunction with this conference *Posters are encouraged* The deadline for submission of abstracts is *February 1, 1990* The entire abstract, including title, author(s), and affiliations, must be typed single-spaced and contained within a rectangle that measures 5 × 4 and 3/6 inches (W × L) Abstracts should be sent to one of the chairpersons (Abstract form is not necessary)

CONFERENCE CHAIRPERSONS

Dr Janet M Allen, Dept of Medicine, Royal Postgraduate Medical School, London W12 0NN, England

Dr James Koenig, Laboratory of Neuroendocrinology, Massachusetts General Hospital, 149 Thirteenth Street, Charlestown, MA 02129, USA

For further information contact **Conference Dept, The New York Academy of Sciences, 2 East 63rd Street, New York, NY 10021, USA TEL 212-838-0230, FAX 212-888-2894** (NW4637)C

COURSES & CONFERENCES

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION
PRACTICAL COURSE

"GENETIC MANIPULATION OF *STREPTOMYCES*"

JOHN INNES INSTITUTE, NORWICH, ENGLAND
14–28 July 1990

The course will include gene cloning, protoplast fusion, mating, phages and plasmids Instructors M J Bibb, C J Bruton, M J Buttner, K F Chater, D A Hopwood, H M Kieser, T Kieser, R E Melton and J White

Further particulars and application forms from **Professor D A Hopwood, John Innes Institute, Colney Lane, Norwich NR4 7UH, England** (Deadline for applications 1 April 1990) (2159)A

HEART RESEARCH

The Coronary Artery Disease Research Association supports investigations into the non-invasive, presymptomatic diagnosis of cardiovascular disease, a fuller understanding of atherogenesis and the evaluation of measures to arrest/protect against the disease process with the aim of preventing premature death and disability

The charity has a continuing interest in the cardiological applications of magnetic resonance techniques with particular emphasis upon ischaemic heart disease

Applications for the support of research consonant with the charity's aims are now invited Application forms are available from the address below and should be completed for return **no later than 26th January 1990**

Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer.

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

Take out a personal subscription to Nature today at HALF PRICE.

MERMAID

Isolate OligoMER & Low MW DNA from Gels or Solution

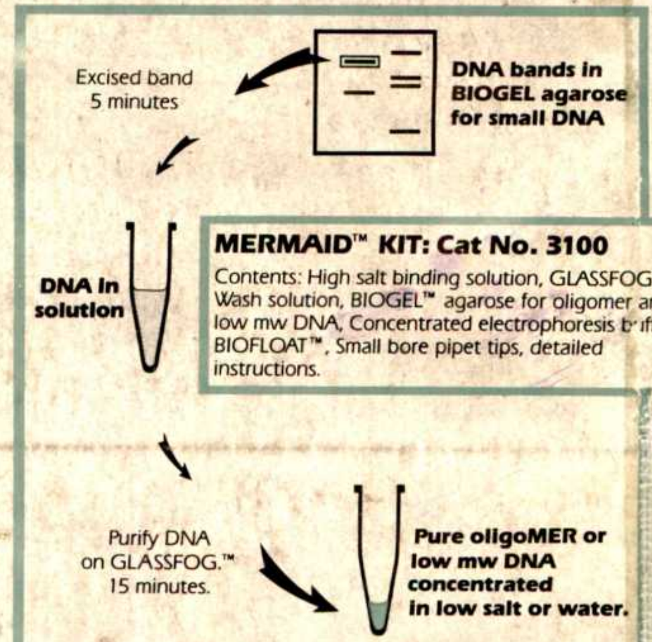
The **MER**MAID™ Kit

A new "Quickit" from **BIO 101** that lets you:

REMOVE AND PURIFY DNA OLIGOMERS FROM AGAROSE GELS FAST... 20 minutes from gel-band to purified DNA in water or TE.

RAPID REMOVAL AND PURIFICATION OF PROBES AND PRIMERS FROM HIGH SALT OR GELS... 15-20 minutes without columns, alcohol precipitations or organic extractions.

WORKS FOR DOUBLE AND SINGLE-STRANDED DNA OLIGOMERS... from as short as 10 bp to longer than 1000bp.



MERMAID™ KIT: Cat No. 3100

Contents: High salt binding solution, GLASSFOG™ Wash solution, BIOGEL™ agarose for oligomer an low mw DNA, Concentrated electrophoresis buf BIOFLOAT™, Small bore pipet tips, detailed instructions.

To order **MERMAID** Kit or for further information contact BIO 101 in the U.S. or nearest distributor.

FROM START TO FINISH ...

As the race to bring biopharmaceutical products to market quickens, companies are closely examining their allocation of resources. Many have found that, whether they are developing recombinant proteins or monoclonal antibodies, there is good reason to use CELLTECH's experience in this field to increase the quality and certainty of their development programme and final manufactured product.

CELLTECH already provides many of the world's major pharmaceutical and biotech companies with specialist development and manufacturing services. These include:

- Mammalian and microbial cell line development
- Biopharmaceutical process and assay development
- Industrial and pilot scale manufacture of clinical grade biopharmaceuticals

With licensed products already being manufactured and further product licence applications under way, CELLTECH's track record of providing quality biopharmaceutical development services is outstanding.

CELLTECH

Our **dedicated, industrial-** **manufacturing facilities,** util airlift fermenters, give us a capac more than ten kilograms of pr every year. This technolog compatible with hybridomas recombinant mammalian cell lin both of which are routinely grov serum-free media to make therap grade product.

Nowhere is CELLTECH's atte to detail more effectively demonst than in **product assay developmen process validation support**. T activities are essential to the manufa of a consistent product, and bec increasingly important as products r the clinical trial stage. Our valid procedures include the follo studies:

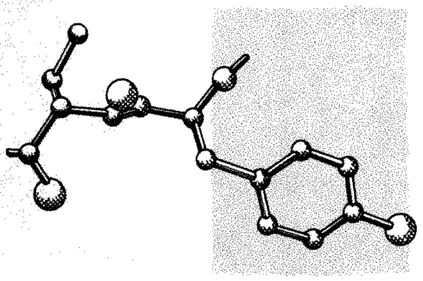
- Clearance of DNA, viruses, et
- Sensitivity of key process param
- Operation of fication colum
- Stability of pr intermediates

All these st require dedicated duct assay dev ment and supp Recent developments at CELLT include highly sensitive as for murine and hamster DNA, assays to demonstrate clearanc

cific medium and host cell derived taminants.

All materials are manufactured under GMP guidelines. Our purpose-lt manufacturing facilities have cessfully passed inspection by regu- ory bodies on both sides of the antic.

omprehensive regulatory aware- and support have been obtained ough our accumu- d experience with horities throughout world. As a result, Regulatory Affairs n can help to ensure cessful regulatory missions for products manufactured ELLTECH.



Biopharmaceutical manufacturing is t of a comprehensive package of ser- es which CELLTECH is able to pro- e to achieve the therapeutic potential our products. Additional **specialist** vices that CELLTECH offers include:

rotein engineering — construction f humanized antibodies

Mammalian expression — development of highly productive CHO or myeloma lines using a proprietary gene amplification system

mmunopurification reagents — development of faster, high performance protein recovery

CELLTECH has a firm financial base; it operates in the services business at a profit. This ensures that CELLTECH will remain a viable company, able to maintain its long-term commitments to biopharmaceutical customers.

As you plan the development, scale up, production, and clinical testing of your new biopharmaceutical, remember that CELLTECH is ready to meet all your needs for recombinant protein and antibody manufacture with proven technology and expertise.

To arrange a time for us to discuss your needs in complete confidence, contact Ian J. Nicholson or Susan J. Dexter at CELLTECH Limited, Riverbend Office Park, 9 Galen Street, Watertown, MA 02172, USA, or call 1-800-552-4934 or 617-923-4310 (Fax: 617-923-6480).

In Europe, contact CELLTECH Limited, 216 Bath Road, Slough, SL1 4EN, Berkshire, England, or phone UK (0753) 34655, International +44 753 34655 (Fax: (0753) 36632).

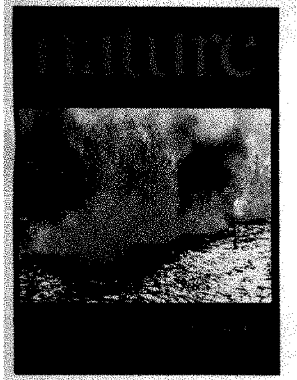
..CELLTECH WORKS FOR YOU



nature

7 December 1989
Vol. 343 Issue no. 6250

◀ Turbulent fountaining of lava above two eruptive fissures near the current site of the vent at Pu'u O'o, Hawaii. Photo by J. Griggs (USGS) in February 1983. A model to account for some of the behaviour patterns displayed by such eruptions is presented on page 665, and discussed in News and Views.

THIS WEEK

Shear rivalry

Rival US and Australian patents on 'gene shear' technology raise the issue of the effect of commercialization on the open discussion of research results, page 609.

Target for HIV

An HIV gene product that plays a part in controlling the activity of the AIDS-inducing virus binds directly to a specific segment of some messenger RNA molecules transcribed from HIV. Page 714.

Glutamate receptor

The expression, cloning and sequencing of a kainate receptor from rat brain provides the first primary structure of a family of receptors believed to play a central role in memory acquisition, page 643. Sequences of kainate binding proteins from frog brain (page 684) and chick cerebellum (page 689) are consistent with their being the binding domain of the functional receptor. See also News and Views page 617.

On the level

A continuous detailed record of sea-level variations over the past 17,000 years has been obtained from studies of coral reefs off Barbados. One of the more surprising findings is that there were two periods of rapid sea-level rise during the last deglaciation. These results give new insight into the relation between ocean circulation and climate change. Pages 637 and 616.

Whipped into shape

Images from X-ray fibre diffraction reveal the arrangement of flagellin subunits within the core of a bacterial flagellum and show that there is a central channel through which the subunits are transported to the distal end of the growing filament. Page 648.

A crucial difference

The 'left-handed' stereoisomer of thalidomide is a powerful and safe tranquilizer; but the 'right-handed' isomer was also present in the drug preparations used in the 1960s, and was responsible for many severe birth defects. An important aim of pharmacology, therefore, is the synthesis of drugs containing only the active enatiomer, and on page 631 Brown and Davies review progress towards chemical synthesis of specific stereoisomers.

Cement relationships

'Cement sickness' due to sulphate attack is afflicting many buildings around the world, but it is often difficult to establish the origin of the sulphate. Sulphur isotope analysis is shown (page 663) to be a useful tool in tracing the source.

RA and development

The three conserved genes for the three types of nuclear retinoic acid receptor are differentially distributed during development of the mouse limb bud, and the timing and pattern of expression of these and the cytoplasmic retinoic acid binding protein suggest how responses to retinoic acid may be regulated during limb morphogenesis. Page 702.

Name dropping

A study of a brain-damaged patient with a selective inability to retrieve proper nouns suggests that these words are represented or accessed in the brain separately as a category distinct from common nouns, page 678.

New old reptile

Fully evolved reptiles existed 340 million years ago — 40 million years earlier than previously thought, page 676.

JANSSEN
and
Amersham
are pleased to announce:

From 1 January 1990 Amersham International plc will be extending their product range by acquiring from **Janssen Biotech NV** a number of high quality immunological detection reagents, for use in electron microscopy, light microscopy and blotting, including:

AuroProbe*One
Ultra small immunogold probes.

- **AuroProbe EM**
Immunogold probes for electron microscopy.
- **AuroProbe LM**
Immunogold probes for light microscopy.
- **AuroProbe BLplus**
Immunogold probes for blotting.

IntenSE*M
For silver enhancement of gold particles in microscopy.

- **IntenSE BL**
For silver enhancement of gold particles in blotting.
- **AuroDye*forte**
For staining protein blots.
- **AuroBeads***
Ready-to-use gold sols for labelling macromolecules.
- **Biotinylated secondary antibodies**

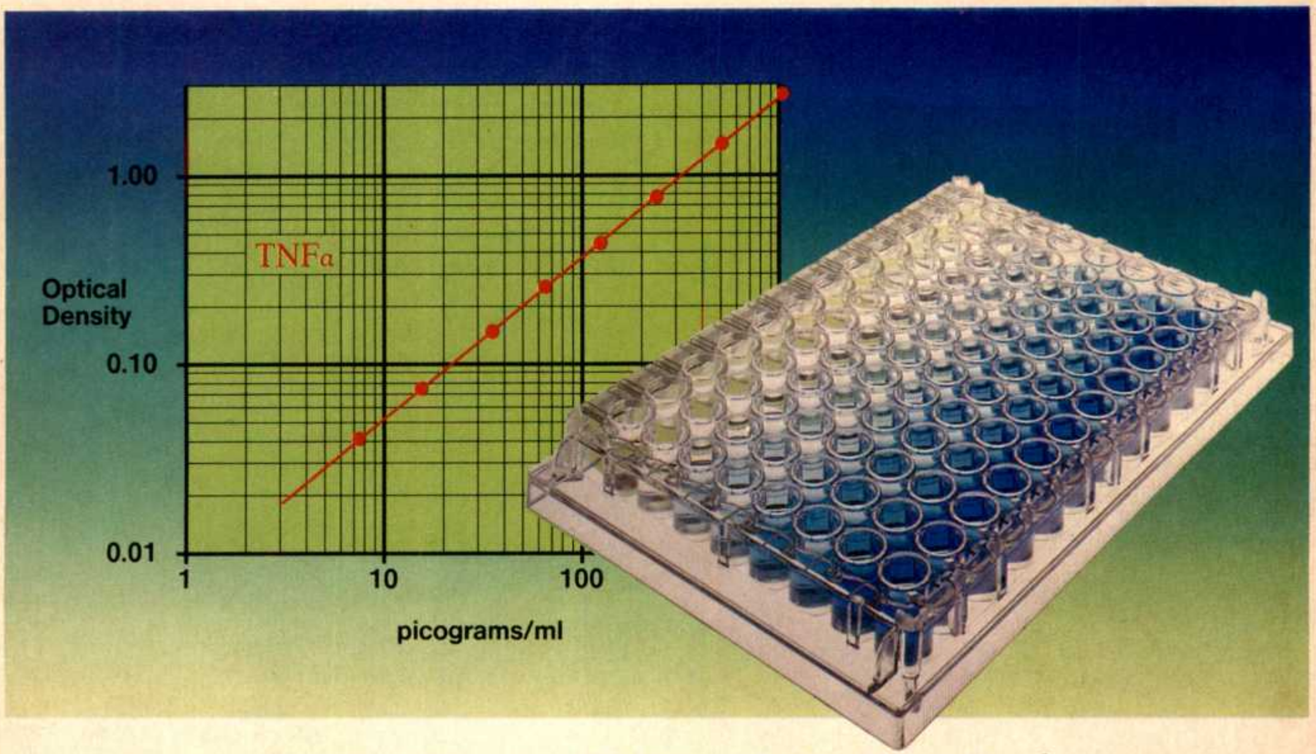
Quantikine™

For the Precise Quantitation of Cytokines.



ELISA Kits for TNF-α, IL-1β*, IL-4*, IL-6

R & D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive:	linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.
Precise:	well-to-well CV <8%
Specific:	results not influenced by the presence of other cytokines.
Accurate:	eliminates the inherent imprecision of bioassays.
Rapid:	simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample... Incubate (2 hours)... Wash... Add Detection Antibody... Incubate (2 hours)... Wash... Develop... Read Results.

HARMACIA LKB BIOTECHNOLOGY

HiLoad™ - the best gels in the best columns.

New HiLoad prepacked columns from Pharmacia LKB are the first choice for preparative purifications in Standard Chromatography.

Quality packed by experts under stringent, optimized conditions, they are characterized by their convenience, reproducibility and simplicity.

Furthermore, we are introducing five outstanding new gels available in HiLoad columns, each giving superb resolution at high flow rates;

- Superdex™ 75 prep grade
- Superdex 200 prep grade for gel filtration
- Q Sepharose® High Performance
- S Sepharose High Performance for ion exchange chromatography
- Phenyl Sepharose High Performance for hydrophobic interaction chromatography.

The broad range of 20 prepacked glass columns offer you fast and reliable results in gel filtration, ion exchange and hydrophobic interaction chromatography. All bring convenience into your laboratory - no measuring, no packing, no waiting. Every HiLoad column gives you high capacity, outstanding results and reproducible performance straight from the box; just equilibrate, add your sample - and you are on your way.

Send for the HiLoad column brochure today to make your first choice!

We help you manage biomolecules.

The Molecular Biology of Immune Diseases and the Immu
..........15 Years of Monoclonal Antibodies

For more than two decades, the Symposia have been the premier forum for applied molecular biology. Please join us once again for a double-barreled program highlighting basic research and commercial application:

Plenary Sessions
MONDAY (morning)
Antigen-Specific Receptors
Fred Alt, Columbia
James P. Allison, UC-Berkeley
Harald von Boehmer, Basel Inst.

MONDAY (evening)
Lynen Lecture*
Philippa Marrack
John W. Kappler
National Jewish Center for Immunology And Respiratory Medicine

TUESDAY (morning)
Distinguished Service Award**
Cesar Milstein

TUESDAY (morning)
Antigen Recognition and Lymphocyte Activation
Jack L. Strominger, Harvard
Richard D. Klausner, NIH
Dennis Y. Loh, Washington University

THURSDAY (morning)
Special Achievement Award***
Wallace Coulter, Coulter Electronics

FRIDAY (morning)
Molecular Mediators of Immune Pathogenesis
Kendall A. Smith, Dartmouth
Thomas Malek, University of Miami
Marian E. Koshland, UC-Berkeley
Eckhard R. Podack, University of Miami
Anthony Cerami; Rockefeller University

Molecular Pathogenic Mechanisms
MONDAY (afternoon)
Diseases of Abnormal Antigen Receptor Formation
Ilan R. Kirsch, NCI-NMOB
Hitoshi Sakano, UC-Berkeley
Terence Rabbitts, MRC

TUESDAY (morning)
Molecular Mechanisms in Autoimmunity
Lawrence Steinman, Stanford
Chella S. David, Mayo Medical School
Bonnie Blomberg, University of Miami

TUESDAY (afternoon)
Disordered Regulation of Lymphocyte Activation
Cox Terhorst, Harvard Medical School
Mark L. Tykocinski, Case Western Reserve
Ira H. Pastan, NIH

THURSDAY (morning)
Genetic Disorders of Surface Molecules
Gerald T. Nepom, Virginia Mason Research Center
Bernard F. Mach, University of Geneva
Yee Hon Chin, University of Miami

THURSDAY (afternoon)
Molecular Mechanisms of Immune-Mediated Tissue Injury
Victor Nussenzweig, New York University
Joan Stein-Streilein, University of Miami
Gilla Kaplan, The Rockefeller University

Biotechnology and the Monoclonal Antibody—The Second 15 Years
MONDAY (afternoon)
Receptors, Immunological Structure, and Pharmaceutical Development
Mark I. Greene, University of Pennsylvania
Donald C. Wiley, Harvard
Jeffrey Greve, Molecular Therapeutics
Eckhard Wimmer, SUNY

TUESDAY (morning)
Manipulating the Monoclonal I
James Larrick, Genelabs
Andreas Pluckthun, Max Planck Institute–* Martinsreid
Jorge Gavilondo-Cowley, Center for Genetic Engineering and Biotechnology–Havana

TUESDAY (afternoon)
Manipulating the Monoclonal II
Ellen S. Vitetta, University of Texas
Peter G. Schultz, UC-Berkeley
Christopher L. Reading, M.D. Anderson Cancer Center
Sherie L. Morrison, UCLA

THURSDAY (morning)
The Biotechnology of Allergy
Kimishige Ishizaka, Johns Hopkins
Kevin W. Moore, DNAX Research Institute
Jean-Pierre Kinet, NIH
Tse-Wen Chang, Tanox Biosystems

THURSDAY (afternoon)
New Directions in Immunogenetics
Ursula Storb, University of Chicago
Tak W. Mak, University of Toronto
Charles J. Epstein, UC-San Francisco

*Lynen Lecture sponsored by GIBCO/BRL, a division of Life Technologies
**Distinguished Service Award sponsored by Elsevier Science Publishers
***Special Achievement Award sponsored by the University of Miami School of Medicine
****Monday morning Plenary Session sponsored by Boehringer Mannheim

Telephone Telefax

I understand that as a paid conference participant, I may attend all sessions and receive all program materials.

Registration fees (Please check the appropriate category and make checks payable to: Miami Bio/Technology Winter Symposia):

1. Symposium Registration $________

Category	Through Dec. 31	After Dec. 31
General registration		
Standard	☐ $395	☐ $420
Academic and Government	☐ $195	☐ $220
Student (see below)	☐ $95	☐ $110
Members of the American Society for Biotechnology		
Standard	☐ $350	☐ $375
Academic and Government	☐ $175	☐ $200

Student registrants: Please have your mentor sign below

Mentor's signature

2. Associate Registration $________
   ☐ Associate $25
   Associates do not attend conference sessions, but may participate in receptions, tours, and other social and recreational activities

Associate name(s)

3. Placement Service $________
   ☐ Employer—$100 ☐ Candidate—$10

Total Registration Fee (sum of 1, 2 & 3) $________

Payment:
☐ Check enclosed (payable in U.S. $ only to Miami Bio/Technology Winter Symposia)

☐ Please bill my credit card. (Credit-card users may telefax this form to the Symposia at (305) 324-5665)
☐ American Express ☐ Visa ☐ Mastercard

Card number Expiration date

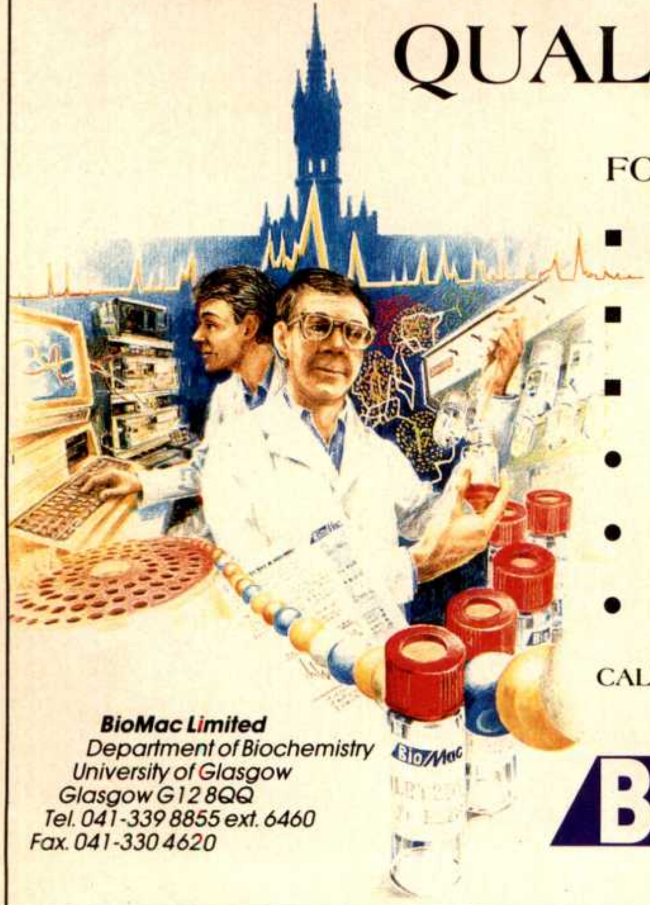
Signature as appears on card

You may pre-register until January 5, 1990. After that date, registrations will be taken on-site.

Sponsor's liability: Should this conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee.

Cancellation policy: All cancellations must be received in writing. Cancellations received on or before December 31 will be subject to a service charge of $25. No refunds will be made after that date. Registrants who are unable to attend may, if they choose, send a substitute.

QUALITY PEPTIDES



FOR ALL YOUR RESEARCH NEEDS

- Low cost Screening Grade Peptides, from £250
- Immunological Grade Peptides for antibody production
- High Purity Peptides for bioassay
- Peptide - Protein Conjugates / Radiolabelled Peptides
- Antibodies / Purification and Analytical Services
- ANF Peptides / Endothelin / G - Protein Antibodies

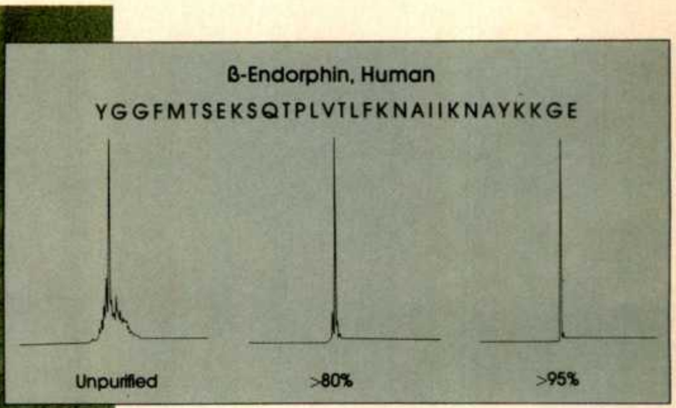
NOW Purified Peptides

MPS specializes in quality, custom peptide synthesis . . . so you don't have to!

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.



COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

		Guaranteed Purity Level	
	Unpurified	>80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

NATURE VOL 342 nature 7 DECEMBER 1989

Tomorrow's conundrum of Europe

Excitement over developments in Eastern Europe should be moderated by a recognition of the chauvinistic dangers that it brings What Europe needs is a moratorium on boundary changes German reunification is best postponed

MALTA's role in European affairs has not been conspicuous since the ending of the Crusades, while the meeting on (rather than, as originally intended, off) the island between Presidents Mikhail Gorbachev and George Bush will not have restored much of its influence That it allowed the two men to smile often and openly in each other's presence is, of course, a plus, the more serious business on arms control planned for next June should now be the more easily carried through Each, no doubt, will now also be more confident that the other is seriously seeking to divert military spending to civil causes — the US administration seems to have seized more eagerly on he chance to cut spending than other members of the North Atlantic Treaty Organization The federal deficit plainly nags like toothache The Soviet deficit, relatively even larger, is for the time being bridged by printing money, no wonder that Gorbachev is pleased that his new friend, Bush, may use his economic influence (but not his cheque-book) to help *perestroika* along Whether that will help during the long winter is another matter

What seems to have foxed the two presidents at the weekend (the weather apart) is the turmoil in Europe They are not alone in that Monolithic regimes in Eastern Europe have been collapsing like dominoes since the Soviet Union let it be known that it would not prevent political change in Poland, now almost a democracy f an impoverished one But that does not mean that Gorbachev has lost control He seems resolute in telling ancient leaders that they cannot stand in the way of history and equally determined that the East European tates should stay within the Warsaw Pact, German nostalgia notwithstanding The benefits? The expectation hat the conservatives in the Soviet Union will understand hat what goes for Eastern Europe also applies to them But the pace of change has left even Gorbachev wanting or a tangible description of what he means by a "common European home" Bush is as perplexed

It is a perplexing business Three years from now, at the nd (not the beginning) of 1992, the European Communities hope to be a true common market and thus, in due ourse, a dominating economic force in Europe The chiefly French fear that the process will be interrupted by ambitions for the reunification of East and West Germany are not over-serious the frenzy of the past few weeks will soon abate, to be replaced by mutual recognition that reunification is at best a distant prospect Why should two of Europe's three-and-a-third German-speaking countries (counting Switzerland ungenerously as a third) consider they have no choice but to turn the clock back almost half a century, especially when their boundaries have changed considerably since 1939 and when there are much more interesting avenues for them to explore?

The interest of Europe is its diversity So much can be told from comparing a journey from Stockholm to Naples with one from, say, Omaha (Nebraska) to Austin (Texas), roughly the same distance It is remarkable that the countries of Eastern Europe have kept their own distinctive character throughout the past 40 years Now there will be even more diversity to conjure with The danger is that its interest will be complicated by ethnic or, more accurately, linguistic tensions Many of the new near-democracies are artificial states, glued together at Versailles and Yalta, after the First and Second World Wars The temptation now will be to unravel these ancient packages, reuniting patches on the map of Europe as if solving a jigsaw puzzle, sometimes even carrying out gigantic programmes of 'repatriation'

These temptations are natural, but should be suppressed by those in whom they arise In the present heady atmosphere, people may forget that the Second World War began with hankerings of this kind What Europe most needs now is a moratorium on external boundary changes Internal changes are a different matter, if people thrown together in some past jigsaw game so dislike each other, fission should be allowed Nobody would wish the present state of Belgium on, say, Czechoslovakia, but there must be better ways of letting people sense that they are in charge of their own affairs That is why German reunification would be a bad precedent

The better bet for everybody is that mobility, allowed for and even encouraged by the Helsinki agreements of 1979, should have a chance to make all European states more prosperous A precondition would be that the members of the European Communities should be at least as open to other European states as they are to each other That may be easier now that Europe's superpower hankerings have been attenuated with the cold war whose fighting kept them alive Gorbachev's common European home might then be a collection of smaller communities, a kind of Switzerland writ large Maybe that is what he is driving at even in the Soviet Union □

Uranium bites dust

The British government seems bent on letting past investments in nuclear power be wasted

THE British seem to have a flair for indecision from which even the present decision-prone government is not immune The failure to decide what should happen to the goods and people delivered to South-East England by the Channel Tunnel a few years from now would be a joke were it not likely to become a reality Now, a modest programme of nuclear construction has been abandoned after a decade's costly effort by engineers, bureaucrats and lawyers, but for reasons not strictly concerned with the safety of nuclear power or with long-term economics It is as if the British government shares with its predecessors a liking for the sensation of sand running through its fingers

Ten years ago, the government came to office with a plan for building nuclear reactors to the Westinghouse pressurized-water design at the rate of roughly one a year Construction of the first generating station (with two reactors) began two years ago at Sizewell in Suffolk, on the North Sea coast The project has been enormously delayed by the decision that a public planning inquiry should be a 'generic' inquiry, dealing with general matters as well as the suitability of the site The hope was to save time later in the construction programme But the second public inquiry, in respect of a site at Hinckley Point on the Somerset coast (which closed last week) has been almost as long and painstaking Indeed, the inquiry outlasted the nuclear programme itself, which was formally put on ice last month

The explanation is simple, but not straightforward The British nuclear programme has been a casualty of the government's determination to sell the electricity industry to private investors The first stages of this huge exercise will begin next year, with the privatization of the electricity distribution companies The sale of the generating plants, which will follow in 1991, has always seemed more complicated Originally, it was planned that there should be two generating companies (one large and one small called National Power and Powergen respectively) to simulate competition Now there is to be a third, whose plant will consist of all the nuclear stations operating or being built It may just be on the point of going out of business when the greenhouse effect prompts another British nuclear programme

The origins of this development are not obscure, but concern the high costs of operating a series of unsuccessful and uneconomic reactors called AGRs (for "Advanced Gas Cooled") as well as the estimated costs of decommissioning a previous generation of reactors National Power, the larger of the generating companies which was to have had responsibility for nuclear generation, may now kick itself for have lobbied so successfully to shield its future shareholders from hardship by frightening the government with worst-case costs

The effects of the decision are nevertheless curious The new nuclear company will be cast in the mould of the Atomic Energy Authority created in the 1950s as the spear-carrier of the new nuclear industry Over 40 years, the authority has consumed a substantial fraction of Britain's engineering skill, together with substantial amounts of money It remains a technically excellent organization, but without a nuclear programme, it might as well be renamed (its Harwell laboratory has become an excellent engineering and materials laboratory) or even be wound up when the fast reactor programme in Scotland comes to an end Future British governments may find it simpler, on future occasions, just to dig holes in the ground and fill them in again □

Generating physicists

A British minister hopes that compulsory physics will make more physicists, but he could be wrong

STUNG by the example of the Japanese, all industrialized states are these days worrying about the sufficiency of the supply of technical people, scientists and engineers in particular Generally speaking, there are too few of them Generally speaking, the poorer industrialized economies are the most deprived There is no accident in that science education costs time and money, at least in comparison with the language and literature of the region (unless, ironically, the language is Japanese) Even so, it is curious that one of the British government's least celebrated innovations of the past few years is the introduction of a national curriculum for primary and secondary schools, partly with the objective of increasing the supply of scientists and engineers How will it work out?

To judge from what Mr Alan Howarth, a minister at the British Department of Education and Science, was saying the other day, not much has changed Speaking to the Institute of Physics, Howarth said last month that the national curriculum, by introducing students to physics at an early age, must eventually increase the supply But the truth could easily be quite different Past experience in British schools with the old curriculum, allowing for specialization at too early an age, shows that there is nothing like a poor teacher to drive young people into other pursuits Howarth was promising more teachers the other day, but will they be good teachers? And if not, may it not be the worse for science education that young people should be forced to sit through classes that will convince them that they should opt for the arts and humanities?

If Howarth really had the supply of technical people at heart, he would settle instead for a compulsory curriculum that did hardly more than persuade young people that these technical fields are interesting and important, letting them learn to be professionals when they are ready for the task □

Back to the drawing board for Yucca Mountain repository

- DoE admits research was inadequate
- Government to sue Nevada for right to dump?

Boston

PLANS by the US Department of Energy DoE) to build the nation's first and only high-level nuclear waste repository were et back to square one last week when a op-ranking DoE official unexpectedly acknowledged that the department lacks confidence in its research on the facility and will completely revise the project The announcement effectively scraps the $500-million-worth of research on the epository site, at Yucca Mountain in Nevada, that the DoE has conducted over he past two years And the sudden change of heart throws the future of the high-level waste dump into uncertainty, a position that is exacerbated by an imminent legal showdown between the federal government and the state of Nevada

Disclosing the overhaul of the programme at a nuclear industry convention n San Francisco, Deputy DoE Secretary W Henson Moore said that even with 'optimistic assumptions" the new changes will cause a delay of at least seven years in the project As outlined by Moore, the department's revised timetable means that the repository will not open until the year 2010 at the earliest — 12 years beyond the 1998 deadline imposed originally by Congress when it commissioned the high-level waste project in 1982

Further clouding the facility's fate is the fact that the congressional instruction to the DoE is not to build the repository, but merely to assess the suitability of the proposed site, which lies deep in the volcanic rock of Yucca Mountain, 100 miles northwest of Las Vegas, Nevada The new schedule pushes even this approval process beyond the year 2000, and if Yucca Mountain were then deemed unsuitable, the search for a suitable repository site would have to start anew

The DoE's research on the site until now has been roundly criticized by the Nuclear Regulatory Commission and other agencies, as well as by some of the DoE's own scientists Some observers have praised the DoE for its candour in repudiating its previous work The DoE has now promised that future research on the facility will be subjected to review by the National Academy of Sciences, by the state of Nevada and by industry

But news of the programme's setback has been greeted with dismay in the nuclear industry The cooling ponds which between them hold hundreds of thousands of spent fuel rods from the country's 110 nuclear power plants are filling rapidly, many are nearing capacity, and some plants have already been forced to build new temporary waste facilities to allow operations to continue

US electricity utilities have already raised some $3,000 million from ratepayers for the construction of a waste repository More than one sixth of this money has already been spent on the now-abandoned research The DoE, meanwhile, is bound by contracts to begin accepting waste from the nation's electric utilities in 1998, and the utilities, having fulfilled their side of the bargain, balk at the idea of spending more of their money to build temporary storage facilities The DoE is expected to ask Congress for permission to build an interim storage facility in addition to the Nevada site

The state of California has already passed a law prohibiting construction of any new nuclear power plants until the issue of nuclear-waste disposal has been settled Some industry representatives have already begun to step in to this tangle of policy the Electric Power Research Institute, for example, a research group representing the nation's electric utilities, is said to have asked for a role in overseeing the work on the repository

Most observers believe that even the DoE's revised timetable is extremely optimistic Complicating matters further is the resounding rejection of the site by the state of Nevada In two bills passed last spring, state legislators exercised what they believe is their right to veto the Yucca Mountain site But Moore said the Department of Justice will sue the state of Nevada to force it to accept the site

Nevada legislators, including Governor Bob Miller, say they welcome the legal challenge They have opposed the process unflaggingly ever since they were singled out as the only site under consideration by a surprise congressional move in 1987

Most recently, the state has denied the DoE a permit to dig an exploratory shaft at the Yucca Mountain site Robert Loux, Miller's nuclear-waste policy coordinator, says he believes there are at least three separate issues in the case that could ultimately go to the Supreme Court As Loux sees it, the matter hangs on a simple question of state's rights "Shouldn't a state", he asks, "have a fundamental right to preserve its economy and environment in the face of a noxious, unwanted federal project?"

Seth Shulman

HUMAN FRONTIER PROGRAMME

Switzerland knocking on the door

Tokyo

JAPAN's Human Frontiers Science Programme, which opened its European office n Strasbourg on 21 November (see *Nature* 342, 334, 1989), is already attracting the nterest of countries not among the present participants Switzerland has offered support to the tune of $150,000 per year, and Sweden and Australia are also keen to join the programme

Switzerland's possible membership was discussed at a meeting of the Human Frontiers board of trustees in Strasbourg the day before the office opened Although the Human Frontier programme is underwritten by the Japanese government, the board of trustees consists of representatives from the G-7 group of Western nations (Japan, United States, Canada, West Germany, Great Britain, France and Italy) and the European Community (see *Nature* 339, 573, 1989) When Strasbourg was chosen as the European home of the Frontier programme, France made a financial commitment to the effort, and Switzerland has offered to pay for Frontier fellowships and to provide some financial support for grants and workshops In return, the Swiss want a place on the council of scientists that sets research goals for the programme At present, each of the G-7 nations has two scientists on the council

Some of the seven, including Japan, were keen to accept Switzerland's proposal immediately, but representatives of other nations felt that rules for accepting new members should first be established But Toichi Sakata, director of the Frontier office of the Science and Technology Agency, is confident that Switzerland will gain membership after the next trustees' meeting in April Sweden and Australia have also recently made proposals for membership similar to Switzerland's, Sakata says

The meeting included "tough" negotations over the secretariat that will manage the programme in Strasbourg Several nations were "aggressive" in their desire to get secretariat positions, says Sakata But he takes this as a positive sign of interest As well as appointing Sir James Gowans of Great Britain as secretary general (see *Nature* 342, 463, 1989), the meeting also created permanent positions on the secretariat for France, West Germany and Japan Other nations will contribute experts as needed The board of trustees also approved nominees for the council of scientists (European Community members have yet to be nominated)

David Swinbanks

How the earth moved . . .

San Francisco

ALTHOUGH Santa Cruz was the city closest to the epicentre of California's Loma Prieta earthquake on 17 October, the damage was worse in west Oakland and parts of San Francisco, a consequence of the way that complex local geology transmits the earthquake's energy After travelling around the entire Bay Area to survey the degree of ground motion, two teams of researchers from the United States Geological Survey (USGS) in Golden, Colorado, have made a preliminary estimate of the magnitude of the Loma Prieta earthquake according to the Modified Mercalli intensity scale, a qualitative measure of ground shaking, rather than the familiar Richter scale, which measures the energy released at the epicentre

The Mercalli scale runs from I to XII, with magnitude I being imperceptible and magnitude XII corresponding to complete destruction A rating of VIII, which was assessed by the USGS researchers for Santa Cruz and its immediate vicinity, is characterized as the threshold of structural damage to buildings — wood-framed houses move on their foundations and unreinforced masonry walls tumble to the ground But the localities that suffered the greatest destruction, west Oakland (where the Cypress section of Interstate highway 800 collapsed) and the Marina and Market Street areas of San Francisco, were assigned a IX rating

Researchers suspect that thick deposits of alluvium near these heavily damaged areas amplified seismic waves Alluvial layers of unconsolidated sediments and mud ring the perimeter of San Francisco Bay up to 200 feet thick, responding like "a bowl of jelly", absorbing and amplifying the seismic waves passing through the rock beneath, according to USGS geophysicist Paul Thenhaus

As a result, he said, "it's not unusual to get higher ground motions at long distances from the epicentre in a large earthquake" Indeed, similar circumstances beset the 8 1 magnitude (Richter) earthquake on 19 September 1985 that devastated large parts of Mexico City Even though the earthquake's epicentre was 350 km away, the city suffered widespread damage because its central and eastern portions are largely on an old lakebed

The Mercalli rating does not provide a completely clear picture of the Loma Prieta event Single-storey buildings in Santa Cruz fared much worse than those in San Francisco and Oakland, although the latter were shaken harder The discrepancy results from differences in propagation between low- and high-frequency seismic waves, and from varying resonances of different kinds of building (see *Nature* **341**, 676, 1989) Also clouding the analysis was the liquefaction of sandy soils, particularly in the San Francisco Marina district, which led to serious damage even though the ground motion was relatively small in that area To corroborate their assessments, the USGS teams studied areas of similar damage that appeared to be uninfluenced by such ground effects

In addition to their direct observations, the researchers incorporated results from 1,313 questionnaires, distributed to posi masters and police and fire station around California and in parts of wester Nevada and southern Oregon, asking fc eye-witness accounts of the effects of th earthquake Not all the forms, whic include 63 questions with up to seve different answers each, have been re turned Carl Stover, head of the U Earthquakes Project for the USGS, doe not expect a final report, incorporatin data from research papers and othe sources, to be complete for two years

Robert Bude

. . . and the pollution didn't

San Francisco

WHEN the San Francisco Bay Bridge, a section of which collapsed during last month's earthquake, reopened on 17 November after its month-long closure, local air-quality officials at first reported that the shutdown, which forced many commuters to leave their cars at home and travel instead by ferries and trains, had led to a measurable fall in air pollution from automobile emissions

But now officials of the Bay Area Air Quality Management District (BAAQMD) admit they may have spoken too soon An array of complications, including weather and heavier-than-normal car traffic on other bridges, seems to have made doubtful the hoped-for 'case study' of what would happen if people did not use the Bay Bridge

Researchers are now saying that they have no scientific evidence for cleaner air during the bridge closure, a great disappointment to BAAQMD's board of directors, which had hoped to drive home to the public the benefits of staying off the roads

The San Francisco Bay Area, with some 5 5 million residents, is the fourth-largest US metropolitan area Before the earthquake, 243,000 vehicles crossed the San Francisco Bay Bridge daily, and the area's four other main bridges carried a total of 273,000 vehicles These cars, trucks and buses contributed half of the 500 tons of hydrocarbons released daily into the atmosphere, and 90 per cent of the 3,000 tons of carbon monoxide Of the two, hydrocarbons, which are precursors to the formation of ozone and thence of smog, are regarded by air-quality officials as the more serious pollutant

At first, BAAQMD officials simply removed the Bay Bridge vehicles from their calculations, and guessed there should have been a 6 7 per cent reduction in hydrocarbon and carbon monoxide levels while the bridge was closed But figures collected at four alternative bridges showed their traffic went up to 435,000 vehicles a day during the Bay Bridge closure, making up two-thirds o the difference Moreover, the extra traffi caused heavy congestion, and accordin to James Sandberg, section chief o meterology and data analysis for the air quality district, in slow-moving traffic th emission per car goes up

Added to this complication is the fac that ozone forms only when the weather i warm enough to provide the radian energy to drive the needed photochemica reactions And during hot weather a inversion layer of warm air sits over th surface, trapping and concentrating pollutants

In the moderate Bay Area climate ozone levels have never exceeded federa standards from mid-October until earl spring "It's just not our ozone season" said Milton Feldstein, BAAQMD's air pollution control officer

Even if all the cars in the area hac stayed off the roads, there probably woulc not have been a measurable change ir ozone levels

"I hate to say maybe we should have had the earthquake in September when i was nice and warm, because they'll lynch me", said Feldstein

The end result is that ozone level during the Bay Bridge closure were dowr slightly, but did not go beyond the bound of normal seasonal variations, making an useful scientific conclusion impossible But that does not mean the unique case study of the failed bridge is a total loss Researchers are now trying to determine more exactly the number of cars on the road in the month following the earthquake

Taking into account the slower speeds caused by increased congestion, they will then try to make a more accurate projection of emissions reductions and create a computer model to see if the decrease in emissions would have made a difference in ozone season Feldstein said that BAAQMD might then still obtain evidence to convince people of the virtue of staying off the road

Robert Buderl

INTELLECTUAL PROPERTY RIGHTS —

Copyright *vs* patents for software

Washington

Disagreements within the computer science community over the best way to protect software surfaced last week at a discussion meeting organized by the computer science and technology board of the National Academy of Sciences Software has traditionally been protected through copyright laws, but researchers are increasingly taking out patents on their programmes, and are divided over the issue of whether patent protection should be strengthened or weakened

Among the problems created by the recourse to patent law is the delay in processing applications at the US Patent and Trademark Office (PTO), and the ambiguity of some patents issued, which has on occasion erupted into expensive law suits The PTO is also causing irritation among academics and industrialists in the computer science community by issuing patents for software that many consider too unoriginal to merit protection Robert Spinrad of the Xerox Corporation complained that the confusion was having a "stultifying and dulling effect" on the industry Dan Brinklin, now president of Software Garden Inc , who was forced to sell his former company after a successful but expensive patent dispute, said that the software industry is "very scared" by the patent process

The debate centred upon what would best serve the public interest John Schoch of Asset Management Company, a venture capital group based in California, argued strongly that patent protection must be strengthened as this encourages innovation and therefore benefits the public But Anita Jones of the department of computer science of the University of Virginia argued that patent protection should be weakened because the public benefit lies chiefly in the unrestricted dissemination of information

There was also disagreement over the use of copyright to protect software Although some complain about the copyright system, it has the advantage of being enforceable worldwide through international copyright agreements

Howard Figueroa, vice-president of commercial and industry relations at IBM Corporation, was among those who spoke strongly in favour of the current system which relies heavily on the use of copyright His response to heated discussion between those who favour strengthening patent protection and those who would like to see it weakened was "if it ain't broke don't break it"

The 20–25 per cent annual growth in the computer software industry in the past 10 years proves that the current system is working, and the problems could easily be put right he argued

Christine McGourty

INTERNATIONAL PATENTS

Late award reveals problems

Tokyo

After waiting for three decades, the US electronics giant Texas Instruments (TI) has been awarded a Japanese patent for the technology that forms the basis of nearly all integrated circuits The patent is expected to bring in hundreds of millions of dollars in royalties and will provide a powerful bargaining tool for TI in renegotiations of cross-licensing agreements with Japan's electronics companies But although TI has hailed the agreement as a new sign of respect for intellectual property rights in Japan, the prolonged process of patent application only highlights the problems that foreign companies face in protecting their rights in Japan

The newly patented invention goes back to 1958, when Jack Kilby, a TI engineer, showed how to build transistors, capacitors and resistors together on a semiconducting substrate to make an integrated circuit A US patent was applied for in 1959 and awarded a few years later A Japanese patent application was filed on 6 February 1960 But the Japanese patent office objected to the broadness of the application, which was then split into several smaller claims

But still objections were raised and the proceedings delayed, and only on 27 November 1986 was the central part of the original patent application accepted and published by the patent office

Many of Japan's electronics companies immediately filed opposition proceedings but finally, on 30 October this year, the patent was granted

The Nihon Keizai Shimbun, a financial newspaper, reported the patent award two weeks ago and predicted that it could bring TI royalties of as much as ¥80,000 million ($550 million) a year

But most of Japan's semiconductor manufacturers already have cross-licensing agreements with TI, and they are expected to trade other technology rights, rather than pay royalties, when their agreements with TI come up for renewal in the next year or two

But smaller manufacturers, as well as newcomers to the semiconductor trade, which do not have leading-edge technology to barter with, are expected to have to pay out large amounts in royalties, according to analysts

Masahiro Miki, a spokesman for TI Japan, says the patent award shows the importance that Japan is now attaching to intellectual property rights And he points to TI's success in suing Japanese and Korean companies in 1987 for violations of the company's patent rights for dynamic random access memory (DRAM) technology as another good men But he refused to discuss why the Japanese patent office took more than 29 years to process the Kilby patent

Compared to US patents, Japanese patents tend to be much more narrowly defined, each covering minute aspects of an innovation

The Japanese patent office is flooded with about half a million patent applications a year, which take on average 5–7 years to process In the United States, by contrast, 200,000 applications come in every year, and most are dealt with in 18 months

According to Mitsuru Miyata, editor of the newsletter *Nikkei Biotechnology*, the Japanese patent system is designed not for the protection of intellectual property rights but rather for the import and use of foreign technology Japanese companies seldom fight each other over patent rights, he says instead, competitors go out of their way to file narrow patent applications that differ from each other in only some minor respect, allowing them to compete commercially without violating each other's patents

When a foreign company tries to protect a broad technological invention in Japan, it is forced to break down the patent into a series of narrow applications, each of which has to fight its way through the system The delays provide a crucial advantage for Japanese companies If TI had been awarded its patent 5 or 10 years ago, it would have been a far greater financial burden for Japan's electronics giants, because they then lacked the sophisticated technology then they use in cross-licensing agreements with the US company

This is not the first time the Kilby patent has been at the centre of confrontation between the United States and Japan over technology In the 1960s, the Ministry of International Trade and Industry (MITI) rejected initial efforts by TI to set up operations in Japan, according to David Lammers of the Tokyo office of the Electronic Engineering Times But the US company suggested that any Japanese integrated circuit incorporating the Kilby patent would be barred entry to the US market and so MITI backed down, Lammers says

Although TI says the award of its patent is a sign of change for the better in Japan, the irony is that under present Japanese law the patent would never have been granted Under current rules, a patent application expires 20 years after the application is filed or 15 years after publication, whichever comes first, says Yasunori Ohtsuka, a patent lawyer in Tokyo But the TI application in 1960 was submitted just two months before the current law came into effect, and under the old law, which still applies to the US company's case, there is no time limit

David Swinbanks

SOUTH AFRICAN RESEARCH

Science budget falling behind

Cape Town

RESEARCH prospects in South Africa are looking bleak Although next year's budget has yet to receive formal approval, the Council for Scientific and Industrial Research (CSIR) is expecting an increase of at most 4 per cent With inflation running at 15 per cent, and research costs hit further by the weak rand, significant cutbacks are inevitable Even so, science and education seem to be relatively well-treated by the de Klerk government, which is making a concerted effort to curb state spending, a 15 per cent cut in the defence budget, for example, has been suggested

Worst affected has been the CSIR's Foundation for Research Development (FRD), whose responsibility its head, Rhein Arndt, describes as "manpower development in science and technology"

This includes the funding of university research and the provision of student grants Last year, the CSIR's national laboratories were taken from FRD and given to another arm of CSIR, Research, Development and Implementation (RDI) (see *Nature* **332**, 197, 1988) The aim was to move towards 'near-market' research, and the RDI has been successful in supporting research with contracts from government departments and the private sector Last year, 38 8 per cent of the CSIR's income was derived from outside contracts, and this is expected to rise to 41 5 per cent this year In compensation for this move, the FRD expected to get more of the CSIR's overall budget as the RDI became more self-financing But this has not happened this year, FRD was allocated the same proportion of total government support as last, and no change is expected in the coming year The net effect has therefore been a shift of money from basic to applied research

Although the CSIR's grant is negotiated from the Treasury by the Ministry of Trade, Industry and Tourism, the RDI and the FRD budgets are considered to be separate entities, and are dictated by the government The cabinet is currently considering a request by the FRD to be moved to the national education budget, which is in the hands of Minister Gerrit Viljoen He is more enthusiastic about basic research, and also seems to have the ear of President F W de Klerk

The FRD also runs the country's four national research facilities the South African Astronomical Observatory, the Radio Astronomy Observatory, the Magnetic Observatory and the National Accelerator Centre (NAC) Last year, NAC alone cost CSIR R30 million ($12 million), 34 per cent of the CSIR budget, and many of the country's scientists feel that NAC is an under-used and unaffordable luxury

Last month, FRD initiated an independent review, by scientists from outside South Africa of the quality of work being carried out at NAC, its impact on the development of technical expertise in South Africa, and NAC's place in the country's science system Arndt says that the future of NAC is "something that the science community will have to take a hard decision on"

At the root of all these problems is the small proportion of gross domestic product (GDP) that South Africa spends on research and development In 1987, research and development spending from all sources amounted to 1 per cent of GDP (R1,700 million, or $700 million), with roughly equal amounts coming from government and the private sector This is a much smaller proportion than is spent by Britain or France (2 3 per cent of GDP in 1987), and is less even than India (1 1 per cent) **Michael Cherry**

SPACE AGENCY

Arianespace forced to twiddle thumbs

Paris

TECHNICAL problems, small print and the San Francisco earthquake have left Arianespace, Europe's commercial satellite launch consortium, with nothing to launch this month, despite a full order book and a tight schedule

Originally, the French SPOT 2 commercial Earth observation satellite — the overdue replacement for the successful but ageing SPOT 1 — was scheduled for launch last month But 'technical problems' with the Ariane 40 rocket led Arianespace to delay the Flight 35 launch until December, pending further tests

However, the Superbird A satellite, built by Ford Aerospace for the Japanese, was also scheduled for a December launch and a postponement would have incurred penalties for Arianespace

So the consortium asked the French national space research centre (CNES), which owns SPOT, to let the Japanese satellite go up first

Because Spot 1 is still sending pictures, Spot 2 was rescheduled for launch on 10 January. In the meantime, Superbird A, which was undergoing final tests at Ford Aerospace in Palo Alto, was shaken by the San Francisco earthquake, and the manufacturers decided it would be unwise to send the satellite to the Kourou launch site without more tests As Spot 2 could not be taken out of wraps again at short notice, this has left Ariane-space with two launchers ready to go, but no payload

Peter Coles

SCIENCE EDUCATION

Technical studies to be compulsory

Sydney

AN ambitious reform of the education system in New South Wales will make the study of mathematics, science and technology compulsory for high school students in the province Under the present system, the only compulsory subject for final year students taking their Higher School Certificate is English, but by 1992, following the introduction of the government's white paper (policy document) on curriculum reform, students will also have to take at least one technical course

Until now teachers have been providing courses in technology and computing, of a mostly vocational nature, under a category known as Other Approved Studies (OAS) The government intends to reduce the OAS from 10,000 to 500 subjects, substituting new technology courses instead The white paper will also make it compulsory for 13–15 year-olds to study a language and a technology course In other changes to the curriculum, courses involving AIDS and drug education will be integrated into a new mandatory health and physical education programme

The government acknowledges that the major difficulty in the introduction of these reforms is a shortage of teachers of technology, science and mathematics A spokesperson for the Minister for Education said that the department would be negotiating with the NSW Teachers' Federation for a salary increase for staff in these fields But the teachers are unlikely to go along with such changes Sue Simpson, spokesperson for the NSW Teachers' Federation, said she found the suggestion of differential rates of pay surprising, and argued instead for "an overall increase in teachers' salaries to entice teachers back into the system"

Tania Ewing

ASTRONOMY FROM SPACE

Solar max falls at last

Washington

THE Solar Maximum Mission satellite (SMM), launched in 1980 to observe flares and other activity during the peak of the last solar cycle, almost survived until the peak of the present solar cycle, expected in about four months But last Sunday morning, 3 December, it re-entered the Earth's atmosphere and burned up over the Indian Ocean near Sri Lanka In 1984, SMM became the first satellite to be successfully retrieved, repaired and returned to orbit by the crew of a space shuttle mission SMM's swansong was its observation of gamma-rays from Supernova 1987A, which provided the first observational confirmation that supernovae remnants are powered for the first year or so by the radioactive decay of ^{56}Ni synthesized in the initial explosion (see *Nature* 331, 416, 1989) David Lindley

EAST GERMAN GREENS

Grappling with dirty past

Munich

THE East German environmental movement took its first shaky steps toward political responsibility last week with the formation of the 'Green Party of the German Democratic Republic' In its first statement, the party criticized materialism and advocated reducing environmental pollution

But the party founded over the objections of other ecologically minded people in East Germany, will have to develop a more solid programme in the next few months if it is to achieve even a fraction of its goal of ecological reform in a socialist framework Nevertheless, the founding of the party was considered significant enough to be reported widely in the East German media and to attract support from the West German Green Party

Co-founder Gerhard Bacher admits that winning support will be difficult in a country where everyone pays lip service to ecology Even members of the ruling Communist Party have called for an "ecological reconstruction" of the country Bacher says that the Greens have received anonymous phone calls from Communist Party members insinuating that they have shown right-wing tendencies

A bigger threat is the fragmentation of green thought between the new party and other left-wing groups such as New Forum Bacher claims that the difficulties have been dealt with, but a West German Green who visited last week said that many disagreements remain Members of the opposition movement New Forum also fear that they could be split by difficult choices between preserving the environment in East Germany or opting for profitable but polluting activities that bring in hard currency The environmental side had been gaining ground in East Berlin earlier this year, but the collapse of the government and the need to earn Western money may turn the tide

If it can arrive at a common platform, the Green Party will have a lot to do in East Germany, which has always relied for energy on soft bituminous coal Huge strip-mining machines have churned up the countryside, and when the coal is burned, sulphur compounds are released directly into the atmosphere Smog is a permanent problem in all East German cities, made worse by the black, foul-smelling exhaust from the two-stroke engines of Trabants, the least expensive East German cars

The East German Greens are probably the only Green Party in the world that favours nuclear energy, but they support it only for want of alternatives But their support does not extend beyond completing the nuclear power plant at Stendahl that is under construction They are against new plants, but can suggest no likely alternatives that East Germany can afford

Although East Germany has never had a significant nuclear accident, the uranium mines in the south of the country have been a continual health threat for East Germans who live nearby The East German government has begun to publish radiation and air pollution figures for the first time in its history

The East German Greens will be preoccupied with such basic issues for a long time before they need to consider genetic engineering and other technologies that exercise the West German Greens

What may be the biggest challenge fo the Greens in East Germany has little t do with ecology Bacher warned agains a "disturbing" tendency to favour reunification with West Germany as a way t help East Germany out of economi decay, saying that the West German styl of economic success has its consequences not least for the environment "People' eyes popped out" on their trips to th West during the first weeks after th opening of the wall, said Bacher, but h and his party hope to convince them tha they should consider the price befor buying the goods

Steven Dickma

IN VITRO FERTILISATION

Reformation of advisory board urged

Washington

THE US Congress can now be added to the list of agencies trying to prod the US federal government into reconstituting the Ethics Advisory Board (EAB), the committee with responsibility for overseeing research on *in vitro* fertilization (IVF) In a report issued this week, the House of Representatives committee on government operations urges the government to abide by the regulations of the Department of Health and Human services which require it to set up the board It is an "embarrassment" to the department and to the Public Health Service that the last five secretaries for health have ignored these regulations, says the committee

It also urges the present Secretary for Health, Louis Sullivan, to implement the board's recommendation, made in 1979 before its charter was allowed to expire, to exempt research on embryos less than 14 days old from the need to be reviewed by the EAB Other restrictions would be adequate, such as requiring the informed consent of the couple from whom the embryo was generated or restricting the number of eggs that can be fertilized

Reinforcing the comments made by the Institute of Medicine in a report issued in November (see *Nature* 342, 218, 1989), the committee complains of the inadequacy of current IVF research and the poor infertility services available

In line with the controversy surrounding this issue, five of the 15 Republican members of the committee signed a dissenting statement which says that there is no evidence that significant increases in federal funding for this research will improve its quality It also says that there are fears that an increase in funds for infertility research could strip funds from AIDS research, and that, because the private sector is involved in this research, this is "not the best use of scarce tax dollars"

Christine McGourty

COLD FUSION

An old-fashioned love-song

Tokyo

Cold fusion reared its head again las week in Japan with two independen research groups claiming to have detecte strong neutron bursts from electrochemical experiments The news was splashe across the front pages of newspapers reported on national television an picked up by the US *Wall Street Journal* But Japanese experts on neutron monitoring are sceptical

Kunihide Nishizawa and Nobuhik Wada of Nagoya University say the detected neutron emissions 20,000 time background levels from palladium electrodes that had been soaked in deuterium gas then subjected to a high voltage Clos on the heels of this announcement, a grou at Osaka University, headed by Yoshiak Arata, claimed to have detected neutro emissions 25,000 to 2 5 million time background levels when a voltage wa applied to thick palladium rods immerse in heavy water

But, according to one Japanese expert the detector used by both groups, called a BF3 counter, is intrinsically very sensitive to vibration, and sometimes shows pulse like signals unrelated to neutron emission Wada and Nishizawa should presen pulse-height data before they clain neutron detection, he says

The Osaka University results are more highly regarded, because multiple detectors were used and pulse-height data were presented But neither group has examined the energy spectra of the neutrons and thus cannot claim that fusion is the cause, experts say As one researcher from Japan's new National Institute for Fusion Science put it "we want evidence that the signals arise from neutrons due to nuclear fusion processes" but "some Japanese scientists still sing an old-fashioned love song composed by Pons and Fleischmann" **David Swinbanks**

SPACE EXPLORATION

NASA outlines path to Mars

Washington

PRESIDENT George Bush's vision of lunar and martian exploration, made public on the twentieth anniversary of Apollo 11's Moon landing (see *Nature* **340**, 249, 1989), is so far no more than a vision Trying to inject some reality into these grand schemes, the National Aeronautics and Space Administration (NASA) last month released a report that offers five exploration strategies

But the report, the result of a three-month collaboration by all of NASA's divisions, confines itself to making suggestions, which come without price tags, that the president's National Space Council might wish to adopt with a view to working them up into detailed plans

In the first strategy, the astronauts return to the Moon in 2001 and occupy a lunar base permanently in the following year, the first mission to Mars is in 2015 But this tight schedule depends on accelerating the development of the space station so that its assembly is complete by 1997, two years earlier than planned

Financial problems have already forced NASA to plan a new 'rephased' space station programme which stretches out several parts of the programme by six months The Shuttle-C, a new cargo-carrying launch vehicle needed to ferry space station components from Earth, is the only new vehicle that could be ready in time to meet this schedule

In the second strategy, the first lunar mission is also planned for 2001, but the first human Mars landing is brought forward to 2011, delaying scientific research on the Moon but accelerating it on Mars This would require the concentration of funds in the first decade of the next century so that hardware for both the lunar and the martian outposts could be developed in parallel

NASA also outlines a third possible plan which is similar to this one, and a fourth which delays the major milestones by two to three years

In the final strategy, all the major steps in the programme are delayed the return to the Moon is in 2004, the first landing on Mars is in 2016 and a permanent Mars outpost would not be ready until 2027 Research on the Moon would begin around 2007 with Earth-controlled geological and geophysical exploration, establishment of the astronomical telescope arrays and human biomedical research in the lunar laboratory In 2022, there would be a piloted flight to the far side of the Moon for geological exploration and to set up a radioastronomy and geophysical observatory

To carry out this programme, NASA says it will need a substantial increase in staff numbers, from the 24,000 permanent staff it has at present But it complains in the report about the "antiquated" federal employment structure which keeps salaries and benefits low, making it difficult to recruit high-quality scientific and technical personnel in the increasingly competitive marketplace

NASA also wants to change the rigid budget process which allocates funds on a two-year basis, resulting in short-term planning and instability When NASA was established it was granted "no year" funds which it did not have to spend within an established time period, and it had greater flexibility to alter programmes, to accept gifts, to buy property and to enter into contract on any terms and conditions it deemed necessary With new legislation and regulations, these powers have been gradually eroded, but NASA says that the complexity of a 30-year lunar and Mars exploration programme necessitates change NASA has not yet attempted a programme of this size, requiring such long-term development, and unless existing legal regulatory structures are changed, there will be "a severe penalty in schedules, resources and efficiencies" it says

Christine McGourty

MOLECULAR BIOLOGY

Belgium joins EMBL

Heidelberg

BELGIUM has become the fifteenth member of the European Molecular Biology Laboratory (EMBL), director Lennart Philipson announced last week The additional support of roughly DM1 5 million ($840,000) a year, plus an entry fee, is a modest addition to EMBL's budget, but the new funds, says Philipson, will allow EMBL to increase the number of fellowships it awards The exact use of the money must be determined by the EMBL council Like all member states, Belgium will contribute to EMBL in proportion to its gross domestic product Its yearly payment will provide about 3 1 per cent of the DM49 million ($28 million) EMBL budget

Steven Dickman

CONSERVATION

Too many cooks preserve diversity

Washington

THE preservation of biological diversity in the United States and worldwide is a project with many supporters Paradoxically, that seems to be causing trouble Earlier this year, the National Science Foundation (NSF) argued that, because of its long-standing support of ecological research, it should be given a role in national efforts to document and preserve plant and animal species (see *Nature* 340, 585, 1989) Meanwhile, plans have been stirring in Congress to set up a National Center for Biological Diversity with the Smithsonian Institution at its helm, but at a congressional hearing last month Robert Jenkins, vice-president for science programmes at the Nature Conservancy argued that his organization ought to play the lead role because of its past and continuing efforts in species preservation

The purpose of the hearing, before a subcommittee of the House of Representatives committee on Merchant Marine and Fisheries, was to discuss two principal questions embodied in proposed legislation the establishment of a national centre to coordinate data collection and research concerning biodiversity, and to incorporate into the charter of various federal agencies language to make species preservation a particular concern At present, only the National Forest Service (NFS) has such language in its charter David Wilcove, an ecologist with the Wilderness Society, argued that the NFS had not traditionally put conservation issues high on its list of priorities, and cited the case of the northern spotted owl, which inhabits forests of the Pacific northwest NFS forest management, Wilcove claimed, had given over such quantities of the owl's habitat to logging that the Fish and Wildlife Service, another federal agency, was now arguing for the owl to be listed as an endangered species

It was agreed by all that the Endangered Species Act was ineffectual in preserving general biodiversity, and that some mechanism was needed to enforce conservation regulations before species were threatened to the point of extinction But while there was general satisfaction at the hearing with the idea of a national centre run by the Smithsonian, Jenkins protested that the Nature Conservancy, a private non-profit organization, had been running such a programme on a small scale for many years

Its Heritage Program, he said, was ready to receive federal support that would expand it into the National Center for Biological Diversity of proposed legislation, and suggested an amendment of the law that would give the Nature Conservancy the appropriate leading role But Jenkins seemed to be in a minority of one George Davis of the Academy of Natural Sciences of Philadelphia said there was "plenty the Nature Conservancy is not doing" and that only a suitable federal body would have the authority to enforce interagency collaboration

Fair shares for Japanese

SIR—Japan's government institutions are now advertising their scheme for hundreds of foreign postdoctoral fellows (see S S Siddiqui, *Nature* **340**, 337, 1989 and recent advertisements in *Nature* Classified) It is good to know that our research institutions, as well as universities, have finally decided to open their doors to researchers from outside Japan I welcome our government's decision to make its laboratories international, its efforts (including high payment) will be appreciated by foreign researchers and probably by politicians, in spite of the difficulties experienced by foreigners living in Japan

At the same time, however, it is regrettable that non-tenure-track Japanese researchers cannot similarly join laboratories as fellows The time is now ripe for our laboratories and universities (both now training too few post-PhD fellows) to show Japanese PhDs how they can carry out postdoctoral research in their own country If it does not do so, Japan will miss an opportunity to keep promising young scientists wanting experience in laboratories in different fields

YASUSHI SAOTOME

Yokohama 222,
Japan

SIR—I read with interest the article by S Berliner III (*Nature* **341**, 379, 1989) pointing out the difficulties of using the 2,000 characters of the Japanese language As he recommended, the Japanese should, as a short-term measure, use bilingual signs in Japanese and English in public places, and should transcribe Japanese characters into roman letters for foreigners As a long-term solution, however, do we really have to reform our language, which has the merits of both ideograms and phonetic signs? During my five years in New York, I found that English-speaking people overlook the fact that the language–brain interface is more important than the language–machine interface

If a sentence written with simple characters like the alphabet is easy to understand, why is machine language composed of only 0 and 1 so difficult for humans? The brain is well suited to recognizing patterns such as faces (*Brain Res* **342**, 91, 1985) and ideograms, and a concept is easily associated with the corresponding ideograms even in a patient with aphasia (*Cortex* **8**, 265, 1972) Japanese sentences are easy to read because they are composed of lexical portions, written with *katakanas* (phonetic signs to express foreign words) and 1,945 basic Chinese characters, and grammatical formatives with *hiraganas* (the other phonetic signs)

In fact, the circulation of newspapers in Japan is the highest (58 per cent) in the world (20 per cent in the United States), and many attempts to persuade Japanese to read newspapers and textbooks written in English or roman-lettered Japanese have failed The percentage of total time spent on language during elementary school is only 25 per cent in Japan but over 40 per cent in the United States, and there is almost no illiteracy in Japan This easy Japanese education has resulted in a flourishing society

The disadvantage of Japanese in writing has now been overcome by the widespread use of Japanese word processors and facsimile machines Memorizing ideograms is easy for children, but not for adults Thus, millions of biological species and chemical compounds must be written in *katakana* instead of 80,000 complicated Chinese characters (*Biochem Educ* **16**, 37, 1988)

People should choose a language suitable for both their brain and their culture, not for the typewriter

Don't blame us

SIR—Your leading article "Research by numbers" (*Nature* 341, 674, 1989) quotes from a document setting out new resource management arrangements agreed last April between the Department of Education and Science (DES), the Treasury and the research councils, and wrongly suggests that these arrangements provided the basis for the government's decision not to finance the proposed national survey of sexual attitudes and behaviour

Your readers will want to know that under these arrangements it is for the research councils to decide whether to refer matters to the DES The initiative in seeking ministerial guidance is placed with the research councils, not with ministers

In the case of this survey, the government decided it would not be appropriate to provide financial support from the Department of Health's research programme or, more generally, to sponsor the survey The Economic and Social Research Council (ESRC) decided not to proceed on this basis Contrary to your account, the ESRC was not required to refer the matter to the DES nor did it do so

The resource management agreement was concluded after extensive discussion between the department and all the research councils It is designed to give greater freedom to councils in exchange for departmental scrutiny of councils' management systems It is not the purpose of the new arrangements to limit councils' freedom nor to intervene directly in their scientific judgements Any such agreement would have been unacceptable to the councils which continue to operate under the well established 'arms-length' relationship with the government, embodied in the 1965 act establishing the research councils

Creative force?

SIR—If A Travis (*Nature* **341**, 10, 1989) is personally having "flirtations with the untestable" and holds the belief that there is a "creative force manifesting itself in the observable universe", how does telling us this assist in furthering our understanding of nature? Surely you have received correspondence from others on more important and specific topics that better deserve column space?

The essential difference between religious beliefs such as Travis's and the "organized common sense" of science is that religion demands explanations, while science is, or should be, prepared to answer Nobody knows", and continue with its investigations

Formulating unanswerable questions and then demanding answers to them is a waste of time Formulating a theory to explain a feature of nature and then finding ways to test the theory is not If a way is not found to test the theory, then it must be shelved until one is A theory that life evolved here on Earth out of molecular interactions is in principle testable for example, we can perform individual steps in the process experimentally, we can simulate it in our computers and we may one day be able actually to do the whole thing ourselves The theory may be proved wrong, so therefore it is testable No one has come up with a testable alternative yet, so if this one is proved wrong, we must return to "Nobody knows"

Travis looks for and finds some "unknown creative force" in this theory That can only stem from his own religious desires for there to be one, for there is no mention of one in any of the statements of the theory that I have read

To me, the conclusion "Nobody knows" is far more awe-inspiring and stimulating than "we can't explain this, so therefore there is a mysterious creative force in the universe", which in my opinion simply shows a lack of imagination

Q: Why do we have radioactive waste anyway?

A: *All industries produce waste The nuclear industry is no different If we want the benefits of nuclear electricity and nuclear medicine we have to accept the waste But even if we could stop using nuclear technology, waste that already exists would still have to be safely disposed of*

Q What sort of waste is UK Nirex Ltd responsible for?

A *Only low and medium level radioactive waste Low level waste has been routinely disposed of for 30 years and medium level waste has been stored*

Tough questions. Honest answers.

Q: Why isn't radioactive waste stored in the place it's produced?

A: *Many reasons In particular it will be less safe in the long term to have stores dotted around the country close to man and the environment than to have one high quality disposal site protected by hundreds of feet of rock*

Q· What is the likelihood of radiation escaping and harming people?

A: *The chances of anyone being harmed are less than one in a million, which is about the same as the risk involved in smoking just one cigarette in a year Nothing can "leak" in the normal sense, as all the waste in a disposal centre will be set in concrete*

Q· What's to stop radioactivity leaking into the environment?

A *Multiple barriers are placed between the waste and the environment These include steel drums, layers of concrete and the carefully chosen surrounding rocks, which will contain the waste for many thousands of years*

Q: How will wildlife and plants be affected near the site?

A *Nirex will take great care to make sure that the environment is safe and the site will be carefully surveyed to protect any rare or unusual species*

Q Who is responsible for making sure the highest safety standards are upheld?

A· *Ultimate responsibility lies with the Secretary of State for the Environment along with the Secretaries of State for Scotland and Wales UK Nirex is also monitored by the Department of the Environment, the Ministry of Agriculture Fisheries and Food and the Nuclear Installations Inspectorate, as well as receiving advice on procedures from the National Radiological Protection Board*

UK Nirex Ltd , a company owned by the Central Electricity Generating Board, British Nuclear Fuels plc, the UK Atomic Energy Authority and the South of Scotland Electricity Board, is to develop and build a deep underground disposal centre for radioactive waste

If you'd like more answers on radioactive waste disposal just phone our Information Line on 0235 833009

The great gene shears story

John Maddox

Nature has been in hot water in Australia for supposedly misreporting the prospects for a new technique of genetic manipulation. The truth is more interesting and complicated than *Nature* (and many Australians) know.

Sydney

For the past month, *Nature* has been heartily reviled by many in Australia for the publication, on 12 October (**341,** 473; 1989), of a news report that an Australian patent application of which much was (and is still) expected had been anticipated by a patent application lodged earlier in the United States. The report has been especially hurtful to the Commonwealth Scientific and Industrial Research Organisation (CSIRO), which for the past decade, but especially in the past two years, has been under intense pressure from the federal government of Australia to win a greater commercial benefit from its substantial annual budget, but other officials of the federal government, ministers included, have also waxed indignant.

Further investigation, on a visit to Australia for other purposes, softens the assertion, in the report of 12 October, that an invention of which CSIRO, even Australia as a whole, is rightly proud has been fully anticipated by developments in the United States. To the extent that the report suggested that the Australian patent application is unambiguously pre-empted by the US patent claims, it is oversimple. But the relative status of the US and Australian claims is, to say the least, complicated and unclear. If the report had merely said (which it did) that the Australian claims will be fiercely disputed, it would have been correct.

Even so, *Nature* owes an explanation (unsolicited, as it happens) to those directly concerned — to CSIRO, to Dr Jim Peacock of the Plant Industry division of CSIRO, to Drs Wayne Gerlach and Jim Haseloff and to Mr Stephen Castle, a patent examiner at the Australian Patent Office (who was a casualty of the process of gathering the information on which the 12 October news report was based).

What follows is a circumstantial account of the origins of the disputed patents and of *Nature*'s two news reports on the subject (both that of 12 October and, earlier, on 3 August, **340,** 332; 1989). It is hoped that this account will be instructive (as well as interesting) for readers concerned about several features of the interaction between the scientific enterprise and the increasingly commercial environment in which it must make its way: the effects of commercialization on the open discussion of research; the extent to which publication policies are now affected by the consideration that patent rights should not be compromised; and the intricacies of patent law, with which researchers in many fields will have to become familiar.

The relationship between research and the news media is another of the issues that arises. In some ways, *Nature's* report lacked balance. But too little help was given by some of the respondents to its enquiries (although that is hotly denied).

Ribozymes

It is a shame that the research concerned, from which both the US and Australian patent applications stem, should be one of the neatest and potentially most important applications of genetic manipulation yet. Its origins are the recognition, within this decade, that intervening sequences ("introns") may in real life ("*in vivo*") be excised from freshly-transcribed RNA molecules to make functional molecules of messenger RNA (mRNA) without the intervention of extraneous enzymes — enzymes consisting of protein molecules, for example.

It was naturally a surprise, in the late 1970s, that it should have been discovered that genes of eukaryotic cells — stretches of double-stranded DNA helix — are not always connected pieces of helical DNA, and that functional pieces of DNA ("exons", where "ex-" stands for "expression") should be interrupted by apparently irrelevant stretches (called "intervening sequences", or IVSs).

Logic and cellular economy would argue that these irrelevancies should be irrelevant from the start, and thus never converted into RNA, but that is not what happens in real cells. Instead, the full length of a gene, introns as well as exons, is converted (transcribed) into a full-length molecule of RNA ("pre-mRNA") which is in turn converted into a molecule of mRNA somewhere in the nucleus. From the outset, this process (called splicing) has been a philosophical puzzle: for RNA transcripts to be accurately spliced, either the nucleus of a eukaryotic cell must contain a specification, distinct from the genetic DNA itself, of which stretches of RNA are to be excised, or the RNA transcripts themselves must contain a specification of how their intron sequences are to be removed.

In mammalian cells, many splicing processes turn on the recognition of splicing sites in RNA molecules by nuclear particles called small ribonuclear particles (RNPs). But it is now also plain that, for at least some introns, self-specified self-splicing is the rule. In other words, some introns embody both their own specification and the molecular mechanism by which they are excised. Dr Thomas Cech and his associates, of the University of Colorado at Boulder, have contributed substantially to this discovery in a series of articles in the international literature beginning in 1982. They have worked out the details of a mechanism by which introns are excised from RNA transcripts by means of intramolecular reactions between the nucleotides of the introns and those of the adjoining exons.

Among other things, Cech showed that some RNA molecules, entirely innocent of protein from which all previously known enzymes are made, can function as enzymes. He coined the term "ribozyme" to describe such enzymes consisting solely of RNA. The interest and importance of the discovery was recognized by the Nobel committees this year, which have awarded Cech the chemistry prize. The award is widely applauded. One member of the Canberra group whose work has prompted the Australian patent application says "we were astonished" by Cech's first evidence that introns could be excised from RNA molecules without the intervention of protein enzymes. Cech's Nobel prize, the

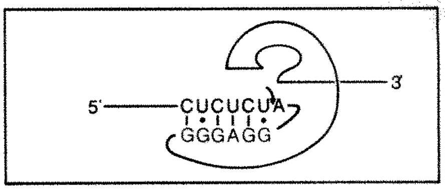

FIG. 1 Upstream splice recognition. The nucleotide sequence —CUCUCU is the end of the upstream exon, otherwise represented by the line labelled 5′. The nucleotide A is the first of the intron sequence, also represented as a line except for the six nucleotides —GGGAGG (reading from left to right), which are nucleotides 22 to 27 of the intron sequence in reverse order. Short vertical lines between pairs of nucleotides represent Watson–Crick (hydrogen) bonds between pairs of nucleotides. The directionality of polynucleotide molecules, whether RNA or DNA, is intrinsically determined by the way in which the linking phosphate groups can be attached either to the 5′ or to the 3′ position in the ribose (deoxyribose) ring of the sugar part of each nucleotide; because most, but not all, natural processes affecting polynucleotide molecules begin at the 5′ end, that is also called the upstream end or direction. From the Cech, Zaug and Been patent application.

patents examiners that their provisional judgements are mistaken.

The drift of the patent application rests squarely on the discovery, reported in January 1986, that the intron in the *Tetrahymena* pre-mRNA molecule can catalyse intermolecular reactions, and in particular carry out all the processes required for the removal of the intron, of which the most striking is the process by which an RNA molecule is cleaved at a predetermined sequence of nucleotides. The active ribozyme is the natural intron from whose 5′ end 19 nucleotides have been removed, and which is called L-19 IVS — L (for "linear"), "-19" (meaning "minus 19") and IVS (for "intervening sequence"). Figure 2 shows the functioning of this ribozyme in what may be its chief role as an RNA-restriction enzyme, or endonuclease.

The experimental conditions are important. Ions of Mg^{2+} are necessary, as is either guanosine (abbreviated G) or its phosphorylated derivative GTP. What then happens in self-excision is that, by a mechanism not understood, the RNA chain is broken after the recognition sequence of six nucleotides at the downstream end of the preceding exon.

Although the Cech, Zaug and Been patent application seeks protection for the enzyme functions of L-19 IVS other than its capacity to cleave RNA molecules — that of removing phosphate groups from the 3′ ends of RNA molecules, for example — they are less relevant to the Australian patent application and likely to be, in any case, less important. In the list of 73 claims in the Cech, Zaug and Been patent application, the second seeks protection for an "RNA enzyme" with "sequence-specific endonuclease" activity. Other more specific claims would protect the use of modified versions of the *Tetrahymena* ribozyme: the first two and the last of the 395 nucleotides may be eliminated from L-19 IVS without impairing its cleavage activity, while several examples are given of how the active (recognition) site of the enzyme can be modified so that it will cleave RNA molecules at places other than the join between a natural exon and an intron.

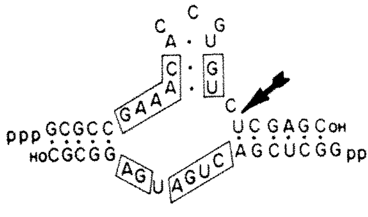

FIG. 4 Uhlenbeck's ribozyme. Two RNA strands synthesized by analogy with ASBV viroid sequences involved in a hammerhead self-cleaving region shown in the configuration in which they associate by means of Watson–Crick pairing. The lower strand is the 19-nucleotide ribozyme referred to in the text.

One question certain to arise in the months ahead is whether the claim for protection of endonuclease activity in the Cech, Zaug and Been application is so general that all further proposals for the use of ribozymes will be somehow subsidiary, at least in the United States (where Cech's prior publications are not, on the face if things, a bar to patent protection). The issue is not simply a matter of patent law and procedure; much will also depend on the commercial judgements of potential challengers of the relative costs of a challenge and a commercial compromise.

Further development

Apart from prompting a patent application, Cech's discoveries in the period 1982–86 seem powerfully to have stimulated other research groups already then concerned with the mechanism of self-splicing. One of these is the group of Robert H. Symons at the University of Adelaide, which has a long-standing interest in the mechanisms of splicing in RNA molecules, especially the RNA plant viruses and the RNA parasites of plants known as viroids and virusoids. Haseloff, one of the authors of the CSIRO patent application, was a member of this group as recently as 1982.

Symons and his associates appear to have succeeded in defining the necessary and sufficient structural requirements for self-cleavage in several of these plant RNA molecules. The results are neatly illustrated by the self-splicing of the virusoid of the lucerne transient streak virus (LTSV), which in its intact form consists of several virusoid particles, each a single-stranded RNA molecule 324 nucleotides long packaged, together with an RNA molecule ten times as long, into an icosahedral structure. The virusoids require the presence of the longer RNA molecule of the LTSV, and may themselves be formed as inactive rod-like particles of RNA in which the infective virusoid molecule is bound for most of its length to a Watson–Crick complementary "minus" strand. This rod like structure seems to be capable of splitting into two separate strands by self-cleavage (see Anthony C. Foster and R.H.Symons, *Cell* **49**, 211; 1987).

What Symons and his associates have shown is that both the plus and minus strands of the virusoid RNA (called vLTSV) are also capable of self-cleavage at specific places along their length, and that the sequence of nucleotides around that point will allow for a distinctive secondary structure of the RNA molecule, called graphically a "hammerhead" structure (see Fig. 3). Similar structures have been recognized in other plant virusoids, leading Symons and his colleagues to conclude that it is a structure prone to self-cleavage in which Mg^{2+} ions assist (but are not always necessary).

There is no suggestion that these hammerhead structures, recognized in RNA molecular parasites of plants, are involved in all RNA self-splicing; Cech's L-19 IVS is one exception; it is merely that the hammmerhead structure seems to be a sufficient condition for self-splicing in several natural RNA molecules. The work of Symons and his colleagues has been concerned exclusively with naturally occurring processes, and not with the design of molecules of RNA capable of acting independently as ribozymes in the strict sense.

Observations such as these show that a quite small stretch of RNA may be sufficient for self-cleavage, and it is natural that they should have helped to stimulate an attempt to define the minimum self-cleaving region. One important and relevant attempt in this direction is that of Ohlke C. Uhlenbeck from the University of Colorado at Boulder, a colleague of Cech's but not a member of his research group (see *Nature* **328**, 596; 13 August 1987).

Noting the demonstration by Symons and his colleagues of the effectiveness of hammerhead structures in the cleavage of plant parasite RNA, Uhlenbeck synthesized two RNA molecules with nucleotide sequences corresponding to those constituting the hammerhead structure in avocado sunblotch viroid (ASBV), showing that the shorter RNA molecule consisting of only 19 nucleotides would cleave its longer companion at the place predicted by what happens in ASBV itself (see Fig. 4).

That neat demonstration is likely to play an important part in the resolution of the status of the US and Australian patent applications, as the news report of the 12 October explained. Uhlenbeck's 19-nucleotide RNA is a true ribozyme, catalysing the cleavage of more than one molecule of its substrate. On the face of things, it appears also to be a particular example of the class of ribozymes at the core of the Australian patent application, which had not then been lodged. Although Uhlenbeck has not applied for a patent, and does not intend to do so (even under US law, he would be out of time), the publication of his paper may be held to invalidate later applications for patents covering ribozymes of similar design, or even to show that developments such as these were, by mid-1987, "obvious" in the sense in which patent law uses that term.

CSIRO's application

The Australian patent application, first lodged with the Australian Patent Office on 15 December 1987, is a model of clarity in such complicated circumstances. Observing that self-cleavage sites have been recognized in several plant viruses and related RNA, the document goes on to suggest a means by which efficient ribozymes may be constructed from synthetic RNA by an elaboration of the hammerhead principle.

Indeed, its authors generalize what is known of the common nucleotide structure of self-cleaving RNA molecules. Their claim rests on the assertion that ribozymes of any pre-determined specificity may be constructed by synthesizing RNA molecules in which the active cleavage element of the ribozyme is surrounded by short stretches of RNA capable of attaching, by Watson–Crick complementarity, to RNA sequences on either side of the desired cleavage site in the substrate RNA molecule (see Fig. 5). The essential elements of the patent application have been published (W. L. Gerlach and J. P. Haseloff, *Nature*).

Significantly, the Australian patent application (PCT/AU88/00478, published as WO89/05852) acknowledges Cech's earlier work and the existence of his patent application, but asserts that the two sets of ribozymes are distinct. First, the Australian application says, Cech's ribozyme occurs naturally in *Tetrahymena thermophila*. But the argument continues that Cech's ribozymes require the presence of guanine or one of its derivatives (usually GTP), add this nucleotide to the upstream end of the downstream cleaved fragment and holds that the Cech ribozyme is likely to be less specific than the Australian because fewer nucleotides can be involved in the hybridization of the ribozyme and its substrate molecule, especially because some of the crucial nucleotides cannot apparently be changed. The result, the Australian application says, is further to restrict the freedom to engineer specificity.

The Australian patent application is also more specific about the applications foreseen for artificial ribozymes than are Cech, Zaug and Been. In that document, the only use of ribozymes explicitly described is as laboratory reagents. But the Australian patent application says that ribozymes can be engineered to cleave any RNA molecule at a pre-determined sequence of ribonucleotides, meaning that target RNA sequences can be made inactive. Alternatively, as the case is put, ribozymes might be produced endogenously in cells by the transfer of self-replicating plasmids or by microinjection.

The application says explicitly that infectious mammalian viruses might be inactivated by the direct administration of appropriate ribozymes or by incorporating into vectors such as vaccinia virus carrying sequences of DNA, that would allow the production of the ribozymes endogenously. The same (the application says) could be done to neutralize the effects of unwanted gene activity in plants, even to the extent of engineering plants that produce fruit without stones, as well as to treat genetic disease in people where the underlying defect is the overproduction of a protein produced at the prompting of some mRNA.

Nobody can cavil at the importance of these claims. If CSIRO and its commercial partners — CSIRO hopes there will be an Australian partner as well as the French company Groupe Limagrain — can find a way of delivering specific ribozymes into misfunctioning cells, they will have found a way of curing many of the world's ills. There may be practical difficulties to be overcome before engineered ribozymes can be used as medicines, and regulatory hurdles to be surmounted before vaccinia virus and other genetic vectors can be used in the prophylaxis of human disease, but CSIRO's enthusiasm for its "gene shears" process should not be crabbed.

Disputations

Nobody, unfortunately, can tell in advance how patent lawyers and (if it comes to that) the courts will determine the relative merits of these rival, but not necessarily conflicting, claims. Cech, Zaug and Been were first, by more than two years, but Gerlach, Haseloff and Jennings describe what appears to be a more efficient ribozyme, and one whose specificity may be pre-determined by a knowledge of the nucleotide sequence of the RNA it is meant to cleave, irrespective of its source.

Variations of patent law from one country to another will complicate the resolution of the issue; for example, patents might be awarded in the United States to both applicants, but to one or other elsewhere. On the face of things, the existence of independent prior publications, such as those of the Symons group and particularly of Uhlenbeck, would seem to be an embarrassment for CSIRO's case. On one view, the commercial value of CSIRO's gene shears technique may hang on the speed with which the organization is able to work towards its practical exploitation.

How did *Nature* come to be calling the odds on such a complicated issue in its news report of 12 October? It made mistakes, listed in what follows, in incompletely extenuating circumstances.

One error was that of CSIRO, which first annouced at the end of July this year that it had signed an agreement with Groupe Limagrain for the exploitation of its "patent" on gene shears. If that claim had been less definite (only an application for a patent had then been lodged), *Nature*'s informants in the United States might have been less eager to say that something must be wrong. The outcome was a conversation with the Boston-based patent attorneys acting for US Biochemicals Corporation, which has acquired rights to exploit the Cech, Zaug and Been patent.

Six weeks went by before *Nature*'s Australia correspondent, Tania Ewing, who had by then spoken to the US patent attorneys, approached Dr Jim Peacock, at the Plant Industries Division of CSIRO, telling him at the outset only that doubts had been cast on CSIRO's announcement in July, but in later conversations asking for his reaction to the US claims that the Cech patent application had precedence over whatever might be claimed in Australia. The response appears to have been unspecific; detailed discussion was declined, but Dr Peacock and other members of the gene shears team insisted that they were "confident" that their patent application would succeed, pleading CSIRO's patent lawyers in their support. But access to the lawyers was denied, on the grounds that "that is not CSIRO policy".

The contemporary sociology of Australia is relevant. The country is lavishly over-governed, but the press is constitutionally powerful; public officials who refuse to answer questions on the telephone may be lampooned. Meanwhile, CSIRO has made a painful transition from semi-autonomous research organization to government agency of a kind; the pressure to succeed commercially is intense and insistent, as is the fear of failing to succeed. So researchers dutifully answer the telephone, even returning calls from journalists, but deal cautiously with questions of a kind that politicians might understand.

If Tania Ewing had been offered a sight of the two disputed patent applications, she would not have concluded that her US patent attorney informants were correct in their assertion that the Cech patent would supervene and that CSIRO's confidence was misplaced; instead, she would probably have decided that there is a tangled fight ahead. Yet even two weeks ago, CSIRO was still saying that it would be possible to secure a copy of the Cech patent application only from the International Patent Office at Geneva, its own complement of photocopying machines notwithstanding.

Those, so far as *Nature* is concerned, are most of the extenuating circumstances. Three errors in the 12 October account stand out, as follows:

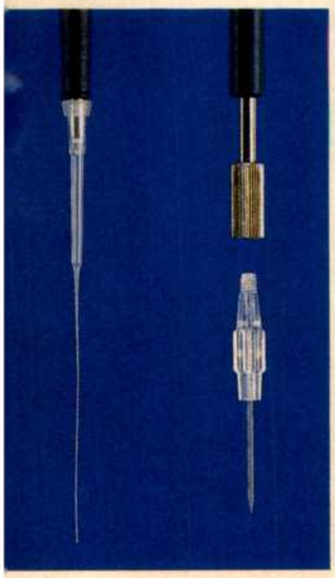
- Dr Jim Peacock was at one stage asked whether he "remembered a letter from a man called Jim Chen", allegedly a discouraging report on the Australian patent application from the Australian Patent Office. But in reality, the document concerned was not a letter but a standard form report (citing the Uhlenbeck research as potentially prior art), with Jim Chen's signature in the bottom right-hand corner, Peacock had indeed forgotten (if he had ever remembered) that the form had been signed by Chen. When reported to have "forgotten," the results of this international patent search, he was made to look a fool. He was, of course, fully aware that he had received the research report.

ECET Femtotip®

The tip-top standard capillary

Our tip for microinjection

The ECET Femtotip has the op form for microinjection. The design and outlet iameter (0.5 ± 0.2 µm) of this standard capillary are ptimized for accurate micro-njection in tissue culture ells. You can start micro-njection at any time. The azard of blockages is educed to a minimum with ppendorf's precisely designed Femtotips.



Eppendorf -

Teletex no. 40 30 61 = EGHAM
Telefax (0 40) 5 38 01 556

Simplified operation

With the aid of the Eppendorf Microloader, all capillaries can be filled with filament. The Microloader is a very finely pulled pipette tip that fits Eppendorf Pipettes 4700 and 4710. It places the liquid to be injected near to the capillary tip. By keeping the path of the injection liquid to the capillary tip as short as possible, you minimize adsorption, aggregation and concentration effects. Therefore, you can even handle smallest volumes with outstanding precision.

Repligen IPA-300: The Protein A that gets there on time

Now you don't have to face any order backlog for the Protein A you need tomorrow. Repligen delivers ultrapure and immobilized rProtein A when you need it. You can get 2 milliliters or 2 liters of IPA-300 shipped today. And Repligen also guarantees high binding and virtually no leakage to the toughest specifications in the industry. That means IPA-300 delivers the consistent purity you need for single pass purification of therapeutic grade monoclonal antibodies. Plus our FDA Drug Master File provides full documentation to speed the preparation of your IND submission. Call today for the Protein A that gets there on time and saves you time. Repligen's IPA-300.*

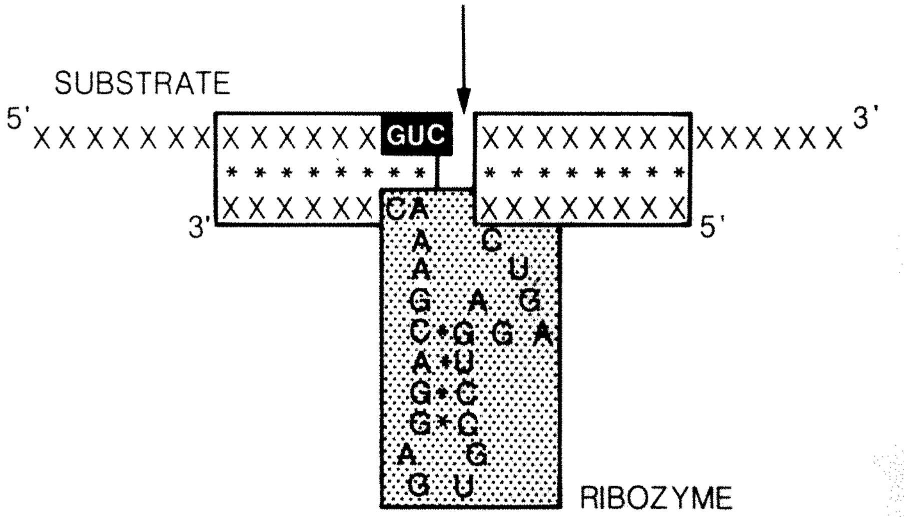

FIG. 5 The CSIRO ribozyme. Schematic diagram (from the Australian patent application) in which X stands for any nucleotide and X.X for any (or either) pair of complementary nucleotides. The shaded block includes the shortest RNA sequence found to be effective in cleaving RNA parasitic on plant cells. As shown, the ribozyme would cut the upper substrate RNA strand after the nucleotide triplet GUC, but the patent application argues that this restriction may be relaxed so long as the central nucleotide in the triplet remains as uracil and so long as the third is not guanine. The RNA sequences attached to the common ribozymal unit would be synthesized so as to be complementary in sequence to the naturally occurring substrate and thereby enhance the specificity of the ribozyme.

■ In the same vein, Mr Stephen Castle at the Australian Patent Office was quoted directly as saying "We don't think they [CSIRO] will get their patent". There is a direct conflict of evidence on this point between what Mr Castle says occurred and Tania Ewing's notebook. Mr Castle says that on the day Ms Ewing reached him by telephone, he was standing in for his immediate supervisor, Jim Chen. The question was whether the "X" rating in respect of Uhlenbeck's paper would be fatal for CSIRO's application. Mr Chen says that he explained he had no direct knowledge of the application, that he explained that he could not discuss particular applications, but recalls saying that such an annotation "means that a patent will probably not be granted". At an interview conducted in the presence of Mr Murray Heddrich, Deputy Commissioner of the Patents Office, Mr Castle also says that he explained that an "X" document would invalidate only the particular claims to which the annotation referred (a third of the total in the case of the Australian patent application) and that applicants might in any case successfully challenge the examiner's judgement.

There is no simple way in which such a conflict between written and remembered evidence can be reconciled. But it can be understood. In Ms. Ewing's notebook, the quotation "We don't think they'll get their patent" follows directly after a notation of a question about Uhlenbeck's article, implying that the two questions were closely linked. Mr Castle's recollection is that they were widely separated. Whatever the intervening material, it goes without saying that anybody hearing the phrase "We don't think they'll get their patent", even if in response to a question about the general significance of "X" ratings, would have concluded that what applies to the general also applies to the particular, only recently discussed. But Mr Castle's reservations, however emphasised during that conversation still apply: prior publications threaten only the claims to which they are judged relevant, and that judgement may always be challenged. The moral seems to be that, when writing about patent applications, it is important to read them (if you can get hold of them).

■ In the United States and Western Europe, *Nature* distributes each week to interested journalists a summary of each week's scientific content, regretting that the timing of this operation is such that important items of news cannot be thus advertised. On this occasion, it was agreed between Sydney and Washington that advance notice of the news report of the gene shears patent should be distributed to a few Australian journalists, which had the unfortunate effect of amplifying the misleading aspects of the news report.

The first of these issues is a misunderstanding, the second a potential misunderstanding, the third is an error of judgement. *Nature* is sorry for the hurt they may have caused, however trying the circumstances. But it is hard to fathom the ferocity of the Australian reaction. Mr Barry Jones, the federal Minister of Science, telephoned Ms Ewing on the afternoon of 19 October to say that the Australian government would sue her and *Nature* for what she had written, which information was the basis for at least two daily newspaper reports the following day. Two weeks ago, Mr Jones rejected the charge that he was seeking to intimidate journalists, but could not recall the circumstances in which he had made the call.

Nature has the fullest confidence in its Australia correspondent and hopes to be able to do so for many years. There are nevertheless several lessons to be learned from this saga, as much by people in offices in Washington and London as by reporters in the field. One is the old journalistic saw that one cannot be too careful — of volunteered information (although, without it, journalism would grind to a halt), of the contents of documents which have not been read, but only reported by potentially interested parties, and of the difficulties of pursuing information on two continents which are separated by 16 hours on the clock. On this occasion, proper scepticism of Australian claims seems to have been unfairly magnified.

The plain truth is that the Gerlach and Haseloff design for ribozymes is certain to be widely applied in the laboratory processing of RNA, while the potential of the applications in medicine and agriculture is potentially very great. Before these prizes can be won, of course, several less interesting practical problems will have to be solved. Using ribozymes as medicines for the treatment of AIDS, for example, will require that means of delivering effective doses of the material to infected lymphocytes will have to be found. By all accounts, the pharmaceutical companies are not amused.

Yet Peacock says that the collaboration with Groupe Limagrain has already embarked on two development projects with promise. It would be good to think that Australia will yet win a good share of the benefits seemingly in sight. The pressure exerted by the federal government in such directions may often be over-onerous or even short-sighted, but it has been Australia's dream for several decades to supplement its staple exports of primary products from mines and farms with exports whose added value is greater. That, of course, is why neat gene shears were so generally acclaimed in July this year.

The question whether interesting science is now too much confused with the patents business is a perennial question but also often an academic one. For many people there is often no choice. Protecting intellectual property has become part of research, even survival in research. Yet the task of briefing patent attorneys is an irksome and time-consuming obligation from which some people still shrink. A predictable but unexpected consequence is the effect of the patents business on people's demeanour. Much of the reticence encountered in describing CSIRO's gene shears seems to have arisen both from unfamiliarity with arcane patents practices and from the way in which attorneys frequently swear their clients to silence. Too much of that could bring great trouble. □

VOLCANOES

Magma transport through dykes

Greg A. Valentine

THE transport of magma through the Earth's crust, whether from relatively shallow magma reservoirs (depths of a few kilometres) or the upper mantle (depths approaching 100 km) has always presented geologists with a challenging problem. Much of the challenge arises from the complex behaviour of magmas under conditions of changing temperature, pressure and composition. An important aspect of magma flow through fissures is the exchange of heat with the surrounding rocks. For flow to be sustained, the heat advected from the magma reservoir must successfully compete with the loss of heat to the cooler country rocks. This competition leads to a physical system in which hydrodynamics (the advection of heat) and thermodynamics (latent heat from solidification and diffusion of heat into surrounding rocks) are strongly coupled and cannot be treated as independent processes. In an important new analysis, Bruce and Huppert show on page 665 of this issue[1] how the coupling can lead to complex processes of solidification followed by re-melting. They derived a criterion that separates dyke blockage by solidification from sustained flow.

A typical basaltic fissure eruption, on Mauna Ulu, Hawaii, 1969, showing fire-fountaining due to eruption of gas-rich magma. These eruptions commonly occur along an entire fissure during initial phases, but eventually become localized to a few discrete vents along the fissure. According to Bruce and Huppert[1] this trend may be the result of extreme sensitivity of magma flow in fissures to the initial width of the fissure. Small irregularities in the initial width may become pronounced as an eruption progresses, leading to concentration of magma discharge in slightly wider parts of the fissure. (Photograph by W.A. Duffield, US Geological Survey.)

Field evidence shows that magma is transported through the crust mainly by the flow of magma through cracks, or dykes. Hence, dykes are a significant feature in nearly all magmatic provinces of all ages, especially where mafic or ultramafic (iron- and magnesium-rich) magmas are present. In areas undergoing tectonic extension, such as mid-ocean ridges and continental rifts, the dominant means of magma transport to the surface is within dykes. Oceanic islands within tectonic plates, such as Hawaii, are characterized by large, low-relief shield volcanoes that erupt magmas from linear fissures on their summits and flanks (see figure); these fissures are the surface expression of dykes. Even silicic magmas are commonly influenced by flow in dykes at some level in the crust. Examples of this include dykes that radiate out from central conduits of stratovolcanoes, linear sytems of silicic domes and ring dykes associated with large intrusions.

Magma transport via dykes presents two problems which can, to some extent, be treated separately. The first is formation of the crack. In many cases the initial crack may be a pre-existing fracture in the host rock, but in others the fracture is probably propagated by the magma itself in a manner similar to hydrofracture processes. This magma-fracture process has been studied by Spence and Turcotte[2] for highly simplified cases that can be mathematically analysed by a similarity solution. They find that magma can propagate fractures in a vertical direction at speeds of the order of $0.01-100\ \mathrm{m\ s^{-1}}$, the buoyancy of the magma driving them upward. Their conclusion is that most of the transport problem resides in the flow of magma once the fracture has opened; the initial fracturing itself is not, in general, a limiting process.

The fluid-flow problem is more daunting owing to the nature of magmas. The rheology of magma is strongly dependent upon its composition. Viscosity, for example, can vary over several orders of magnitude for a change in SiO_2 content of just 20 per cent. Furthermore, at any given composition, the viscosity depends on the temperature and strain rate. As a magma cools or heats, it can undergo drastic phase changes that modify the behaviour of the fluid and that involve significant exchanges of latent heat. Previous treatments of magma cooling due to heat loss to the dyke walls have consisted of simple static conduction calculations[3], empirical calculations of heat exchange between flowing fluid and a wall for one-dimensional flow[4], and two-dimensional calculations allowing for some advective effects[5]. None of these formally allowed for the effects of latent heat released or absorbed by material as it solidifies or melts, respectively.

Bruce and Huppert[1] make an important step in the theoretical treatment of magma flow in dykes by allowing the advection of heat by flowing magma to affect the temperature distribution in the wall rock. They include melting, solidification and related latent-heat effects in their analysis. Two important regimes are found: one in which heat loss to the walls exceeds heat advection and the dyke freezes shut; and a second in which initial heat loss may exceed advection, but in which advection and latent heat effects eventually win and the dyke remains open and may even grow wider. This second regime involves initial solidification of magma along the walls followed by re-melting (meltback).

Bruce and Huppert's calculations have a wealth of implications for eruption dynamics and petrological variations of eruptions from fissures. For example, the sequence of initial solidification followed by meltback could strongly influence eruption dynamics. The solidification would concentrate volatiles into the remaining melt in a dyke, which upon eruption may appear to be 'artificially' volatile rich. In a basaltic fire-fountain eruption, this partitioning of volatiles may lead to a higher fountain, which would in turn lead to overestimates of the volatile content in the magma chamber. Later, as meltback occurs, volatile-depleted material (the old chilled margin) would be mixed up with the flowing magma to deplete the eruptive mixture 'artificially'. Such events could produce apparent variations in original magma composition, even if the original composition was unzoned. Is it possible that this process is responsible for fluctuations in fountain heights during eruptions such as observed by Head and Wilson[6]?

These processes could also influence the major- and trace-element composition of erupting magmas, which should be altered to some degree by the solidification–meltback process, especially if meltback reaches past the original dyke walls and involves original country rock. Also, they are likely to produce nonequilibrium textures in phenocrysts.

It seems essential to collect samples of basalts as they erupt from a given vent, in order to observe some of the processes that Bruce and Huppert predict, as cooled dykes are highly unlikely to preserve these processes. A difficulty arises because the original compositional zonation in the magma reservoir and the effects of draw-up into the dyke would have to be established independently of the basalt sampling — a challenging prospect.

Finally, it is worth noting that even though Bruce and Huppert's analysis is an important step in elucidating magma transport in dykes, we are still a long way from a physically complete understanding of the process. For example, none of the analyses mentioned above, including Bruce and Huppert's, takes into account the real rheology of magmas. In addition, multiphase flows[7] that result from the release of dissolved gas from the magma need to be incorporated into the heat-transfer problem. Neglect of these processes is attributable partly to poor data on magma properties, but also to limitations in mathematical approaches that rely mainly on analytical techniques. Numerical solutions of the full set of governing equations with minimal simplifications would constitute a significant advance. ☐

Greg A. Valentine is in the Geoanalysis Group, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA.

CELL BIOLOGY

The pushy ways of a parasite

John E. Donelson and Alice B. Fulton

A SERIES of electron micrographs in the *Journal of Cell Biology*[1] provides new insight into how an intracellular bacterial parasite, *Listeria monocytogenes*, behaves inside cultured macrophages and how it moves from one macrophage to another without ever leaving the cytoplasm. The authors of the paper, Tilney and Portnoy, not only demonstrate the cunning way in which the parasite traverses the perilous divide between host cells, but provide pointers to fresh approaches for studying the cytoskeleton.

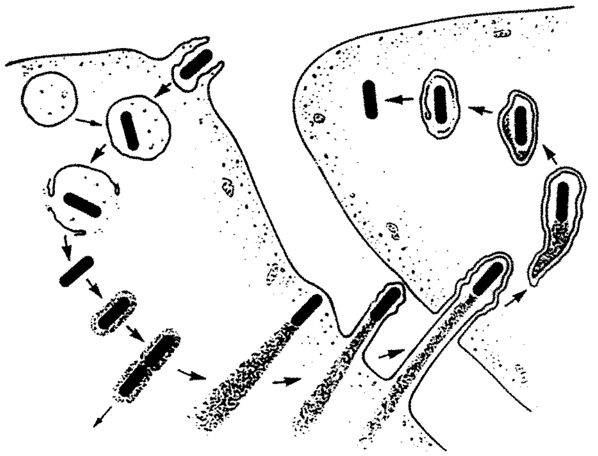
All parasites of mammals must evade the immune systems of their hosts. Some do it by hiding within host cells, but this strategy has its own complications as the insides of host cells can be distinctly hostile[2]. Parasites that survive within host cells such as macrophages have therefore evolved a variety of mechanisms to prevent themselves from being destroyed by cellular defences such as lysosomal acid hydrolases and the oxidative response. For example, some intracellular parasites inhibit fusion between the parasite-containing phagosome and lysosomes *(Toxoplasma, Chlamydia);* others are resistant to lysis by lysosomal enzymes (*Leishmania*, mycobacteria); and still others escape from the acidic 'phagolysosome' into the host cell's cytoplasm *(Listeria, Trypanosoma cruzi)*[3]. But even after coping with the host cell's defences, the parasite must still avoid destruction by the humoral immune system during transfer from one cell to another.

Listeria monocytogenes is a gram-positive, non-spore-forming pathogen of humans, sometimes found in unpasteurized milk, that penetrates macrophages, fibroblasts and enterocytes. Following phagocytosis, the parasite-containing endosome fuses with one or more lysosomes (see figure). Tilney and Portnoy's electron micrographs show that the phagolysosome membrane dissolves before the bacterium is damaged; the membrane is probably degraded by a bacteria-encoded haemolysin, because *Listeria* mutants lacking haemolysin fail to escape from the phagolysosome[4].

After phagolysosome breakdown, the *Listeria* subverts the macrophage's cytoskeleton for its own purposes in an unexpected way. First, a halo of actin filaments (which are decorated by myosin subfragment-1) surrounds the bacterium. After the *Listeria* divides, this halo becomes asymmetric, forming a tail at one end of the bacterium and taking on the appearance of a short comet. The halo and comet tail are densely packed with short randomly ordered filaments. As the tail elongates, the bacterium is apparently 'pushed' by the comet tail towards the macrophage surface. Once at the surface, the *Listeria* distends the host membrane to form a pseudopod-like extension that touches another macrophage. The *Listeria* and some of the actin tail are engulfed by the new host cell and another round of infection begins. Thus, once safely inside the first macrophage, the *Listeria* need not confront the perils of the humoral immune system again.

This exploitation of the host's cytoskeleton raises several questions. First, how does the *Listeria* induce the macrophage's actin to polymerize? The halo and comet tail are not simply pre-existing filaments recruited into these structures, because cytochalasin D prevents their formation and stops the bacterium from moving towards the surface. The filaments appear to grow from some component of extracellular material around the *Listeria* as all the filaments begin near the bacterial surface. *Listeria* has recently been found to export a basic (isoelectric point 9.3) protein of relative molecular mass 60,000 involved in bacterial attachment to the host cell[5]; perhaps this positively charged protein also nucleates actin polymerization in the host cytoplasm, as does polylysine *in vitro*[6].

Second, why are these particular filaments so short, skewed and stable? Their average length appears to be only a few tenths of a micrometre, yet the comet tail of several micrometres is stable for up to an hour. Does *Listeria* secrete a toxin, such as



Steps in the entry, multiplication, movement and transfer of *Listeria* from one macrophage to another. Once inside a macrophage the bacterium escapes into the host's cytoplasm and is surrounded by a halo of the host's actin. After division, the actin around the daughter bacterium becomes asymmetric, taking on the appearance of a comet. As the tail elongates, the bacterium is apparently propelled towards the macrophage membrane, where a pseudopod-like extension of the cell membrane is formed. When the pseudopod is engulfed by another macrophage, the bacterium is released into its new host cell.

phalloidin, that stabilizes filaments? If so, how does the rest of the actin in the cell escape its effects? Why is the long comet tail composed of these short, skewed filaments when normal elongated actin structures generally have longitudinal order, sometimes approaching a paracrystalline state? Does *Listeria* secrete a bundling protein to hold together the short, skewed filaments, or does it recruit one from the host?

Perhaps the simplest explanation is that *Listeria* has many high-affinity nucleation sites for actin polymerization on its surface. The progeny bacterium appears to have fewer sites at one end so that actin polymerization imparts motion to the bacterium by mechanically pushing it. Actin polymerization is known to be involved in pushing out the membrane of the acrosomal process of *Thyone briareus* sperm[7].

Regardless of the mechanism underlying the bacterium's movement, how it becomes directed towards the macrophage surface remains unexplained. However, if the nucleating component is shed by the bacterium as it moves, the filaments would be left behind in the tail. The apparent stability of the filaments may be a consequence of their exceedingly high density and the presence of the nucleating component. Their disarray may reflect the absence of crosslinking proteins.

At least some of these questions can be addressed at the genetic level because transposon mutagenesis and plasmid DNA transformation can be carried out with *Listeria*[8]. Furthermore, cytoskeletal subversion may be a common tactic used by other intracellular parasites. Intracellular infections by bacterial and protozoan parasites have long been used as models for studying cell-mediated immunity — Tilney and Portnoy's findings indicate that they are also good systems for examining cytoskeletal formation, organization and function. ☐

PALAEOCLIMATE

Deep trouble for climate change

N.J. Shackleton

THE search for geological evidence of past climate changes has yielded much material for modellers trying to understand the principal factors controlling these changes, be they variations in the ocean–atmosphere system or slow changes in the Earth's orbit as suggested by Milankovitch. New data derived from the ages of fossil corals, presented by Fairbanks on page 637 of this issue[1], show that we still do not understand the very rapid change in climate during the period known as the Younger Dryas at the end of the last glaciation.

The fossil coral terraces of tropical islands provided the first convincing geochronological evidence that the Milankovitch hypothesis of long-period climate forcing might be correct[2]. The uplifted coral tracts have yielded extremely valuable data on the history of climate-induced changes in sea level[3,4]. Coral deposited over the past few thousand years has also been dated for reconstructions of the approach of sea level to its present position as the ice sheets of the last glacial maximum finally faded away[5]. By drilling into the uplifted interglacial terraces in Barbados, Fairbanks and Matthews[6] were able to document on the ground the relationship between the changing isotope composition of the oceans as ice sheets melted and grew, and the height of the sea relative to Barbados.

Despite these contributions, there has been a fundamental difficulty in interpreting the ocean oxygen-isotope record — a key to so many aspects of palaeoclimatology — because we have had no means of accurately comparing ^{18}O and ice volume, or sea level, over the whole glacial–interglacial range[7]. Armed with his experience of the uplifted coral terraces, Fairbanks has now filled in much of this gap in our understanding by taking a look at the submerged coral, which one had always suspected must be there awaiting attention. In this issue[1] he shows the first, exciting results of that enterprise.

What Fairbanks has done is to drill and core submerged coral at depths below sea level ranging from 10 m to about 130 m. Concentrating on *Acropora palmata*, which grows only within about 5 m of the sea surface, he has obtained the ^{14}C age and present depth of each piece. Correcting this depth for the slight uplift of the island over the past 15,000 years he obtains the first almost continuous record of sea-level rise during deglaciation (even a single well-dated estimate of the glacial low-stand would have justified publication).

Still more exciting is the fact tha Fairbanks's temporal cover is good enoug for him to differentiate the sea-level curv to present a direct measure of the rate o rise of sea level, which is of course equivalent to a measure of the meltwater flu into the oceans. As Fairbanks points out this will be subject to some subtle modification when we have a more accurat knowledge of the relation between so-called 'radiocarbon years' and true years However, his conclusions, even as the stand, call into question a recent interpretation of the Younger Dryas event.

The Younger Dryas event was an interva lasting a few centuries between 11,000 an 10,000 years before present (BP) durin which the climate of northwest Europe which had been quickly improving afte the glacial maximum, was suddenly throw back to near-glacial levels. Glacier advanced again, an event marked as the Loch Lomond Stadial in Britain. The reason for this event has intrigued people for many years; one reason for devoting special attention to it is that whereas the growth of the great ice sheets took place over thousands of years, this event appears to testify to the ability of the global climate system to shift from an interglacial to a glacial state in a matter of decades. Is global climate balanced so finely that it could flip easily into a glacial mode?

In a series of papers[8,9], Broecker has argued that the Younger Dryas may have been a feature peculiar to the deglaciation period rather than something that could happen at any time. He recently demonstrated[8] that the Younger Dryas occurred between two periods during which glacial meltwater flooded down the Mississippi river to the Gulf of Mexico, as indicated in cores recovered from the Orca Basin. Broecker's argument is that, between these two events, meltwater was diverted and instead entered the ocean so far north that it upset the density stratification of the North Atlantic.

His reasoning is that such a huge meltwater influx down the Saint Lawrence Seaway would significantly lower the salinity of the surface of the whole northern part of the North Atlantic. This would prevent the winter cooling of the sea surface in the Norwegian and Labrador Seas from raising the density of the water enough that it could sink to form the North Atlantic Deep Water. Broecker's underlying hypothesis[9] is that the global climate system has two stable states, a glacial state and an interglacial state, and that upsetting deep-water formation in the North Atlantic is a mechanism for flipping the system into the glacial state. In this picture, the Younger Dryas would be such a flip into the glacial state that arose as a chance by-product of the geographically complex melting history of the North American ice sheet.

Fairbanks's work shows that, in fact, melting almost stopped during the Younger Dryas, the meltwater flux fell to a fifth of the maximum value it had had a millennium previously The peak flux was at 12,000 years BP, identical in age with the greatest Mississippi flow[8] By 11,000 years BP, the rate of sea-level rise was at a minimum, the same date as the cessation of enhanced Mississippi flow Fairbanks's data show that the pulse of very rapid melting came to an end shortly after 12,000 BP, it would be very difficult now to argue that the diversion of the Mississippi flow could have been the main trigger for this important climatic episode, and it seems likely that the whole edifice that Broecker elegantly erected to explain it has collapsed like a house of cards At the same time the climatic importance of the event seems to be reinforced, as it did, indeed, almost totally halt the dramatic retreat of the great ice sheets Doubtless Broecker will reconstruct his hypothesis even more elegantly in his next contribution □

MHC PROTEIN STRUCTURE

Getting into the groove

Peter Parham

In October 1968, purified papain-solubilized HLA-A2 made its debut in the pages of *Nature*[1], nineteen years later the crystallographic structure of this human class I major histocompatibility complex (MHC) molecule provided dramatic insights into T-cell biology and laid the ground rules for future experiments and speculation[2,3] Perhaps of greatest impact was the 'extra electron density' on display — the hazy, ill-defined image of something filling the binding site, with far-reaching implications for antigen presentation, MHC restriction and T-cell tolerance From the genetic perspective it was their diversity and polymorphism that drew attention to MHC proteins, and although modelling of many MHC sequences into the A2 structure indicated that residues lining the sides and floor of the peptide-binding groove were the foci for advantageous amino-acid substitution[2–4], little was revealed of the architectural details resulting from this diversification of the antigen recognition site With refinement of HLA-A2 and solution of the structure of HLA-Aw68, Garrett *et al* [5] now begin to provide such insight on page 692 of this issue they guide us through the interstices of the celebrated 'groove', and in so doing complete what is arguably the first crystallographic experiment in MHC genetics

Polymorphic pockets for peptides. It is the extracellular region of class I molecules that binds peptides, T-cell receptors and either the CD4 or CD8 coreceptor[6] These molecules consist of two immunoglobulin domains and two 'peptide-binding' domains For HLA-A2, HLA-Aw68 and other class I MHC molecules, the polymorphic and membrane-anchoring heavy chain contains both peptide-binding domains (α_1 and α_2) and one immunoglobulin domain (α_3), while a second, and in humans invariant, polypeptide (β_2-microglobulin) provides the second immunoglobulin domain[2] In contrast, class II molecules have a symmetrical, and probably more ancient, arrangement in which two membrane-spanning polypeptides each contributes one peptide-binding and one immunoglobulin domain

With minor perturbations, the polypeptide backbones of HLA-A2 and HLA-Aw68 are extremely similar[5] This greatly simplifies comparison of the two structures for the differences between them are primarily due to the nature of amino-acid side chains at 13 positions (six in α_1, six in α_2 and one in α_3) of substitution in the heavy-chain sequences (Fig 1*a*) Ten of these residues are at positions lining the floor and sides of Garrett's groove and the differences in their chemistry, size and polarity have profound effects on its contours and on the peptides that bind, as is vividly shown by differences in the extra electron density of the two crystals

Although the antigen-recognition site (α_1 plus α_2) is symmetrical, the disposition of substitutions between A2 and Aw68 is not A 'boomerang' pattern of variation, extending along the α_1 helix and then traversing the β structure of α_2 to the centre of the α_2 helix (Fig 1*b*), is in fact similar to the distribution of high-variability residues obtained from accumulated HLA-A,B,C sequences[7] The reason for such segregation of variation and conservation within the binding groove is not discerned by Garrett *et al* [5]

b

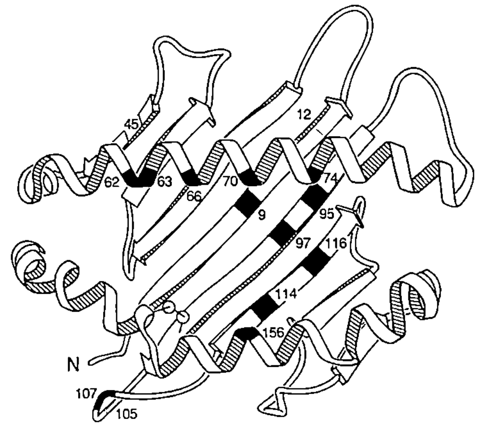

FIG 1 *a*, Amino-acid substitutions between A2, Aw68 and related molecules Sequences are compared to Aw68 1 and only positions of difference are shown identities with Aw68 1 are given by lines The ten substitutions between A2 1 and Aw68 1 that line the peptide-binding groove are indicated by (▼) and the substitution at 62 that is hypothesized to affect T-cell receptor contacts is given by (▲) Residues affecting the 74 pocket are indicated by (Δ) Charged residues are noted by plus or minus Histidines, a characteristic of A2, are indicated with (+) as their protonation under physiological conditions is uncertain

The nomenclature for human class I MHC molecules is confusing because names have traditionally been given on the basis of serological reactivities which often encompass the products of more than one allele Thus serologically defined HLA-A2 is known to include at least nine distinct proteins of which the 'A2' structure[2,3] derives from HLA-A2 1 Serologically defined HLA-A28 was initially divided into HLA-Aw68 and HLA-Aw69, and subsequently HLA-Aw68 into HLA-Aw68 1 and Aw68 2 (Garrett *et al* 's structure is of Aw68 1) Revision of nomenclature in terms of sequence is fortunately in progress

b, Schematic representation of the α_1 and α_2 domains of the HLA-A structure showing the 'boomerang' pattern of substitutions Differences between A2 1 and Aw68 1 are shaded solid, substitutions specific to Aw68 2 are shaded with stipple Position 45, which is invariant in HLA-A sequences and contributes to the conserved 45 pocket, is also shown (Adapted from Fig 2 of Bjorkman *et al* [2])

HIGH-ENERGY PHYSICS

The Big Bang's magic number

Frank Close

INITIAL data from the LEP electron–positron collider at CERN, Geneva, now formally published in *Physics Letters*[1-4] confirm one of the cornerstones of modern physics, namely the Big Bang model for creation of matter

The Big Bang model rests, in large part, on the ability of theory to explain the relative abundances of the light elements, in particular the primaeval ratio of hydrogen to helium The fusing of these light elements took place during a brief interval in the early Universe Before this time the heat was too great for the nuclei to stay bound, beyond this time free neutrons had decayed and were no longer available for the alchemy The elemental abundances depend, *inter alia,* on the amount of time the Universe spent in these judicious conditions, which depends on its rate of expansion and this, in turn, depends on the number of light particle varieties around — hence on the number of light neutrinos Cosmologists had thereby determined that they could explain the elemental abundances if there were at most four varieties, or 'flavours', of light neutrino, where light means less than about 1 MeV (that is less than about twice the mass of the electron)

The LEP results reveal the number of light neutrinos directly, without any assumptions about elemental abundances or cosmology The essential key is that counter-rotating beams of electrons (e^-) and positrons (e^+) annihilate at an energy tuned such that they produce the massive Z^0 — the carrier of the neutral weak interaction Among the various decay pathways for the Z^0 are pairs of neutrinos (precisely, a neutrino and an antineutrino) Thus, just as water escapes from a leaky bucket faster the more holes there are, so the lifetime of the Z^0 is shorter the more neutrino flavours there are for it to decay into It is the precise measure of this lifetime that has determined the number (N_ν) of light neutrino flavours

The quality of the LEP results may be illustrated by comparison with previous knowledge on N_ν C Hearty *et al*[5] analysed lower-energy data on $e^-e^+ \rightarrow$ a photon (γ) + missing neutral energy If the missing neutral energy is carried by neutrinos, this gives $N_\nu < 5\ 2$ In that same paper, the analysis of W and Z^0 production and decay data at CERN's older proton–antiproton collider gives $N_\nu < 7\ 0$ for the UA1 and UA2 collaborations individually (though this involves further information from other processes and is thus somewhat indirect) The analogous Z^0 production at the Fermilab Tevatron hadron collider was studied by the CDF collaboration[6], this gives a rather good measure of the Z^0 mass but does not significantly limit N_ν

The significant advances have come from the custom-designed electron–positron machines SLC (Stanford Linear Collider) and LEP The SLC uses new concepts in collider technology and is currently accumulating data slowly Their results are limited by the statistics, their original publication (cited in David Miller's News and Views[7]) gave $N_\nu = 3\ 8 \pm 1\ 4$, by the time of the Stanford Lepton–Photon Symposium in August this had improved to $3\ 0 \pm 0\ 9$ and the latest refinement[8] is to $2\ 8 \pm 0\ 6$

LEP is a conventional circular collider that has performed to design specification in a miracle of technological success The four large collaborations have made their first reports on the Z^0 parameters and obtain for $N_\nu = 3\ 42 \pm 0\ 48$ (L3[1]), $3\ 27 \pm 0\ 30$ (ALEPH[2]), $3\ 12 \pm 0\ 42$ (OPAL[3]) and $2\ 4 \pm 0\ 65$ (DELPHI[4]) Thus the odds against even four flavours are drastically lengthened and the three known may be the sum total Moreover, cosmologists defined 'light' as a mass below 1 MeV, the SLC and LEP data extend this by a factor of 40,000 to below 40 GeV

The Z^0 decays to hadrons and charged leptons as well as to neutrinos so the neutrino decays are only a part of the whole, which limits the accuracy of deduction of N_ν The best bet for improving the limits on N_ν seems to be LEP, where the machine works so well that good statistics may be anticipated for $e^+e^- \rightarrow \gamma + Z^0$, where $Z^0 \rightarrow$ neutrinos Thus one will have $e^+e^- \rightarrow \gamma$ + missing neutral energy which is directly proportional to N_ν (the same process as discussed by Hearty *et al* but now at energies where a real Z^0 leads to the neutrinos) without contamination of the other decay channels

P Langacker[9] has taken some of these recent data and studied their implications for the yet undiscovered Higgs boson and top quark masses They do not constrain the former but do constrain $m_t < 210$ GeV (the top quark mass enters into radiative corrections that affect some weak-interaction processes) The weak-interaction angle (Weinberg angle θ_W) is known within errors as a function of m_Z and m_t The precise measure of m_Z thus gives a rather clear linear relation between $\sin^2\theta_W$ and m_t, and it is the errors on $\sin^2\theta_W$ that allow the range of m_t up to 210 GeV

A reduction of these errors, by a more precise measure of m_W/m_Z, will thus lead to a prediction for the mass of the top quark, the missing member of the three families of the standard model And if the SLC and LEP data are to be believed, three is the magic number ☐

PHASE TRANSITIONS

New ideas for the melting pot

Robert W Cahn

MELTING is distinct from other phase transitions in that it is not clear which of several mechanisms is responsible for initiating the process as temperature is raised On page 658 of this issue[1], Tallon joins a debate on what effect each of the possible precursors to melting may have on the extent to which crystals can be superheated

Following my discussion[2] three years ago of the first observations of crystalline superheating above the equilibrium melting point, and the intimate linkage of this phenomenon with the nature of the crystal surface, Maddox[3] described new, strong experimental evidence that melting is indeed initiated at a crystal surface Last year, Fecht and Johnson[4] (with myself acting as chorus[5]) proposed that, under circumstances that permitted superheating at all, there must be an upper limit, thermodynamically determined, to how far superheating can go The central idea was that an 'entropy catastrophe', beyond which the crystalline entropy would exceed that of the liquid phase, would determine this limit A few months later, Lele *et al*[6] proposed an alternative way of estimating the temperature of the upper entropy catastrophe (there is also a lower catastrophe, the Kauzmann temperature, that marks the limit of supercooling of a liquid/glass) It is this same question — the best way to estimate the upper limiting temperature for superheating — that Tallon also addresses

The crucial role of the surface in initiating melting has been underlined in several recent papers The important work by Pluis *et al* to which both Maddox[3] and I[2] drew attention has now been more fully described[7] as the melting point is approached, a layer of disordering gradually develops, its thickness grows very corresponding oligonucleotide probes, and screened brain cDNA libraries by hybridization Wada *et al*[2] and Gregor *et al*[3] have cloned what may well be the frog and chick versions of the same kainate-binding protein (KBP) This protein has a relative molecular mass of about 50,000 (about half that of the kainate receptor channel identified by Hollmann *et al*) and, again, the hydrophobicity plot typical of the ligand-gated-channel gene family The KBP exhibits about 25 per cent amino acid similarity to the last (carboxy) half of the kainate receptor channel cloned by Hollmann *et al* , but the first 350 amino acids of the kainate receptor channel are entirely absent from the KBP The KBP binds kainate, as it should, but does not function as a channel when expressed in oocytes

In summary, then, Hollmann *et al* have cloned at least one subunit of a functional glutamate receptor channel, the other two laboratories have cloned a related protein that binds glutamate (kainate) but whose function is at present unknown What could this KBP be? One possibility is that it is a subunit of a neuronal kainate receptor and that the channel will only function when other subunits are present Because the chick KBP is remarkably abundant in cerebellum and is only present on Bergmann glial cells there, other possibilities are likely The KBP could, for example, be a component of an uptake system or part of a glutamate receptor involved in a signalling that does not use an ion channel Glia have recently been shown to transmit signals to one another in response to glutamate[4], and this signalling system, which involves changes in intracellular calcium concentration, responds selectively to kainate Whatever the KBP is, it belongs to a previously undefined family, and because of its abundance in glia rather than neurons, it must play a role in some as yet unknown aspect of brain function

For neurobiologists, the cloning of a glutamate receptor channel is an exciting event To understand why, one must appreciate the role of glutamate receptor channels in brain function First, glutamate is the main excitatory neurotransmitter in the brain, and every neuron — as far as we know — has ion channels with receptors for glutamate The glutamate receptors are thought to form a complex family because they fall into a rich variety of pharmacological types, and, if past experience is any guide, the gene families will be even richer than the current pharmacology indicates Second, at least one pharmacologically defined type of glutamate receptor, the one named after the glutamate analogue NMDA (*N*-methyl-D-aspartate) that best activates it, is especially interesting The NMDA receptor is a site of action of the street drug, 'angel dust', is responsible for excitotoxic nerve cell death and has a key part in long-term potentiation, the phenomenon thought to underlie some forms of memory Furthermore NMDA receptors have been implicated in certain types of seizure and various neurodegenerative diseases, and in the reorganization of neuronal connections that depends on experience Heinemann's laboratory, from which the paper by Hollmann *et al* comes, has already started finding other family members related to their kainate receptor channel, and it is expected that an entirely new family of receptors, one that may include the NMDA receptor, will be identified through homology screening

Finally, an interesting sociological note Although the three groups that came first in the race to clone a glutamate receptor worked independently (and competitively), the research of two of them was carried out in different laboratories at the Salk Institute, and one of the co-authors in the third group was in yet another laboratory at the Salk Something about southern California must be good for research on excitatory amino acids ☐

BIOGEOCHEMISTRY

Effects of increased ultraviolet

T E Graedel

THE discovery of the Antarctic ozone hole has sparked tremendous discussion about the implications of increased ultraviolet radiation on geochemical and biochemical processes Because many of the atmospheric and marine chemical cycles strongly interact with those of the biota, changes in any of the systems imply changes in all These interlocking concerns formed the basis for a recent workshop* which brought together atmospheric chemists and physicists, marine and freshwater chemists, biochemists and biologists

The effects of changing ultraviolet fluxes can be studied by examining each term of what one might call the photochemical impact equation For a specific molecule i, the impact I_i can be written as

$$I_i = \int_{\lambda_{min}}^{\lambda_{max}} J(\lambda)\, \sigma_i(\lambda)\, \phi_i(\lambda) \mathrm{d}\lambda$$

in which $J(\lambda)$ is the incident flux, $\sigma_i(\lambda)$ is the absorption cross section and $\phi_i(\lambda)$ is the quantum efficiency (that is, the fraction of absorbed photons that cause the process under study, as opposed to having their energy dissipated in some other way) The integration limits are the atmospheric cut-off at about 290 nm at the short wavelength end, and the longest wavelength capable of producing an effect (generally in the range 350–400 nm) at the upper end

In the case of absorption by agglomerated particles — poorly characterized dissolved species or organisms, for which molecule-by-molecule approaches are inappropriate — the absorption cross-section and quantum yield terms are replaced by $A_i(\lambda)$ This 'action spectrum' is an experimentally determined measure of the effects of the interaction of light at a particular wavelength with a specific constituent A quantitative assessment of the effects of changing ozone concentrations requires a relatively complete understanding of each term in these equations, speakers at the workshop presented results related to each term

Changes in atmospheric ozone are now being monitored widely It does not follow, however, that even $J(\lambda)$, the present flux of solar radiation to the surface, is known accurately, because clouds play such a large role in the radiation balance The distribution and physical properties of clouds are not well characterized, particularly over the oceans and

---

**Effects of Solar Ultraviolet Radiation on Biogeochemical Dynamics in Aquatic Environments* Woods Hole, Massachusetts 23–25 October, 1989 the poles Calculations by S Madronich (National Center for Atmospheric Research, Boulder) predict that for mid- and low-latitudes, fluxes of biologically active UVB (290–320 nm) at the surface will change by −5 to +10 per cent by the year 2060, depending both on the model and the assumed course of ozone depletion For southern polar regions, large increases in springtime ultraviolet are expected (as much as a factor of ten in the year 2060) But because the average UVB irradiance is much higher at equatorial latitudes than at the poles, a percentage increase in UVB irradiance in the tropics corresponds to many more additional photons than the same increase at high latitudes

Increases in solar ultraviolet radiation seem certain to produce substantial changes in the composition of the atmosphere as a consequence of the absorption of the radiation by gaseous molecules Calculations by A M Thompson (NASA/Goddard Space Flight Center) indicate that the oxidizing power of the lower atmosphere will be much increased and that the atmospheric content of many trace gases scavenged by oxidizers will decrease Cloud effects pose large uncertainties, however, because soluble gas-phase species can interact with clouds (and aid in their formation) in ways not well understood, and because most atmospheric chemical models have yet to treat cloud effects

P Crutzen (Max-Planck-Institute for Chemistry) reported recent calculations in which cloud chemistry was added to a global two-dimensional model Although clouds occupy only about 15 per cent of the volume of the lower troposphere and liquid water occupies only 10^{-7} to 10^{-6} of a cloud's volume, the inclusion of clouds in the model greatly decreased the calculated concentrations of ozone, hydroxyl radical and nitrogen oxides, thereby affecting the budgets of many other trace gases (P Crutzen and J Lelieveld *Nature*, in the press)

Within condensed phases, the results of increased ultraviolet are also likely to be dramatic A few years ago, there was little evidence for the existence of reactive chemical transients in environmental waters Recently, however, several studies using carefully designed trapping-agent molecules have established the presence of such species as excited states, singlet molecular oxygen, solvated electrons, hydroxyl radicals, superoxide radicals, carbon-centred radicals and hydrogen peroxide All are generated by solar ultraviolet radiation Hydrogen peroxide is the longest lived of these transients and its widespread occurrence in the upper ocean and freshwaters provides an important marker of the influence of solar ultraviolet radiation in aquatic environments

The biological effects, on both plants and animals, of increased ultraviolet radiation can be assessed by species only if each $A_\lambda(\lambda)$, the appropriate species action spectrum, has been determined Useable action spectra are, however, rare T Coohill (Western Kentucky University) highlighted some of the problems uncertainty in the spectral purity of the incident radiation, difficult dosimetry determinations, the extent of biological repair before assay, the physical state of the target molecules, and response *in vivo* versus response *in vitro* Hence, assessments of the effects of changing ultraviolet radiation are, at present, much more likely to be qualitative than quantitative

In one of the workshop's more provocative presentations, F M M Morel (Massachusetts Institute of Technology) argued that one could logically defend any of the following positions Increased ultraviolet radiation will promote a dramatic increase in new primary biotic productivity, practically destroy biotic productivity, or have no discernible effect on biotic productivity His claim can be made because the quantitative information to determine the dominant effects is generally unavailable and because different factors seem likely to dominate at different places, times and seasons

Morel's first position was supported by several participants who pointed out that the bioproductivity of the oceans often seems to be limited by the availability of trace nutrients such as iron, copper and manganese Photochemical reactions involving bound forms of these elements increase their availability Hence, regions of the oceans that are now nutrient-limited may benefit from increased ultraviolet radiation

The converse position — that the increased damage to DNA will overwhelm any benefits in nutrient supply — was supported by several reports that UVB radiation markedly reduces growth in some species of marine phytoplankton The biological impact is related to the number and efficiency of DNA repair systems in organisms Field studies from Palmer Station, Antarctica (D Karentz, University of California, San Francisco) demonstrate that there are enormous interspecies differences in sensitivity to ultraviolet

Could increased ultraviolet fluxes have only little effect on biotic productivity? T Mill (SRI International) argued that concentrations of marine and freshwater reactive chemical transients are too low and their lifetimes too short to have major adverse effects on the biota It is also worth considering that marine phytoplankton already cope with reactive photoproducts and trace-element depletion ☐

DAEDALUS

Air of longevity

ONE of the appealing hazards of air travel is the ease with which you can get drunk The reduced pressure and oxygen content of the cabin slows the metabolic elimination of alcohol, giving two drinks almost the effect of three Daedalus therefore began to design a low-pressure pub Drinkers would have to enter by an air-lock, but could then get drunk more cheaply, and stay that way longer Conversely, increased pressure should speed up alcohol metabolism A high-pressure bedroom, for example, might enable the alcoholic to burn off his entire hangover overnight, and greet the morning after with a clear head

Daedalus is now extending this whole principle He points out that if fed on restricted diets, nearly all animals mature more slowly and live longer than usual Every creature studied seems to step through its whole 'life programme', from growth and sexual maturity to senescence and death, by the ticking of its metabolic clock Animals raised in low pressures should therefore have longer, slower biological careers. If the principle works with man as well, then by spending your whole life in a cruising aircraft you might live to be a hundred Or perhaps it would only seem like that

Low pressure may even space out the minor milestones of life The irregular menstrual cycle of many airline stewardesses has been attributed to their chaotic shuttling between time zones Daedalus suspects instead that they 'age' more slowly in the air, and get out of step with ground-level time

So DREADCO's physiologists are setting up a variable-metabolism unit To avoid the problems of pressurized construction, Daedalus contemplated slowing the oxygen metabolism of the inmates by introducing a little carbon monoxide into the air of the building But wiser counsels prevailed, and instead the oxygen concentration of its air will be varied directly Daedalus expects that his under-oxygenated volunteers will lose appetite and need only two meals a day To study ageing itself, he is appealing for middle-aged identical twins, one to live in the low-oxygen laboratory and one outside while microscopic examination compares the rate at which grey hairs appear on their scalps

The effects of oxygen-enriched air should also be interesting Metabolism may speed up sharply, so that obese volunteers are swiftly 'burnt down' to normal weight Animals may grow faster an oxygenated poultry house, for example, might hurry chickens to earlier maturity It would be hard to extend such atmospheric modifications to free-range life, whether in chickens or man, though an oxygen boost on the air conditioning might be welcome in many crisis-prone offices David Jones

Pneumologists breathe easy

SIR—I have read with interest the article "Model Lung Breathes True"[1] and the quoted paper by two physicists, Bonsignori and Salvini, *Il Nuovo Cimento*[2], which is said to "contain an intriguing calculation of gas transport in the human lung of a kind that would normally have been found in a physiological journal". In fact, the results of similar calculations belong to standard physiological textbooks[3]. In my opinion, the paper of Bonsignori and Salvini is only relevant to the respiratory physiology of the early 1970s.

Whatever the model (in physiology as in physics), comparison with experimental observations is the crucial test. What Maddox has written[1], that "the outcome of the calculations is much what physiologists would expect", is not true. The authors simulated a simple experiment, called single breath nitrogen washout, consisting of an inspiration of oxygen followed by an exhalation. Most of the expired-N_2 concentration profile, the so-called alveolar plateau, is not flat, as would be expected if the lung is a perfect mixing chamber. (The slope of the alveolar plateau is one of the standard indices in pneumology and is explained to medical students in elementary textbooks.)

The model of Bonsignori and Salvini simulates a flat alveolar plateau and the authors say that "in experiments, the single breath washout curves have rather flat alveolar plateaus, indicating uniform mixing of the alveolar and inspired gases"[2]. It is well known, since the experiments of Krogh and Lindhard[4] at the beginning of the century, that this is not the case. In other words, the lung model of Bonsignori and Salvini does not breath true.

Maddox also quotes Bonsignori and Salvini as claiming to have improved on some of the approximations to which previous calculations have been subject. These improvements consist of 1, using a better representation of the airway cross-section, 2, using a Taylor–Aris effective diffusion, and 3, discussing more appropriate boundary conditions. In a review on the subject[5], several references (probably not known by Bonsignori and Salvini) are given where all these points have been studied. None of these have significantly improved agreement between the model simulations and the experimental observations.

As Maddox says, the physiological data are striking, the total cross-section of airways increasing from a few square centimetres in the trachea to more than a square metre at the last generations of the bronchial tree. A major consequence of the lung geometry is that when we inspire at constant flow, the concentration profile of the inspired gases remains quasi-stationary, the convection flow of inspired gases towards the lung periphery being balanced by the diffusion flow of the residual (or alveolar) gases in the opposite direction[5]. This is the so-called diffusion front, equivalent to the stationary diffusion front in combustion science, when the combustion takes place in a tube with the appropriate convection velocity of gases.

A major development of models of gas mixing in the lung (not quoted by Bonsignori and Salvini) was the realization[5] in the 1970s that one of the most fragile assumptions in previous work consists of using the symmetrical Weibel model of the lung[6], which dates back to 1963. Not surprisingly, the first detailed asymmetrical model of the periphery of the human lung was recently published by Weibel's group[7]. Unexpected results appeared when a diffusion equation was written in an asymmetrical structure of ducts as a consequence of Fick's law of diffusion and matter balance in a branching tube: the flow of any gas in such a structure generates an inhomogeneous concentration distribution, even though the structure moves isotropically and homogeneously. This occurs in zones of the model that are subtended by branch points where the Péclet number (giving the relative contribution of convective to diffusive transport) is approximately unity. In the human lung during normal breathing, this corresponds to branch points subtending zones of the lung a few millimetres apart.

Simulated single-breath washout using these new models gives much better agreement with experimental observations than previous models[5]. This finding is of interest in that the single-breath washout, particularly when performed with tracer gases of different diffusivities such as He and SF_6, gives information on the structure of the very peripheral zones of the lung which are not accessible to traditional tests in pneumology nor even to modern imaging techniques such as positron emission tomography. To my knowledge, the description of gas transport in an asymmetrical lung model has no counterpart in physics or engineering, although it may have applications in the study of gas transport in porous media, or O_2 and CO_2 transport in some insect-built galleries, where the Péclet number may approach unity. It may also apply to the study of O_2 transport between capillaries and cells.

Physiology (which, in a way, is the physics of living beings) and physics were closely associated until the last century, and several discoveries in both fields were made by the same scientist: Boyle, Torricelli, Pascal, Hooke, Lavoisier, Laplace and Lagrange have contributed to the early development of respiratory physiology, and both Poiseuille and Fick were physicians. The bridge is much narrower today and the paper by Bonsignori and Salvini in *Il Nuovo Cimento* has the merit, as Maddox says, of establishing a new link. It also points out the necessity for the physicists who approach physiology to learn at least its elementary basis, if they want to avoid the trap of rediscovering the wheel. Bonsignori and Salvini promise a new paper where they will pay particular attention to the question of the boundary conditions in the model. If they do not in the meantime read the published literature, respiratory physiologists need not hold their breath awaiting future issues of *Il Nuovo Cimento*.

PCR origins

SIR—We noted with interest the short note, entitled "DNA amplification" (*Nature* **341**, 570, 1989) which suggests that scientists who use PCR "dust off" the *Journal of Molecular Biology* from 1971, and read the paper by "H. Gobind Khorana and colleagues". Although the title and text of your note might suggest otherwise, the "lines of thought" and reference to experiments "in progress" in this 1971 article did not present a method that could be used to perform *in vitro* DNA amplification. The scientific community had to wait for such a method until, 14 years later, Kary Mullis invented the polymerase chain reaction (PCR).

Your readers might be interested to know that the articles written by Kary Mullis, Henry Erlich and their co-workers at Cetus describing the PCR method and its application have been cited in well over 1,000 publications since 1985. None of these publications cite the 1971 article to which you draw attention. Cetus is confident that Kary Mullis will continue to receive the recognition he deserves.

Similarity in membrane proteins

SIR—Adams and Pollard[1] recently discovered that the nonfilamentous myosins IA and IB of *Acanthamoeba* can bind to membranes, a finding with important implications concerning the role of these proteins in cell motility We would like to draw attention to a 50-amino-acid domain in the sequence of the myosin-IB isozyme[2] that is shared with a diverse family of cytoplasmic proteins, many of which are associated with the plasma membrane (see figure) This domain, called SH3 or the A-box, was first described as a region of sequence similarity between the non-receptor protein-tyrosine kinases, the 148K phospholipase C (PLC), and the v-*crk* oncogene of the avian sarcoma virus CT10 (refs 3 and 4) It was subsequently found in the α-chain of the non-erythroid spectrin homologue, fodrin[5]

Upper-case letters denote identity with the myosin-IB sequence The amino-acid number of the first residue of each sequence is given in parentheses ϕ signifies hydrophobic residues The PIR database was searched using the programs Prosearch (J Collins and A Coulson, University of Edinburgh) on an AMT DAP, and AMPS (G Barton and M J E S) on a VAX 8700, the Genepro program (Riverside Scientific, Seattle) was used to search the EMBL database

Our database searches have also revealed SH3 domains in cdc25 and fus1, two proteins of another single-celled eukaryote, *Saccharomyces cerevisiae* The fus1 protein on the cell membrane is essential for cell fusion during mating[6,7], cdc25 is a regulator of the membrane associated adenylyl cyclase The SH3 motif is, therefore, shared by membrane-associated proteins of both single-celled and higher eukaryotes This conservation indicates a basic function common to all eukaryotes but this function is still a mystery Although SH3 is found in many proteins at the cell periphery, it is not universal, it is absent from erythroid spectrin for instance

Adams and Pollard[1] mapped the membrane-binding region of myosin-IA to a 100K N-terminal chymotryptic fragment, but the binding region of myosin-IB has not yet been localized Intriguingly, the SH3 domain of the IB protein is close to the protein's ATP-independent actin-binding site[8] It will be interesting to see whether the SH3 domains of myosin-IB and other proteins play a role in binding either directly to membranes or to the submembrane cytoskeleton

What are males good for?

SIR—Successful rearing of young in most birds requires the care of two adults Such parental pairs are almost always a male and a female, but the discovery of female/female pairings in one tern, one goose and several gull species, discussed by Jared Diamond[1], demonstrates that other parental pairing combinations are possible Female/female pairs are, nevertheless, rare even in these few species[2–6] Determining the reasons why they are so uncommon may help to formulate answers for the old question 'What are males good for?'

The most obvious benefit to females of pairing with a male — access to a source of sperm — is probably not of primary importance, as females paired together still copulate with unmated and mated males[7] Female/female pairs, therefore, produce fertile eggs, although their fertility rates may be less than those of male/female pairs[4–6]

Perhaps a more important advantage provided by males is that of a territory Female birds are generally smaller than males, and may, therefore, be at a disadvantage when competing against a male for a territory In all the colonies where I have found female/female pairs or the unusually large (5–7 egg) clutches that result from them[2,8] (eight ring-billed gull colonies, four California gull colonies and a Caspian tern colony), space for more nesting pairs was available on the nesting islands In western gulls, female/female pairs were found in one colony where there was little competition for breeding space, but no such pairs were found in another colony where breeding space was limited[9]

Probably the most important advantage a female derives from pairing with a male is the opportunity to raise only her own young (nest parasitism aside) By contrast, each female in a homosexual pair will contribute, on average, only half the young An unrelated pair of females must, therefore, produce twice the offspring of a heterosexual pair before the reproductive output of each homosexually paired female equals that of a

of the aborted zygotes This must also be true in species where it has been shown (by experimentally destroying competing embryos) that aborting embryos are not intrinsically inviable[14] Such evidence also rules out maternal choice among embryos, or sibling competition, if based on the genotypes of the embryos In many species, however, nonrandom abortion is difficult to demonstrate, and most species have some random abortion We cannot therefore exclude a contribution of mutational load to low female fertility

It is certainly worth considering the additional possible causes mentioned by Bawa *et al* for the patterns of abortion and low ovule fertility seen in some plants (parent–offspring conflict, providing excess ovules so that maternal choice can occur, and pollen competition) These hypotheses are difficult to test, and are at present rather controversial, and I did not have space to mention them in my brief discussion of the question The first is closely related to the high cost of fruit and seed maturation, discussed in my News and Views in terms of theories of resource allocation which show that this cost can lead to the evolution of low female fertility, even though potentially viable progeny are lost Pollen competition does not seem a likely explanation for species with regularly low seed to ovule ratios, because some pollen sources should yield seeds from every ovule, which does not appear to be possible in such plants[15]

DEBORAH CHARLESWORTH
Department of Ecology and Evolution,
University of Chicago,
Chicago, Illinois 60637, USA

WIENS *ET AL* REPLY—Our letter to *Nature*[2] reported extensive (97 5 per cent) genetically mediated developmental failure of ovules and consequent loss of reproductive capacity in *Dedeckera eurekensis* (Polygonaceae), a rare, palaeoendemic, monotypic genus from the Mojave desert of California

Bawa *et al* question both the uniqueness and interpretation of our results They indicate that mimosoid legumes have exceptionally low fruit/flower ratios (per cent fruit set), but relatively high seed/ovule ratios (per cent seed set) giving these plants overall seed set similar to *Dedeckera* (2–3 per cent) We have confirmed these results in African *Acacia* and North American *Prosopis* Apocynaceae and Asclepiadaceae behave similarly, as do many woody groups, and plants reproducing vegetatively These reproductive systems, however, are not comparable to that of *Dedeckera*

In mimosoid legumes low fruit set is genetically programmed by the maternal genome The great majority of ovules are probably unfertilized, or if fertilized, probably abort before the activation of the zygotic genome at differentiation, or their maturation is physiologically inhibited by earlier developing fruits Such ovules never enter the potential seed pool

Maternal fitness, however, is determined by the absolute number of fully viable seeds produced In spite of the low fruit set per inflorescence, a mimosoid may produce hundreds or possibly thousands of inflorescences with one to several fruits and thousands of seeds

In *Dedeckera* more than 95 per cent of the ovules are fertilized (flowers are uniovulate) and develop to various stages The few filled seeds that mature occur randomly in the inflorescence, any ovule can potentially enter the seed pool The 97 5 per cent abortion rate among *Dedeckera* ovules, however, represents only a portion of the reproductive loss Large, vigorous plants of *Dedeckera* may produce about 64,500 flowers (and ovules) Of the 2 5 per cent of filled seeds only 3 5 per cent germinate spontaneously, and only 11 per cent are without post-developmental abnormalities Most *Dedeckera* plants probably produce less than 50 fully viable seeds annually Some plants are apparently totally sterile Seed inviability of this magnitude seems unprecedented among any evolutionary successful species

Severely reduced seed sets (inbreeding depression) are often encountered when typically outcrossing plants are selfed Such results are of little interest The similarly low seed sets obtained in *Dedeckera* from both outcrossing and inbreeding are precisely what make it so unusual The genetic load in *Dedeckera* is perhaps so high that rare, recombinant gametes produced upon selfing may have as great a probability of producing a viable embryo/endosperm as outcrossed progeny A number of phylogenetically and geographically rare plants (monotypic families) seem to have reproductive capacities similar to *Dedeckera* These endangered plants may also exhibit unusual genetic phenomena not heretofore encountered They require urgent study

The failure of ovular development in general is attributable to several causes Nonrandom abortion (maternally controlled) is exceedingly common and likely under fixed genetic control of the maternal genome[16] Random ovule abortion is primarily attributable to genetic load and developmental selection[16,17]

Our previous letter on *Dedeckera* is essentially concerned with reduction of fitness, and presents a difficult evolutionary conundrum If the loss of fecundity resulted in continued population decline, why would selection not reverse the trend? We proposed a heterosis (balanced-load) model that allowed for the survival of unique, highly heterozygous genotypes in an environment stressed by increasing aridity Such genotypes should suffer drastically reduced fecundity from genetic load Selection, however, must firs ensure individual survivorship, thei fecundity This could ultimately lead t extinction

How can such a situation be reconcile with sibling rivalry/parent–offspring conflic hypotheses? How can they explain th high loss of seed viability, germinability and the presence of extensive postger mination developmental abnormalities all of which follow the release of seed from the maternal plant? Likewise, ho can they account for embryo death similar to those known to be controlled b developmentally lethal genes[18]

These highly anthropomorphic, socio biological hypotheses are best not applie to plants We suggest they cannot b tested critically, and have no mechanis to explain their operation The causal mechanistic genetic based hypotheses although not without difficulties, ar founded on established phenomena an Occam's razor dictates their acceptance

Since publication of our letter, we hav carried out a more extensive crossing pro gramme in which *Dedeckera* showed tha of 157 self-pollinated flowers (uniovulate one filled seed was obtained, and of 19 cross-pollinated flowers, 23 filled seed (12 0 per cent) were obtained (N = plants)

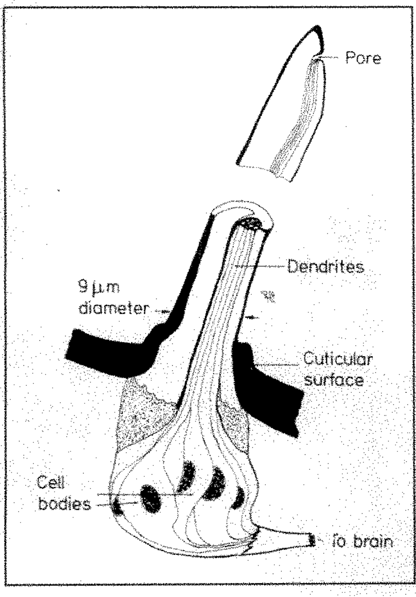
Chemistry of Plant Protection

Managing Editors: G. Haug and H. Hoffmann

Series Editors: W. S. Bowers, W. Ebing, D. Martin, R. Wegler, I. Yamamoto

This series continues the handbook "Chemie der Pflanzenschutz- u. Schädlingsbekämpfungsmittel", edited by R. Wegler.

Forthcoming volumes:



▼

Volume 1

Sterol Biosynthesis Inhibitors and Anti-Feeding Compounds

1986. IX, 151 pp. 30 figs. 12 tabs.
Hardcover DM 106,– ISBN 3-540-13487-5

Contents: *T. Kato:* Sterol Biosynthesis in Fungi, a Target for Broad Spectrum Fungicides. – *W. Krämer:* Chemistry of Sterol-Biosynthesis Inhibiting Fungicides. – *K.-H. Kuck, H. Scheinpflug:* Biology of Sterol-Biosynthesis Inhibiting Fungicides. – *D. M. Norris:* Anti-Feeding Compounds.

Volume 2

Degradation of Pesticides, Desiccation and Defoliation, ACh-Receptors as Targets

1989. X, 246 pp. 42 figs. 47 tabs.
Hardcover DM 148,– ISBN 3-540-13488-3

Contents: *P. R. Wallnöfer, G. Engelhardt:* Microbial Degradation of Pesticides. – *U. Schoknecht, D. Otto:* Enzymes Involved in the Metabolism of Organophosphorus, Carbamate and Pyrethroid Insecticides. – *R. Richter, D. Otto, H.-J. Mengs:* Insecticide Compounds, Acting on the Acetylcholine Receptor of the Insect Nervous System. – *H. Bergmann, D. Martin:* Chemical Manipulation of Desiccation and Defoliation and Essential Aspects for the Application and Development of New Chemical Compounds in the Future.

Volume 3

Pyrethroid Residues, Immunoassays for Low Molecular Weight Compounds

1989. Approx. 150 pp. 10 figs. 97 tabs.
Hardcover DM 148,– ISBN 3-540-51312-4

Contents: *W. Blaß:* Residues of Pyrethroid Insecticides and Their Analytical Determination. – *E. W. Weiler:* Immunoassay for the Quantitation of Low Molecular Weight Compounds in Plants.

Volume 4

K. Naumann, Leverkusen

Synthetic Pyrethroid Insecticides, Structures and Properties

1990. Approx. 240 pp. 35 figs. 114 tabs.
Hardcover in preparation.
ISBN 3-540-51313-2

This volume provides an in-depth overview of structures, properties, stereochemistry, conformation, biological data and modes of action, toxicity, and application of synthetic pyrethroids. A chapter on commercial and market aspects concludes the book.

Contents: Biologically Active Pyrethroids.– Biological Action of Pyrethroids Against Living Organisms.– Mode of Biological Action of Pyrethroids.– Pyrethroids as Commercial Insecticides.

Prices are subject to change without notice.

Volume 5

K. Naumann, Leverkusen

Synthetic Pyrethroid Insecticides, Chemistry and Patents

1990. Approx. 350 pp. 5 figs. Hardcover in preparation. ISBN 3-540-51314-0

This volume presents a detailed survey of the synthesis of pyrethroids and of almost every of the respective patent applications for synthetic pyrethroid active ingredients.

Contents: Synthesis of Pyrethroid Acids. – Synthesis of Important Pyrethroid Alcohols. – Formation of the Pyrethroid-ester-linkage. – Non-Ester Pyrethroids. – Analysis of International Pyrethroid Patent Activity.

Volumes 4 and 5 of the series provide the first complete and in-depth overview of synthetic pyrethroid insecticides and will be of utmost value to industrial chemists, biologists, molecular pharmacologists and patent professionals involved in pyrethroid chemistry.

Volume 6

Controlled Release, Biochemical Effects of Pesticides, Inhibition of Plant Pathogenic Fungi

1989. Approx. 290 pp. 95 figs. 26 tabs.
Hardcover DM 158,– ISBN 3-540-51316-7

Contents: *M. Bahadir, G. E. Pfister:* Controlled Release Formulations of Pesticides. – *M. Eto:* Biochemical Mechanisms of Insecticidal Activities. – *P. Böger, G. Sandmann:* Modern Herbicides Affecting Typical Plant Processes. – *H. Buchenauer:* Physiological Reactions in the Inhibition of Plant Pathogenic Fungi. – *M. A. Q. Khan:* Biochemical Effects of Pesticides on Mammals.

YOUR WEEKLY BIOMEDICAL UPDATE

Until now, researchers have had to spend many hours each week scanning numerous journals and current awareness publications to keep up-to-date with recent developments in their respective fields. Now, with Medical Science Weekly, there is a quick and easy way to keep up-to-date using your own PC.

Medical Science Weekly is best described as a computerised current awareness journal. Each week, you receive a floppy disk with details of the complete contents of over 1000 of the most important biomedical research journals.*

Medical Science Weekly is easy to use. You place the disk in your drive, and, by typing one or two keywords, retrieve all the current articles published in your research field. You can also search for a particular author or reproduce the contents lists of your favourite journals.

Medical Science Weekly is fast. All items from a journal issue are available for distribution within 5 days of receipt at our office.

Receive your weekly update the easy way – at a surprisingly low price! Return the coupon below and we will send you more information and a complete sample system, or call on + 31-6-022-1766 (Europe) 800-HLP-EMED, or (212)-633-3971 (USA and Canada).

Anatomy of a conflict

Shepard Krech III

Archaeological Perspectives on the Battle of the Little Bighorn. By Douglas D. Scott, Richard A. Fox, Jr, Melissa A. Connor and Dick Harmon. *University of Oklahama Press: 1989. Pp. 309. Hbk $24.95.*

WHAT more could possibly be said about the Battle of the Little Bighorn that has not been? An event that electrified the country the instant it happened, it continues to excite the imagination. Biographies have been written on the principals involved on both sides — George Armstrong Custer, Crazy Horse and others — as have numerous detailed accounts, from both Indian and white perspectives, of the battle itself and the historical circumstances leading up to and following this epic confrontation, on 25 June 1876, between the US Seventh Cavalry and the Sioux and Cheyenne Indians.

Illuminating the past — H. Charles McBarron's painting of Custer's last stand.

Peter Newark's Western Americana

There are no lingering significant controversies in the interpretation of this historical record. But because there are different perspectives, and because the production and re-production of history is invariably a cultural, presentist exercise, conflicts persist over the interpretation of details in the voluminous historical archive, which probably will occupy historians well into the future. Nevertheless, when one reads on a book jacket that assembled therein is "the most compelling and convincing evidence thus far of what happened on that day in southeast Montana 113 years ago", one can be forgiven for suspecting a publisher's marketing department of hyperbole.

Indeed, the aims of the authors of this book are far more modest, even though at times, it seems, they also are caught up in Little Bighorn hype when they are not actively proselytizing for the revisionist potential of historical archaeology. Grasping the opportunity presented by a grass fire that removed vegetation on the Custer Battlefield National Monument, the authors (of the four, one is a military archaeologist, another an expert on firearms) undertook a comprehensive programme in historical archaeology to determine where 28 soldiers killed in a cul de sac were interred; whether marble battlefield markers actually were placed over human remains; what the bones of troops reveal about diet, trauma and death; how combatants moved about the battleground; and what firearms were used.

The results of archaeological investigations — metal-detector surveys, shovel and backhoe excavations — are mixed. The authors failed to discover the remains of the last 28 soldiers, but they think they now know, by the use of geomorphology and archaeology techniques, where the troopers cannot be and where they are likely to be found. As for the markers, some are improperly placed, not surprisingly because the dead were 'buried' three or four times: the day after the débâcle, the bodies were covered; in 1877 and 1879, exposed remains were reinterred; and in 1881, disinterment was followed by reburial in a mass grave. Nine years later, marble markers were placed on the battlefield, and the following year a map was prepared. Little wonder there are discrepancies. The bones show ample signs of trauma after death, to which all historians concur and about which, for cultural context, Indian sources are most revealing.

The distributions of cartridge-case, bullet and other artefactual materials on the battleground make interesting figures, despite predictable (and wooden) assessments — "the number of bullets impacted in the defence perimeter strongly suggests that the incoming fire must have been heavy" (p. 140). Although plotting distributions leads to a "further clarification" (p. 138) of the positions of the combatants or "correlates well with the historically known combatant positions" (p. 134), it unfortunately adds little to the known historical record.

The most interesting results concern the identification and analysis, on the basis of cartridge cases and bullets, of types and quantities of firearms used by Indians and whites. More than 40 types of guns were used in the battle, and the distribution of types — even of individual weapons — can be derived from signatures that guns leave on bullets and cartridge cases. Even here, however, the archaeological record in part corroborates extant archival materials: a list of guns surrendered by the Sioux and Cheyenne in 1877.

Despite their evident enthusiasm for historical archaeology, the authors wisely state that they do not believe it represents "the last work" (p. 11) in the study of the Little Bighorn. Indeed, apart from often being able to corroborate the known historical record, the conclusions that one can draw from this work are limited Similarly, where the historical record is in dispute, the illuminations provided by historical archaeology are few, with one exception: bullet and cartridge-case distributions support Indian, not white, accounts of the battle. ☐

Keeping them up in the air

Thomas A. McMahon

Bird Flight Performance: A Practical Calculation Manual. By C. J. Pennycuick. *Clarendon: 1989. Pp.153. £25, $49.95.*

On the wing — recently published, *The Birds of South America* by R. S. Ridgely and G. Tudor, is the first volume in an intended series of four. The initial volume is subtitled *The Oscine Passerines* and encompasses more than 700 species of songbird. Thirty-one colour plates, drawn by Guy Tudor, illustrate the text of Robert Ridgley. This work is seen as a valuable contribution to the recording and appreciation of the birds of South America — especially appropriate at a time when rapid development is devastating millions of acres of tropical habitat in South America. The subsequent volumes of *The Birds of South America* will be: The Suboscine Passerines; The Nonpasserines (Landbirds) and The Nonpasserines (Waterbirds). This illustration is taken from the cover of the first volume, published by Oxford University Press, price £45.

THE subtitle says this book is a "practical calculation manual". Right away, the prospective reader wonders what that could be. Manuals are generally not much fun for off-duty reading. There are many people who might like to read an informative book about bird flight, but few who need to make calculations. The prospective reader wonders if this is a book or a computer manual, and if it's a manual, shouldn't it be someone else's job to read it?

The first chapter doesn't make the question go away. In the very first paragraph, the author launches into a discourse about how millilitres of oxygen and grams of fat are not units of energy. He reveals here, as in other places in the book, that he is on a mission to set some of his colleagues straight about the right way of doing certain things. On p.11, for example, he draws the right and wrong methods of tracing a wing to find its area. On p.8 he says that some collections of data in the literature have to be treated with caution "because ornithologists have proved surprisingly creative in inventing wrong ways to make even the simplest measurements".

Not until the reader is well into the book does it dawn, like a bright light switching on, that this volume — manual or not — represents a beautiful and original achievement. From then on, it doesn't matter whether it is a book, a manual or a computer program (actually, it is all three). What matters is that Pennycuick has invented something here; a way of exploring a complex biological subject through first-hand revelations using a calculation model.

It is a very successful invention. Books are good tools for self-education, but Pennycuick obviously believes there are better ways to learn. The best way is not to be told the answer but to be given the opportunity to discover it for oneself. Pennycuick's invention is not at all like computer-aided instruction, where the program asks the user a question and then scolds and corrects when it thinks the answer is wrong. Using the programs provided here, the user is responsible for formulating a scientific question. An example (p.88) might be: why do birds of intermediate size use a mode of intermittently powered flight (bounding) in which the wings are folded against the body during the non-flapping phase? The user can work out answers to such questions by obtaining measurements, not on animals, but from a calculated simulation of what the animal would do in the presumed situation. Most of the book concerns explanations of how the programs arrive at their answers. Pennycuick provides brief discussions of the physical and biological principles behind the calculations, emphasizing throughout the importance of selecting and configuring the program for the task at hand and staying within the limitations inherent in the program's assumptions. He has made it straightforward to change the assumptions when necessary, as, for example, when the air density is lower because the bird is flying at altitude.

The book is full of fresh insights I have never seen published. I liked the very simple and clear discussion of Reynolds number on p.43, where the author points out that the ratio of inertial force to viscous force acting on the air in a little cube flowing around an obstruction grows larger if you scale the whole drawing up because the ratio of the cube's mass to its surface area increases. On p.50 I was told that a snow goose body in a wind tunnel has 15 per cent less drag when the feathers are coated by hair spray. In a living bird, the feathers can be controlled by pteromotor muscles, presumably giving some of the same effect. On p.62, there is a diagram of the concertina wake, in which the bird flexes and shortens its wings on the upstroke while flapping, so that no transverse vortices are shed, and consequently less energy is required than would be the case for flapping wings of fixed span.

A particularly nice use of the programs included with the book is discussed on p.107, where the author asks why small birds don't take advantage of the energy in the atmosphere and soar as large birds do. He shows how his programs can produce a telling calculation comparing a 5.5-kilogram crane to a 17.4-gram ovenbird, assuming both birds have 1 metre per second thermals to soar in. Whereas the crane requires only 15 per cent as much energy per kilometre to migrate using thermals as to flap along in still air, the little ovenbird uses 6 per cent *more* energy per kilometre riding the thermals. The reason the small bird comes out so badly is that its basal metabolism is a much larger fraction of the total energy requirement. Because the small bird spends almost three times as long using thermals as it would flying direct, the extra time results in an extra cost for basal metabolism that overwhelms the energy savings that would be available from gliding instead of flapping. ☐

Thomas A. McMahon is in the Division of Applied Sciences at Harvard University, Cambridge, Massachusetts 02138, USA.

presumed rules, and that accounts for evolution It is not clear how a primaeval bacterium can have the incipient structure of both a mammal and an angiosperm, but I assume that these laws of structure allow for — even require — a rigid, prescribed sequence of change It is also possible, as some of the authors suggest in this symposium volume, that one might have a mixture of natural selection and these laws of structural transformation, the latter dealing with the important changes in form It is argued, for instance by M Ito, that convergence in evolution is not explained by the standard idea of similar selection pressures producing similar structures, but that the reverse is true the primordial structure is the same and that is why different kinds of organisms produce the same shapes There is even the interesting suggestion by K Ikeda that these structural rules might be exerting their influence directly on the DNA of the genome in the form of super control elements

The problem of development receives considerable attention from a number of authors, especially Brian Goodwin He seeks these laws of structure and asks whether perhaps some of the reaction-diffusion models of development inspired by Alan Turing, or the mechanochemical model of Murry, Odell, Oster and others, might lead us into the structural laws The arguments for this and other more directly genetic influences on development are intelligent and sophisticated, but Goodwin has not made me a convert For me, the quest of the grail of developmental biology is not some hidden set of laws, but a simple unravelling of the web of mechanisms that control development I see the experimentalist who does developmental genetics as being on the right track, and there is much in current progress to encourage that view

There is another aspect to structure and evolution development that should be mentioned Many authors have recently pointed out that organisms can only build in one generation, or change over many, if they use the building blocks which are available to them They have called these 'constraints' and made much of the obvious point that neither evolution nor development can make wildly abrupt morphological shifts It is in these very constraints where structuralists see the hidden power that will explain all

To return to the volume, let me say that it is a mixed bag of essays Gerry Webster introduces the topic and many of the papers directly address the idea of structuralism, some clearly also embracing darwinism A few are wonderfully impenetrable, while others, such as the short paper of K Ikeda, are models of clarity

D'Arcy Thompson's *On Growth and Form* is often referred to in the book, and this adds yet another facet to the psychological problem For Thompson a satisfying explanation was a mathematical description I understand and respect this, but it does not satisfy me For the structuralist there is an unknown set of rules that govern form, but that does not satisfy me either, for I feel they may not exist and certainly it is unlikely that we will ever find out what they are I am quite happy with vulgar natural selection and developmental genetics ☐

John Tyler Bonner is in the Department of Biology, Princeton University, Princeton, New Jersey 08544, USA

New development

Tim Hunt

Genes and Embryos. Edited by D M Glover and B D Hames *IRL/OUP Press 1989 Pp 228 Hbk £27, $59, pbk £18, $38*

UNDERSTANDING how genes control embryonic development is one of the most important and exciting aims of biology Thomas Hunt Morgan and his colleagues at Columbia University understood this when they provided the basis of modern genetics, but they made only modest progress in discovering how genes actually shape the organism In the fruitfly *Drosophila melanogaster*, however, they chose the right organism to solve their problems, as Morgan's followers have since triumphantly demonstrated The many advances in cell and molecular biology of the past 20 years or so were required, however, to confirm and flesh out the *Theory of the Gene* (Yale University Press, 1926)

But let us not forget that creatures that 'don't have genetics' have also shed light on development amphibians led and arguably continue to lead the way in the study of induction (with nematodes coming up fast on the inside) Good progress (considering the formidable technical problems posed by development within a womb) has been made in describing and analysing mouse embryogenesis Surprisingly, many of the key genes that control development in flies are found in vertebrates too, where they probably work in not-too-dissimilar ways In fact, a tremendous amount is now known, and astonishing principles are emerging at an accelerating pace

Now is a good moment to tell the world about these new understandings People like me sense that these are stirring times but have trouble keeping their segments, parasegments, gap- and pair-rule genes in their correct conceptual slots Stripey flies, mammalian homoeobox genes and growth-factor receptor homologues in worms and flies are frequently reviewed in specialist journals, but it would be wonderful if someone could put it all together and tell, if not *the* story, at least a well illustrated outline of what the story i going to be This will take more than minireview in *Cell* or an article in *Trend in Genetics* Perhaps the nearest approac to this ideal is chapter 16, "Cellular Mechanisms of Development", in *Molecula Biology of the Cell* (eds B Alberts *et al* 2nd edn, Garland Press, 1989)

I had hoped that *Genes and Embryo* was the book I was looking for, but sadly i is not Perhaps its opening sentence give the game away "This book reviews th exciting discoveries made over recen years which contribute to our understanding of development at a molecular level It is the *molecular* that presents th problem, I think, for the authors are al excellent and their organisms apt

Almost half the book is allotted t *Drosophila*, Kathryn Anderson, Michae Levine and Katherine Harding giv commendably up-to-date accounts o developments in this fast-moving an tremendously impressive field But thei densely worded chapters are too sparsel illustrated for easy comprehension M favourite chapter is that by Kennet Kemphues on the nematode worm H achieves a nice balance of backgroun information, methodological explanation shows some striking pictures and provide food for thought Comparatively less i understood of frogs and mice, and it i understandable that the chapters by Tor Sargent and Ian Jackson are increasingl devoted to descriptions of particula genes that happen to have been studie and, particularly for the mouse, t purely methodological considerations Les attempt is made to give an integrated o comparative view of the principles o development of these more complicate organisms Perhaps it is still a bit to soon

The dream book of late twentieth-century embryology thus remains to be written It will need expert authors who meet to argue and refine their ideas and their presentation as well as a sympathetic editor and a gifted illustrator The result will be a fantastic story — one that I had never thought to hear in my lifetime ☐

Tim Hunt is in the Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge CB2 1QW, UK

In paperback

- Just published by Cold Spring Harbor Press is *Molecular Genetics of Early* Drosophila *and Mouse Development*, edited by Mario R Capecchi Part of the series Current Communications in Molecular Biology, the book reports the proceedings of the Banbury Center meeting held on 20–23 April 1989 Price is $24 00
- Also just published in the same series is *Polymerase Chain Reaction*, edited by Henry A Erlich, Richard Gibbs and Haig H Kazazian Jr Price is $22 00

New from Cambridge

Neutrino Astrophysics

JOHN N BAHCALL

Written by a distinguished astrophysicist, this advanced text presents a lively, thought provoking, and informative summary of neutrino astrophysics It combines results from various disciplines, providing a timely and unified discussion of the field It includes a detailed annotated bibliography and reference section

Techniques in Comparative Respiratory Physiology

Edited by **C R BRIDGES** and **P J BUTLER**

This book provides a practical and experimental guide to the techniques which are taking comparative respiratory physiology into new areas Many of the techniques used by respiratory physiologists working on animals have been adapted from medical research Conversely, there are a number of techniques developed by animal physiologists which find application in the fields of medical and veterinary science

Animal Re-introductions

The Arabian Oryx in Oman

MARK R STANLEY PRICE

In 1972 the last herd of wild Arabian oryx was destroyed, the oryx had inhabited the Arabian desert for millenia, until eventually eradicated by man Mark Stanley Price's book describes the reason for the Oryx's extinction from the wild and how the zoo-bred animals were introduced into the extreme and demanding habitat of central Oman's deserts

Charles Darwin in Australia

F W NICHOLAS and **J M NICHOLAS**

In 1836 the *Beagle* docked for two months in Australia During this time Charles Darwin travelled widely making extensive notes on the geology, flora and fauna of the continent Combining the Australian section of Darwin's diary with previously unpublished extracts from his notebooks, this attractively illustrated book is the definitive account of his visit

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously

Nature is an international journal covering all the sciences Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields Please write clearly and simply, avoiding unnecessary technical terminology *Nature's* staff will edit manuscripts to those ends if necessary Contributors should check their proofs carefully

Because of the competition for space, many of the papers submitted for publication cannot be accepted For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words

CATEGORIES OF PAPER

Review Articles survey recent developments in a field Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator Length is negotiable in advance but must not exceed six pages of *Nature*

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications

Articles may contain a few subheadings of two or three words The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows There should be fewer than 50 references

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature* The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study Letters should not have subheadings or more than 30 references

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research Some are commissioned, most are unsolicited They are normally between one and four pages of *Nature* in length

News and Views articles are intended to inform non-specialist readers about a recently published advance Suggestions should be made to the News and Views Editor Illustrations are welcome Proposals for meeting reports should be agreed in advance

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature* Priority is given to contributions of less than 500 words and five references Figures are welcome

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only Four copies are required, each accompanied by lettered artwork Four copies of half-tones should be included Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number Original artwork should be unlettered Ideally, no figure should be larger than 28 by 22 cm Figures with several parts are permitted only if the parts are closely related, either experimentally or logically Suggestions for cover illustrations, with captions, are welcome Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published

Colour Artwork. A charge of £500 a page is made for 4-colour figures Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible The figure should be described first, then, briefly, the method Reference to a method described elsewhere is preferable to a full description Methods should not be described in detail in the text

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate) Text should not be included in the reference list References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65) The first and last page numbers should be cited Reference to books should clearly indicate the publisher and the date and place of publication

Abbreviations, symbols, units and Greek letters should be identified the first time they are used Acronyms should be avoided as much as possible and, when used, defined Editors will shorten words if necessary In case of doubt, SI units should be used

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named

Acknowledgements should be brief Grant numbers and contribution numbers are not allowed

Submission *All manuscripts may be submitted to either London or Washington They should not be addressed to editors by name Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT)*

Chemical asymmetric synthesis

John M. Brown & Stephen G. Davies

Thalidomide comes in two forms a left-handed compound which is a powerful tranquilizer, and a right-handed version which can disrupt fetal development, causing severe handicap As a necessary consequence of synthetic methods available in the early 1960s the two forms were present in equal proportions in the manufactured drug, with catastrophic consequences The thalidomide story is perhaps the most painful reminder of the importance of stereochemistry—the spatial ordering of groups in a molecule can be as influential as the chemical nature of the groups themselves A principal problem in organic synthesis is, therefore, the development of methods for producing complex molecules with a stereochemically defined structure

OVER millions of years the complex architectures of enzymes (average relative molecular mass 50,000) have developed into efficient and specific templates for only one hand of organic reactant Since the first synthesis of an organic compound by a chemist in 1824, relatively small and simple reagents (average relative molecular mass <100) have been developed to achieve the synthetic transformations necessary for the construction of organic molecules Despite enormous advances in synthetic methods, which have made the construction of virtually any desired compound feasible, the problems of producing single-handed compounds seemed insurmountable and synthetic compounds were always produced as equal mixtures of left and right hands Recently, however, several breakthroughs in synthesis have occurred whereby more sophisticated, single-handed reagents or catalysts (relative molecular mass <800) have been invented which control the handedness of the product compounds with efficiencies rivalling those of enzymes

In structures of biological interest, such as natural products or synthetic enzyme inhibitors, there are one or more (often several) saturated carbon atoms with four different substituents attached and this tetrahedral arrangement can be either of the possible hands Figure 1 shows the hydration of but-1-ene in which the addition creates such a chiral centre and here, because no selectivity has been imposed, both enantiomers are formed A chemical reagent that is itself chiral may select in favour of one of these, producing a homochiral product If the reactant already possesses a chiral centre then the products, diastereomers, are no longer simply related as object and mirror image and they have different chemical and physical properties This is illustrated in Fig 1*a* by the hydration of homochiral 3-hydroxybut-1-ene The art of asymmetric synthesis is in controlling reactions so that one enantiomer or diastereomer is produced predominantly or exclusively[1-3]

Classical methods for the production of homochiral compounds generally involve some form of resolution experiment, such as Pasteur's manual separation of enantiomorphic crystals or the fractional crystallization of diastereomers[4] If the asymmetric centre is to be introduced by synthesis then one of several different techniques must be applied

- The reagent or reactant may contain a chiral auxiliary, a group in the vicinity of the reaction site that controls the stereochemistry and which is easily removed afterwards, or
- A homochiral catalyst may be used, which can be an enzyme or a synthetic product, or
- A readily available homochiral molecule, often from a natural source, may be incorporated as a building block—the 'chiral pool' approach

Examples of these are shown in Fig 2 The first two are examples of true asymmetric synthesis because chirality is created in the course of reaction, and we will concentrate on such approaches here

The advances in chemical methods of asymmetric synthesis over the past five years[5-7] have been such that the enantiomer excess (% desired −% undesired enantiomer) achieved in a good asymmetric synthesis can be >99%, and 95% is fairly routine Such successful asymmetric syntheses require that information is transmitted efficiently from a pre-existing homochiral source to the reaction site This molecular recognition process involves a combination of attractive forces (electrostatic or van der Waals) and steric repulsion

A high proportion of recent asymmetric syntheses use organometallic or coordination chemistry There are several reasons for this—in particular the ability of metals to complex with the common functional groups in organic molecules in a reversible manner, and the ability to activate simple reactants such as hydrogen and carbon monoxide Also, the reactive complexes are well defined spatially, which is vital for stereochemical control Physicochemical techniques that can elucidate three-dimensional structure are therefore important in developing our understanding of asymmetric synthesis, which is in essence a phenomenon of chemistry in the third dimension Solution spectroscopic techniques, especially nuclear magnetic resonance, are used to some extent X-ray crystallography, however, is still the most important tool, even though asymmetric reactions normally take place in the liquid phase so that an extrapolation from the solid structure is required

Homochiral reagents and auxiliaries

Chirality does not occur spontaneously, it must be imposed during synthesis In general this is achieved using a tightly

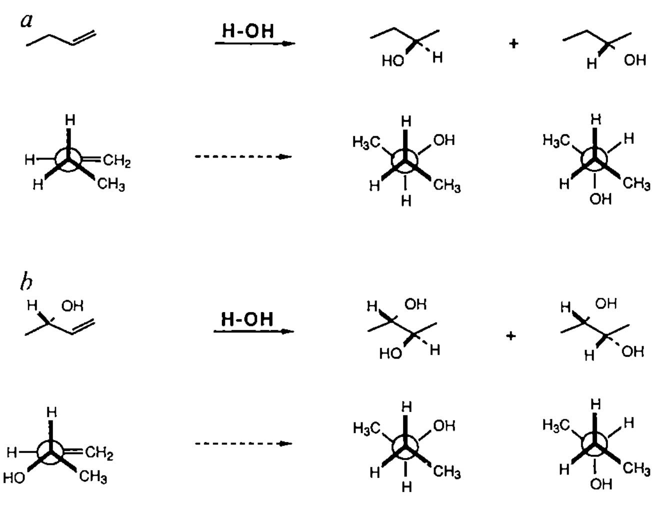

FIG 1 Stereochemistry of hydration of *a*, but-1-ene and *b*, homochiral 3-hydroxybut-1-ene

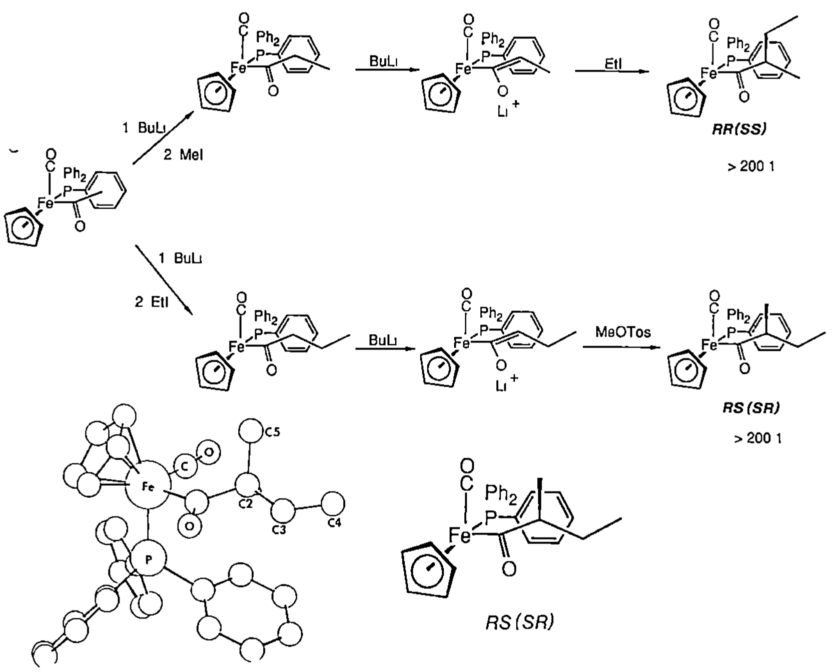

FIG 4 The alkylation pathways for iron enolate complexes, an X-ray crystal structure of the lower product indicating the stereochemistry at C_2 is shown Bu, butyl is C_4H_9, Tos, *p*-toluensulphonyl is $C_7H_7SO_2$

monoxide (very small) This difference in bulk of the ligands in the auxiliary orientates the attached acetyl ligand so as to minimize steric interactions The preferred orientation places the small (relative to methyl) oxygen atom of the acetyl anti to the carbon monoxide ligand, that is, between the large and medium groups (Fig 3) The triphenyl phosphine ligand arranges its phenyls, again to minimize mutual steric interactions, in the form of a rotor Although this rotor is freely rotating, one blade (phenyl group) shields, at all times, one face of the acetyl group (Fig 3) whereas the other face is essentially unencumbered The acetyl group is thus in a fixed orientation in a chiral environment ready for reagents and reactants to approach only from the unhindered face These ingredients are all that are required to impose stereocontrol and achieve asymmetric synthesis

Protons on carbons adjacent to carbonyl groups are acidic[9,12], so removal of a proton from the acetyl, to generate an enolate, is readily achieved with strong base (butyl lithium) Trapping this enolate, which is nucleophilic at the carbon, with the electrophile ethyl iodide forms a new carbon–carbon bond Overall the acetyl group has been converted to the four-carbon butanoyl fragment (Fig 4) The butanoyl group prefers to orientate itself with the terminal two-carbon fragment as far away from the very bulky auxiliary as possible, this exposes only one of the remaining two acidic protons to base Removal of an acidic proton from the butanoyl group generates the corresponding enolate with the ethyl group *cis* to the enolate oxygen Trapping this enolate with the electrophile methyl iodide forms a new carbon–carbon bond and generates the 2-methylbutanoyl complex (Fig 4) The addition of the methyl group can only occur from the unhindered face of the enolate thus giving rise to the stereocontrolled formation of a new chiral centre Figure 4 also shows the X-ray crystal structure of the product 2-methylbutanoyl complex The chiral auxiliary maintains the same structural features as before Looking at this structure, it should be easy to envisage the controlled construction of the chiral centre The final step involved the formation of the C_2–C_5 bond with C_5 approaching C_2 away from the triphenylphosphine and C_3 and C_4 away from the iron Overall two of the hydrogens of the original acetyl group have been replaced sequentially by different organic fragments The method is very versatile, the stereocontrol is very good and the enantiomer produced for a given enantiomer of the chiral auxiliary depends only on the

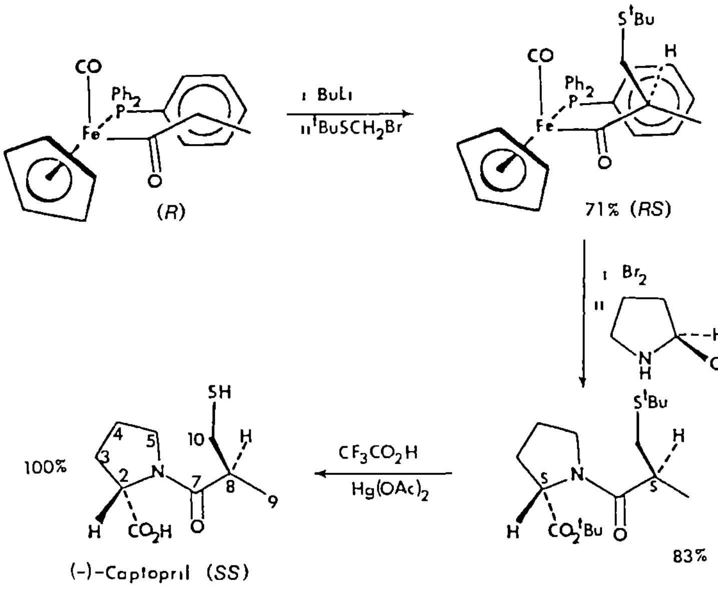

FIG 5 The iron acyl route to *SS*-captopril Ac, acetyl is $COCH_3$

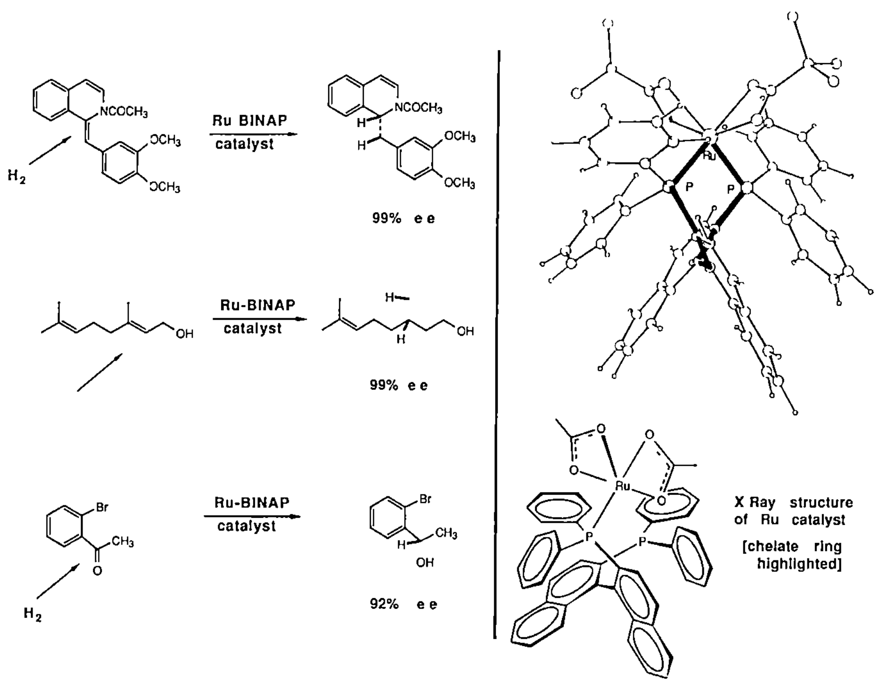

FIG 6 Ruthenium asymmetric hydrogenation with the BINAP complex shown e e, enantiomer excess

sequence of the carbon–carbon bond forming steps

Removal of the chiral auxiliary is readily achieved by one-electron oxidants such as bromine Oxidation in the presence of water, alcohols or amines leads to the formation of carboxylic acids, esters and amides respectively The stereochemical integrity of the new chiral centre is not compromised in the release from the chiral auxiliary[8–10]

The asymmetric synthesis of (−)-captopril is illustrated in Fig 5 Starting from the parent iron acetyl complex the required chiral centre is constructed as before by the sequential introduction of a methyl and a protected thio hydroxymethyl group Removal of the auxiliary in the presence of the *t*-butyl ester of L-proline forms the required amide bond to yield doubly protected captopril Simple deprotection releases (−)-captopril that is identical in all respect to an authentic sample

Homochiral catalysts

Enzymes in synthesis Although we focus on chemical rather than biochemical methods, we consider the latter briefly here Purified enzymes can catalyse the right asymmetric syntheses with near-perfect specificity This applies not only to their natural substrates but to reactants with sufficient structural similarity that the active site recognizes them in the same way Because many important enzymes are readily available—hydrogenases($C{=}O \rightarrow CHOH$), esterases($COOR \rightarrow COOH$) and aldolases($RCHO \rightarrow RCH(OH)CH_2COR'$), for example—biocatalysis will have a significant role in the development of asymmetric synthesis[13–18] At present the limitations are twofold first, the range of substrates is constrained by the natural function of the enzyme, second, the reaction must normally (but not always) be carried out in dilute aqueous solution It is a rapidly developing area, and site-specific mutagenesis may help to diminish these limitations

Asymmetric hydrogenation[19,20]**.** Among reactions catalysed by transition-metal complexes, the addition of hydrogen to multiple bonds is both the most widely used and the best understood Before 1970 G Wilkinson and co-workers had demonstrated that rhodium phosphine complexes were efficient catalysts for

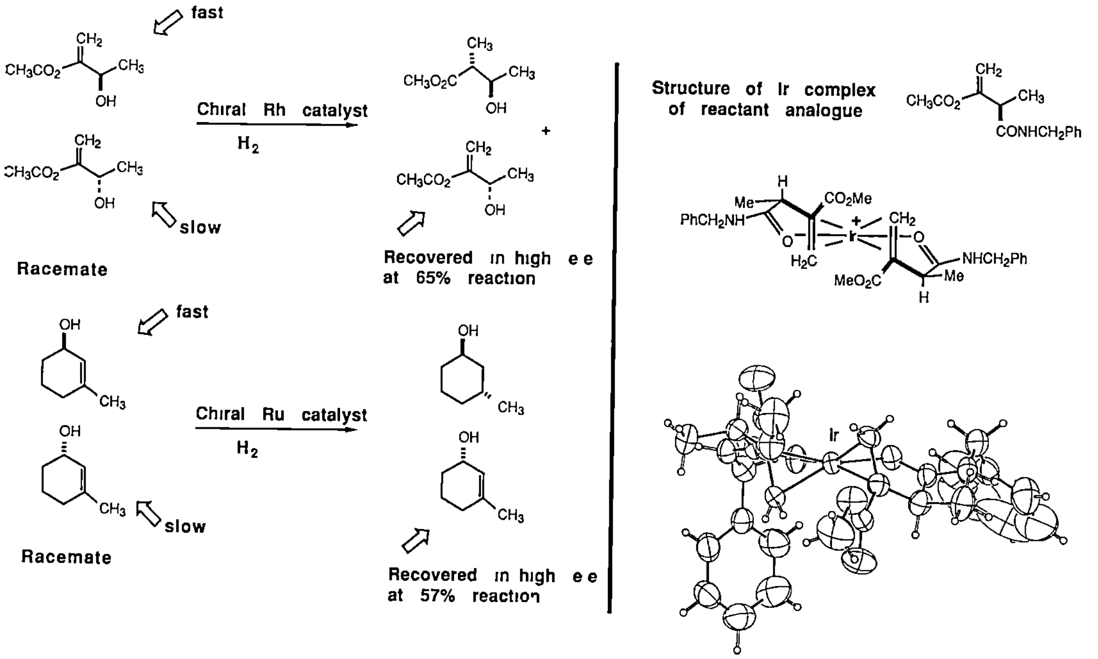

FIG 7 Catalytic kinetic resolution in hydrogenation with rhodium and ruthenium complexes

he reaction in organic solvents[21] The development of homogeneous hydrogenation was a principal factor in the award of he 1973 Nobel prize to Wilkinson Many groups realized he potential of this reaction in asymmetric synthesis By 1977 t had been discovered that the double bond of dehydroamino acids could be hydrogenated to one enantiomer of the amino acid with essentially complete specificity The critical insight, for which major credit must be given to H B Kagan and W S Knowles, was the possibility of using chelating biphosphines as chiral ligands[19,20] The recognition process involves coordination of the dehydroamino acid (introduced as an amide) to hodium through both the olefin and amide group The presence of a secondary binding site is a familiar concept to enzymologists and it proves to be a critical feature for asymmetric synthesis Thus rhodium asymmetric hydrogenation is not a general reaction—substrates that lack secondary binding are not reduced with high enantioselectivity Nevertheless, this reaction remains one of the best chemical routes to optically pure amino acids of D- or L-configuration and was used in an industrial-scale synthesis of L-DOPA (for clinical treatment of Parkinson's disease) for several years Many homochiral ligands are effective provided that they can form chelates, and they probably operate by a common mechanism[20]

The next major breakthrough came in 1986-7 In early work, Wilkinson, James and others had shown that ruthenium complexes were effective for the catalytic hydrogenation of simple olefins[21] The field was not developed to the same extent as rhodium catalysis until the group led by R Noyori prepared ruthenium complexes of the homochiral ligand BINAP (most ligands for asymmetric catalysis have unwieldy chemical names so acronyms are used) These have proved to give extraordinary specificity for a broad range of asymmetric reductions[22 23] The reaction is not confined to olefins, for many unsymmetrical ketones can be hydrogenated to homochiral alcohols Some typical reaction sequences are illustrated in Fig 6, along with a crystal structure of the catalyst precursor, a biphosphine ruthenium bis-acetate The reason for its efficacy is not yet properly understood, but the ligand can be viewed as a chiral scaffold, with the P-aryl rings rather rigidly defined in space, occupying two coordination sites of hexacoordinated ruthenium In the catalytic cycle the acetates are displaced so that four coordination sites are made available Three sites are taken up by two adjacent hydrides and by the auxiliary binding group The remaining site is available for the olefin or ketone such that only one of its two faces can be accommodated, leading to the observed specificity

Catalytic kinetic resolution[24] The examples of asymmetric hydrogenation given above involved substrates that have an auxiliary binding group in the vicinity of the reduction site If this is itself at an asymmetric centre, then further stereochemical control can be exercised With any catalyst, chiral or otherwise, the new asymmetric centre may bear a defined stereochemical relationship to the existing one—the binding group may direct the course of reduction The cationic rhodium complexes that are effective for asymmetric hydrogenation also work well in such directed hydrogenations, with better than 99% of one diastereomer produced[25,26] Further, the substrate tolerance is much greater than in the former reaction, so that hydroxy, carboxy and acylamino are all efficient directing groups

The course of these directed hydrogenations is controlled by steric effects that result because of the binding to rhodium The result can be predicted from molecular models which clearly show that coordination of one face of the olefin is strongly unfavourable on steric grounds The idea is reinforced by an X-ray structure of a typical reactant coordinated to iridium—it has the same relative configuration as the product of directed hydrogenation (Fig 7) (N W Alcock, J M B, A Conn, A P James and R J Taylor, manuscript in preparation)

If the chiral starting material is racemic (equal amounts of both hands) and the catalyst homochiral then kinetic resolution may occur This requires that the two hands of substrate react at sufficiently different rates In this case the fast-reacting enantiomer is increasingly depleted as reaction proceeds, and the starting material tends towards optical purity The relative rate of fast and slow-reacting enantiomers is expressed as a selectivity factor *S*, for an *S* value of 50 an enantiomer excess of 95% is obtained at 55% reaction (45% recovery of optically active starting material) whereas an *S* value of 10 leads to an enantiomer excess of 95% at 65% reaction (35% recovery of starting material) For the reductions catalysed by rhodium complexes, shown in Fig 7, *S* values of between 10 and 25 have been recorded, making this an effective route to optically enriched derivatives of acrylic acid, a useful building block in synthesis

The ruthenium complexes discussed earlier have similar efficiency in kinetic resolution of acylates, but require hydrogen pressures greater than 1 atmosphere They can also be used for the kinetic resolution of some simple cycloalkenols (see Fig 7) where the rhodium catalysts are ineffective

Catalytic amplification of chirality The reaction of organometallic reagents with aldehydes is one of the most common methods for the formation of a new carbon–carbon bond It was discovered recently that organozinc reagents such as Et$_2$Zn will

FIG 8 Aminoalcohol-catalysed addition of diethylzinc to aldehydes

add to aldehydes in the presence of a catalytic amount of a β-aminoalcohol[27-30] Further, if the catalyst is homochiral, the resulting secondary alcohol is formed with a high enantiomer excess This proves to be a valuable procedure, especially for aromatic products The catalysts can be derived from the natural products camphor, proline or ephedrine by conventional chemical synthesis

The catalyst for this reaction forms a complex with the organozinc reagent that has been isolated in crystalline form It proves to be a dimer that is characterized by a central core unit—a four-membered ring of alternating zinc and oxygen atoms This dimer possesses a C_2 symmetry axis Noyori's group also prepared the corresponding racemic dimer which has a similar structure but with a plane of symmetry because it contains one molecule of each enantiomer This has also been characterized by X-ray crystallography (Fig 8) In solution, the binding constant for formation of the racemic dimer is very much greater than that for formation of the optically active dimer Conversely, the racemic complex dissociates to monomer much less readily For the catalytic addition reaction, it is the monomeric complex formed by dissociation of the dimer which is the active catalyst Hence the optically active complex is a much more reactive catalyst than the racemic complex

These observations have been exploited in a novel experiment in which chirality is apparently created[31,32] Consider a catalytic zinc complex in which the initial enantiomer excess of the β-aminoalcohol is 10% Most of this will be present in solution as racemic dimer which is a rather unreactive catalyst This leaves a small amount of homochiral dimer which readily dissociates to a reactive catalyst for the aldehyde addition reaction Consequently, the optical yield is almost as high as that obtained with a homochiral catalyst This apparent conjuring trick has no immediate practical importance but may help in the design of the next generation of asymmetric catalysts It has an obvious relevance to the debate on the primordial origins of chirality, because it demonstrates an amplification process with a purely chemical mechanism

The future

The differing pharmacological effects of the two enantiomers of chiral molecules are now well documented Even if the inactive enantiomer lacks undesirable side effects, administering th potent enantiomer alone halves the dose and alleviates stres on the patient's already compromised metabolism We are a the watershed of asymmetric synthesis—in the near future will be common practice to synthesize all potential new drug as single enantiomers and there is already pressure from regulatory agencies in this direction

Although we have concentrated on drugs in the above articl many other exciting applications are unfolding, now that th synthesis of single enantiomers is becoming more general Th bulk properties of polymers constructed from single enantiomer of monomers are very different from those constructed from racemates A requirement of new materials for molecular electronics is that they be non-centrosymmetric This is, b definition, a property of enantiomerically pure materials Futur generations of, for example, optical data storage devices ma depend on enantiomerically pure organic compounds

The recent advances in chemical asymmetric synthesis tha we have reported here need to be compared to enzyme methods in which there have been recent developments in site-directe mutagenesis The two approaches are complementary and wil contribute in distinct ways As a broad generalization, th methods of biotechnology are most suited to the production o natural molecules, or of closely related homochiral compounds and spectacular selectivity can be achieved By contrast, potentially all homochiral compounds are accessible in enantiomerically pure form by chemical asymmetric synthesis

In many ways the chemical methods described here are stil quite primitive There is still much to be learned about th recognition processes which are at the core of asymmetric synthesis, and the trend will be towards tailoring the structure o reagents and catalysts to take account of increased understanding gained through mechanistic, structural and compute modelling experiments The strength lies in versatility, becaus the only constraint on design of these reagents and catalysts i the ingenuity of the research scientist We expect that the nex decade will see advances in chemical approaches to asymmetri synthesis that will outstrip biological methods in terms o efficiency, versatility and output □

J M Brown and S G Davies are at the Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, UK

A 17,000-year glacio-eustatic sea level record: influence of glacial melting rates on the Younger Dryas event and deep-ocean circulation

Richard G. Fairbanks

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964, USA

Coral reefs drilled offshore of Barbados provide the first continuous and detailed record of sea level change during the last deglaciation. The sea level was 121 ± 5 metres below present level during the last glacial maximum. The deglacial sea level rise was not monotonic; rather, it was marked by two intervals of rapid rise. Varying rates of melt-water discharge to the North Atlantic surface ocean dramatically affected North Atlantic deep-water production and oceanic oxygen isotope chemistry. A global oxygen isotope record for ocean water has been calculated from the Barbados sea level curve, allowing separation of the ice volume component common to all oxygen isotope records measured in deep-sea cores.

CHANGES in continental ice volume during the last deglaciation generally have been inferred from two indirect sources: (1) geological mapping of retreating ice margins, and (2) the marine oxygen isotope record. Direct estimates of glacial ice volume based on measured glacio-eustatic sea level changes are well documented from 9,000 years BP (before present)[1], but are poorly constrained before this time. Ruddiman[2,3] recently reviewed evidence supporting three different deglaciation models: (1) the 'smooth deglaciation' model with the most rapid change centred at 11,000 years BP, (2) the 'French two-step' deglaciation model with maximum melting rates from 14,000 to 12,000 years BP and from 10,000 to 7,000 years BP separated by a mid-deglacial pause with little or no ice volume loss, and (3) a 'younger Dryas' deglaciation model, which is distinguished from the French two-step model by a mid-deglacial reversal with significant ice growth from 11,000 to 10,000 years BP. Ruddiman concluded that the available evidence from marine and terrestrial records favoured the smooth deglaciation model. He further suggested that the stepwise decreases of $\delta^{18}O$ $(=([(^{18}O/^{16}O)_{\mathrm{sample}}/(^{18}O/^{16}O)_{\mathrm{standard}}]-1)\times 10^3)$ apparent in many curves may not indicate sudden decreases in ice volume, but instead may be an artefact of a deep-ocean warming.

I sought to test the validity of these models, each with their own important climatic and oceanographic implications, by extending the existing coral-reef sea level curve[1] to the last glacial maximum. The fossil coral reefs surrounding Barbados are a very good system for examining the detail and timing of the last deglaciation. Here I show that the sea level curve derived from the Barbados reefs supports the French two-step model[4]. I then review the evidence for the oceanic and climatic response to this two-step deglaciation, with particular emphasis on understanding the cause of the Younger Dryas event.

Barbados corals

The Caribbean reef-crest coral *Acropora palmata* (Lamarck) is[1,5] the best available sea level indicator for Pleistocene studies. This species is generally restricted to the upper five metres of water and dominates the reef-crest community in many locations. *A. palmata* is one of the fastest growing corals and is often found in an interlocking reef framework on the windward side of Caribbean islands. Its massive size minimizes post-depositional transport and compaction, and its abundance and generally pristine aragonite skeleton make sampling for ^{14}C or $^{230}Th/^{234}U$ age dating relatively easy.

To reconstruct glacio-eustatic sea levels, I chose to core *A. palmata* on the south coast of Barbados for several reasons: (1) the offshore bathymetry is gently sloping compared with the precipitous drop surrounding many Caribbean volcanic islands or the Bahama Bank; (2) Barbados is rimmed by three parallel offshore ridges[6] for which I had extremely detailed bathymetric maps. Macintyre has suggested[6] that these ridges are associated with past sea level changes, comprising potentially thick sequences of *A. palmata*; (3) onshore exposure of the *A. palmata* facies deposited during the penultimate deglaciation[5] (isotope stage 6-5) indicates that the south coast of Barbados is being uplifted at ~34 cm kyr^{-1}. Field mapping of these onshore *A. palmata* deposits indicated that throughout the history of reef growth on Barbados, the most extensive areal and vertical distribution of *A. palmata* occurred on the south and south-east coast; (4) Barbados is located in the western tropical Atlantic where relative sea level is least affected by changes in the equipotential surface that are due to the changing gravitational attraction of the diminishing Northern Hemisphere ice sheet[7]. Possible drawbacks of selecting Barbados include: (1) the assumption that the late Quaternary mean uplift of Barbados is without significant episodic uplift or subsidence; (2) the dip-stick model of using oceanic islands to measure net ocean sea level changes may be too simple or may not apply to Barbados because it is situated on top of an accretionary prism between two oceanic plates. The only adequate way to test these geophysical assumptions is to perform the same drilling and dating experiment at other locations.

Barbados cores and their radiocarbon ages

Between 18 November and 6 December 1988, 16 cores were drilled from the RV *Ranger* offshore of the south coast of Barbados using a wire-line coring rig with a four-point mooring system. The purpose of this cruise was to core a continuous vertical sequence of *A. palmata* deposited during sea level rise associated with the last deglaciation. The stratigraphy of the ten longest cores and the corresponding ^{14}C ages are illustrated in Fig. 1. These results show that a nearly continuous sequence of *A. palmata* was recovered between 7,800 yr BP and 17,100 yr BP.

To help guide site selection three radiocarbon ages were determined while drilling was in progress. The remainder were

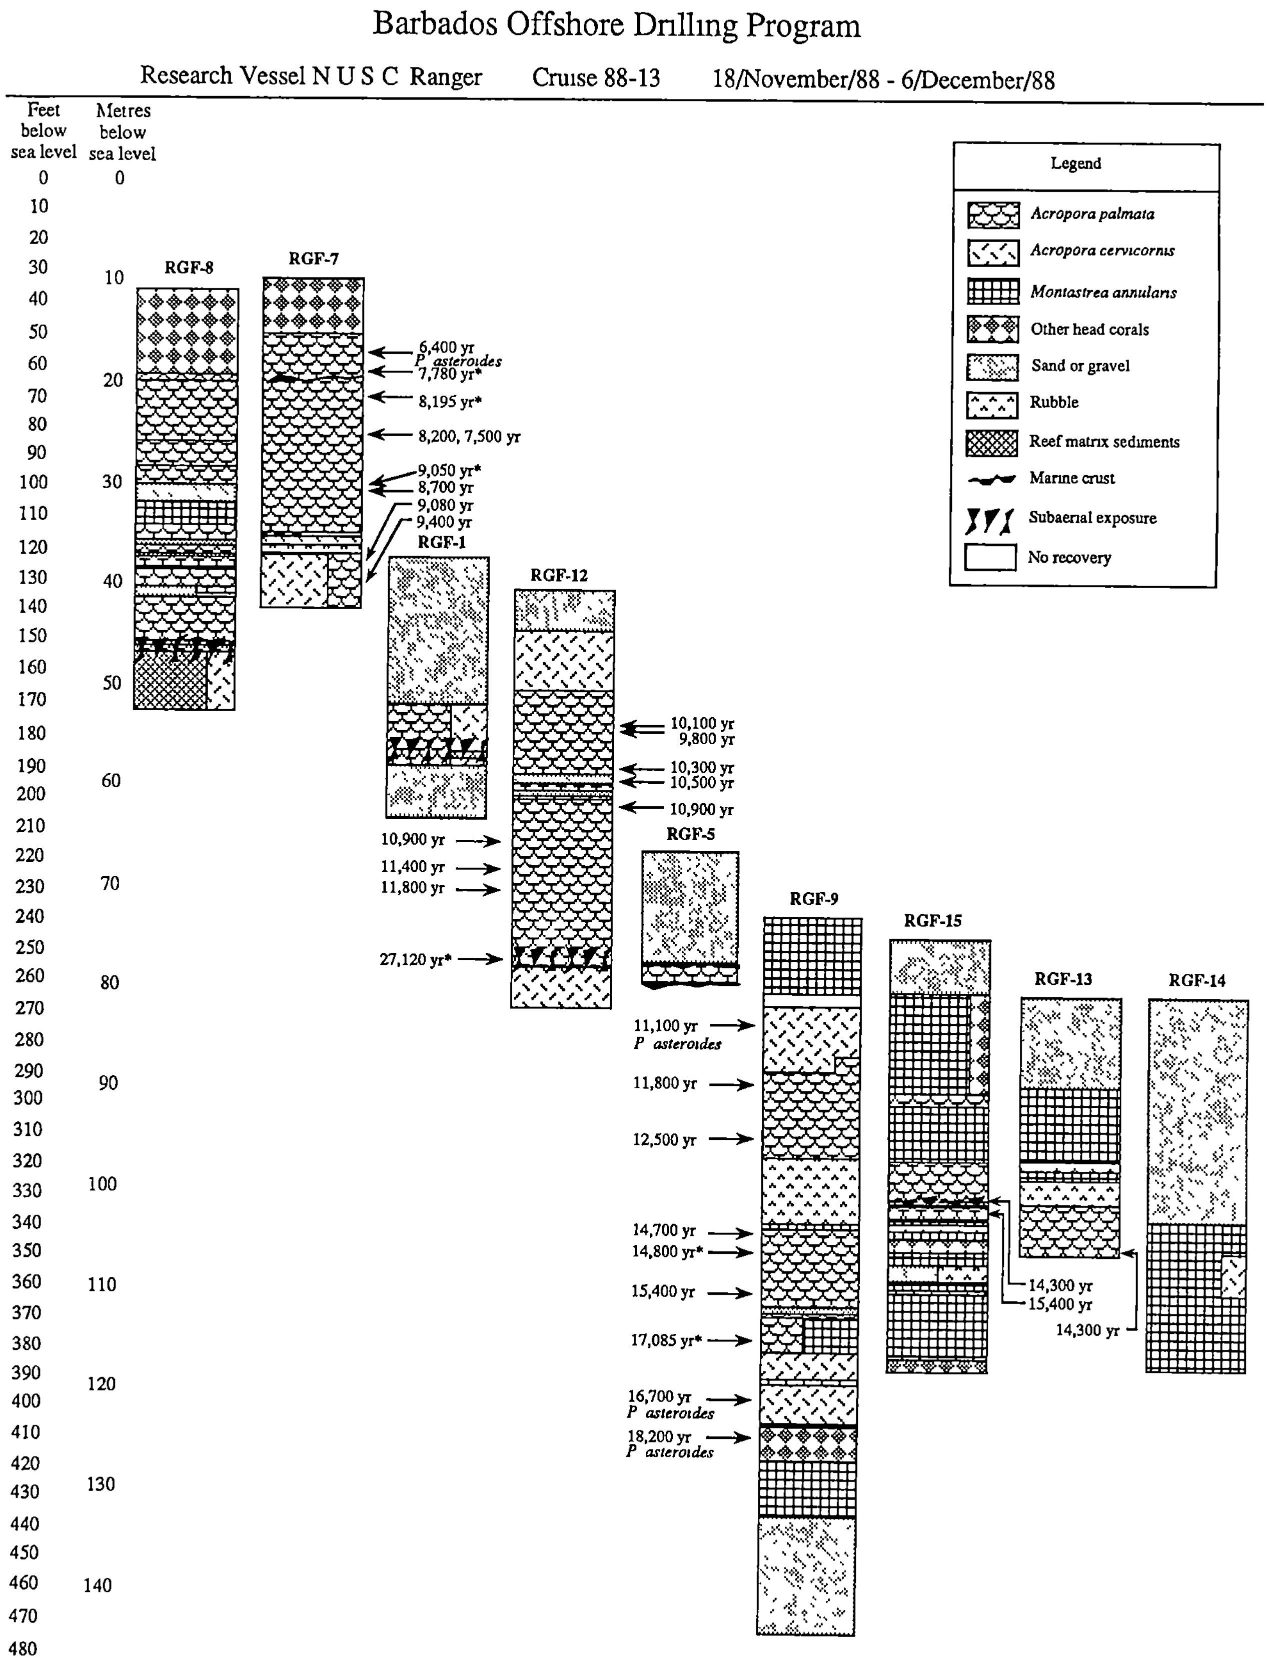

FIG 1 Stratigraphic description of Barbados cores plotted against the modern sea level Radiocarbon ages (yr) of individual corals are indicated by arrows These ages are corrected for local seawater $\Delta^{14}C$ (the difference between the ^{14}C content of air and surface water) by subtracting 400 yr from the measured radiocarbon ages All dated corals are *A palmata* with four exceptions as noted where *P asteroides* were dated Sample at 25 m was dated twice and the 700-yr difference is assumed to arise from a ^{14}C laboratory error The younger age is assumed to be incorrect because it is stratigraphically inconsistent with neighbouring samples This value is therefore not included in Fig 2 Ages marked by an asterisk were measured at Geochron Laboratory, all others at Lamont-Doherty Samples below the subaerial exposure horizons in cores RGF-8 and RGF-1 have been dated at >44,000 radiocarbon years

determined after the cruise using conventional liquid scintillation counting or gas proportional counting The average analytical uncertainty (1σ) of these measurements is ±130 yr for ages less than 17,000 yr All radiocarbon ages are corrected for the apparent age of sea water at Barbados by subtracting 400 yr (ref 8) Radiocarbon ages are not corrected for secular changes in the atmospheric ^{14}C which may be large during the deglaciation[9] As part of a companion study, the ^{230}Th/^{234}U ages of these samples are being determined by mass spectrometry[10] to establish time-dependent changes in the surface ocean ^{14}C levels

The deepest radiocarbon-dated sample of *A palmata* occurs at 113 8 m below the present sea level (119 6 m if corrected for assumed mean uplift rate) and is dated to be 17,100 yr old This age marks the end of the glacial period according to accelerator mass spectrometry (AMS) ^{14}C-dated δ^{18}O records from deep-sea cores[11,12] A sample of *Porites asteroides* from 124 m below the present sea level is 18,200 yr old This date provides a maximum sea level estimate of 131 m (uplift corrected) for the last glacial maximum Unlike *A palmata*, *P asteroides* is not restricted to shallow depths so this glacial maximum sea level estimate must be taken as an extreme Extrapolation of the sea level curve to 18,000 yr BP indicates a sea level of 121 ± 5 m below the present level during the last glacial maximum, the best estimate so far

Between 17,100 and 12,500 yr BP, the sea level increased by 20 m (Fig 2) This first phase of deglaciation was terminated by an exceedingly rapid sea level rise of 24 m in less than 1,000 radiocarbon years, termed melt-water pulse IA (mwp-IA) Melt-water pulse IA (12,000 yr BP) corresponds to the latter part of Termination Ia (14,500–11,500 yr BP) as defined in deep-sea δ^{18}O records (refs 4, 11, later modified in ref 12) Melt-water pulse IA and Termination Ia overlap to some extent, but cannot be synonymous The rate of sea level rise was at a minimum at 11,000 yr BP, marking the beginning of the Younger Dryas chronozone, and remained low until 10,500 yr BP The last half of the Younger Dryas chronozone (10,500–10,000 yr BP) is marked by increasing rates of sea level change, culminating in melt-water pulse IB (mwp-IB) centred at 9,500 yr BP During mwp-IB, which closely corresponds to Termination Ib in deep-sea terminology, the sea level rose ~28 m, similar to the sea level rise associated with mwp-IA

Comparison of seasonal insolation changes

According to the Milankovitch theory[13] the Pleistocene ice ages were caused primarily by changes in the seasonal distribution of incoming radiation associated with orbit variations The Northern Hemisphere ice sheets accumulate in the 40°–70° N latitude range whereas the Antarctic ice sheet is located poleward of 70° S Insolation changes associated with the 41,000-yr tilt cycle increase poleward in both hemispheres, whereas the 23,000-yr precessional cycle dominates insolation changes at middle and low latitudes and is out of phase between hemispheres Since the work of Milankovitch, the time-dependent patterns of radiation have been calculated more precisely[14] The Barbados sea level provides the first direct and high-resolution comparison between the astronomical changes and continental ice response In Fig 3, the changes in insolation over the Laurentide/Fennoscandinavian ice sheet and the Antarctic ice sheet are compared with the melt-water discharge rates calculated from the Barbados sea level curve The discharge rates are plotted in radiocarbon years and must be converted to calender years for comparison with the insolation curves[15] Initial ^{230}Th/^{234}U dates by mass spectrometry indicate that the two melt-water pulses are not artefacts arising from distortions of the radiocarbon timescale (E Bard, B Hamelin and R G F, manuscript in preparation) The ^{230}Th/^{234}U age of mwp-IA is somewhat older, however, than the calibration curve[15] would indicate Although the radiocarbon-age calibration is not well established beyond 9,000 yr BP (ref 15), the absolute-age estimates for the two melt-water pulses are 13,070 and 10,445 calendar years BP based on the ^{14}C calibration of ref 15 This comparison shows that the most intense interval of ice-sheet disintegration (13,070 calendar years BP) predates the Northern Hemisphere insolation maximum (centred at 11,000 years BP) by ~2,000 yr (Fig 3) Melt-water pulse IB is 500 years younger than the insolation maximum At present there is no astronomical explanation for separate melt-water pulses The distribution of Northern Hemisphere ice and the retreat of its margins was not uniform[16], and the relative contribution and timing of Antarctic ice decay is not known These as well as other factors, such as changing ocean and atmosphere circulation patterns, may explain the variable discharge rates

The global oxygen isotope curve

The ^{14}C-dated Barbados sea level curve can be scaled to δ^{18}O using the calibration of 0 011‰ per metre change in sea level[5] (Fig 2) This calibration is a maximum value and corresponds to a mean glacial-ice δ^{18}O value of −42‰ (standard mean ocean water) Based on ice-core δ^{18}O data from Greenland and Antarctica and modern δ^{18}O measurements in precipitation, this value provides a reasonable upper limit for mean ice composition for the entire deglaciation The global δ^{18}O curve predicted from the Barbados sea level curve represents the ice volume component common to all δ^{18}O records from deep-sea cores After taking into account the mixing time of the ocean, the global δ^{18}O curve can be subtracted from any high-resolution AMS ^{14}C-dated δ^{18}O curve to compare regional differences in the δ^{18}O of water and temperature

Ocean δ^{18}O record of melt-water discharge rates

During mwp-IA and mwp-IB, glacial melt water discharged (primarily into the North Atlantic surface ocean) at maximum rates of 14,000 km^3 yr^{-1} and 9,500 km^3 yr^{-1} respectively (Fig 3)

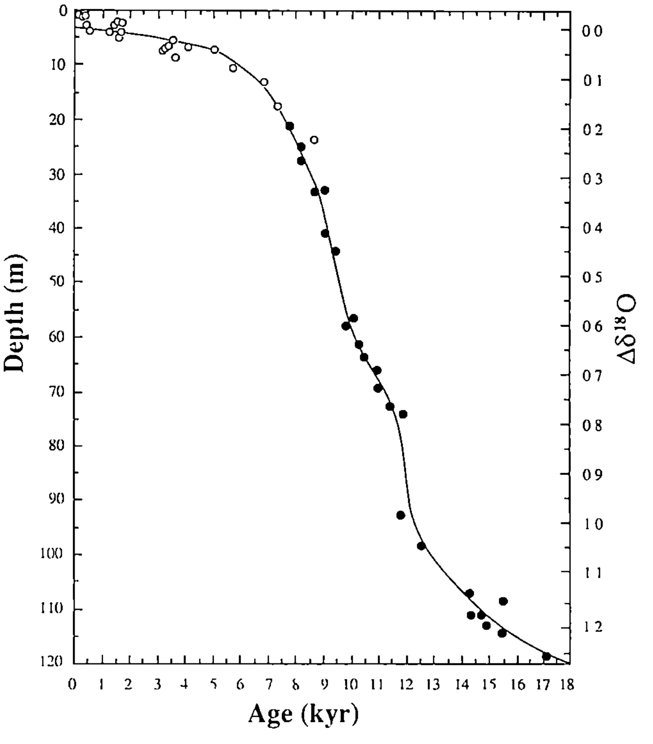

FIG 2 Barbados sea level curve based on radiocarbon-dated *A palmata* (filled circles) compared with *A palmata* age-depth data[1] (open circles) for four other Caribbean island locations All radiocarbon ages in this figure are corrected for local seawater Δ^{14}C by subtracting 400 yr from the measured radiocarbon ages[8] but they are not corrected for secular changes in atmospheric ^{14}C levels[15] The Barbados data are corrected for the estimated mean uplift of 34 cm kyr^{-1} The right-hand axis of the Barbados sea level curve (solid line) is scaled to the estimated δ^{18}O change of mean ocean water using the calibration in ref 5

These glacial-melt-water rates are comparable to the modern fresh-water discharge rate (11,400 km^3 yr^{-1}) into the entire North Atlantic (0–90° N latitude)[17] During the first half of the Younger Dryas chronozone between 11,000 and 10,500 yr BP, melt-water discharge averaged 2,700 km^3 yr^{-1}, a factor of five less than discharge rates during mwp-IA and at least a factor of three less than rates during mwp-IB By comparison, the modern discharge rates for the Mississippi and St Lawrence Rivers are 560 km^3 yr^{-1} and 330 km^3 yr^{-1} respectively[17]

The modern river discharge and marine precipitation is redistributed within the North Atlantic by ocean surface currents and results in strong oxygen isotope gradients of sea water in the north and north-west Atlantic bordering the subtropical gyre Because glacial ice has very low δ^{18}O values relative to sea water, it is reasonable to assume that North Atlantic surface-water δ^{18}O distribution was dramatically affected by the sharp increase in seasonal melt-water discharge during mwp-IA and mwp-IB

The oxygen isotopic composition of planktonic foraminifera is a function of both the ambient seawater oxygen isotopic composition and temperature Foraminiferal species have different seasonal, geographic and vertical distributions whereas melt-water discharge is very seasonal The most extensively dated (AMS ^{14}C) foraminiferal oxygen-isotope record in the North Atlantic is from piston core SU81-18 taken at a depth of 3,135 m near the coast of Portugal (37°46′ N, 10°11′ W)[12] The oxygen isotope record of *G bulloides* shows four distinct steps followed by δ^{18}O minima dated at 13,600, 12,300, 8,800 and 6,800 yr BP (Fig 4) The two largest steps coincide with mwp-IA and mwp-IB Although it is possible that these δ^{18}O shifts with minima at 12,300 and 8,800 yr BP are somehow related to local temperature changes, their coincidence with the salinity (δ^{18}O) minima predicted by the Barbados sea level curve is strong evidence for regional salinity (δ^{18}O) changes I note that lower salinity and warmer temperatures both result in reduced δ^{18}O values of foraminiferal tests Assuming an average glacial melt-water δ^{18}O value of −42‰, then the δ^{18}O of North Atlantic surface water will change at a corresponding rate of −1 2‰ for each 1‰ decrease in salinity Therefore, the δ^{18}O minima in core SU81-18 (Fig 4) can be produced by decreases in salinity of <1‰ The sea level increased only 10 m between 14,300 and 12,500 yr BP, an interval that spans the oldest δ^{18}O minima (13,600 yr) in core SU81-18

Origin of the Younger Dryas event

In the preceding scenario, the Younger Dryas chronozone in the marine realm is characterized by minimal glacial-melt-water discharge, particularly between 11,000 and 10,500 yr BP, and is distinguished as an event primarily by its temporal position between two episodes of lower surface salinity This interpretation of the origin of the Younger Dryas event is fundamentally different from the explanations involving the polar-front movements linked to ice-sheet elevation[2,3,12,18–20] It is the exact opposite of explanations for the Younger Dryas that call upon maximum influxes of glacial ice and water between 11,000 and 10,000 yr BP[18–22]

Apparently there are very different regional responses to the melt-water pulses For example, Mangerud *et al*[23] have shown that in western Norway there were two major glacial re-advances into the North Sea at 12,200 and 10,000 yr BP In the north-east Atlantic, unusually high abundances of the polar species *N pachyderma sin* are found in association with the Vedde ash layer dated at 10,600 years BP (ref 23) This peak abundance of polar species has been interpreted as a Younger Dryas cold event in the north-east Atlantic[18–20] although it apparently coincides with a low melt-water discharge rate Ruddiman *et al*[8] concluded that the Vedde ash, such as found at core site V23-81 on the Feni Drift, was delivered to the north-east Atlantic

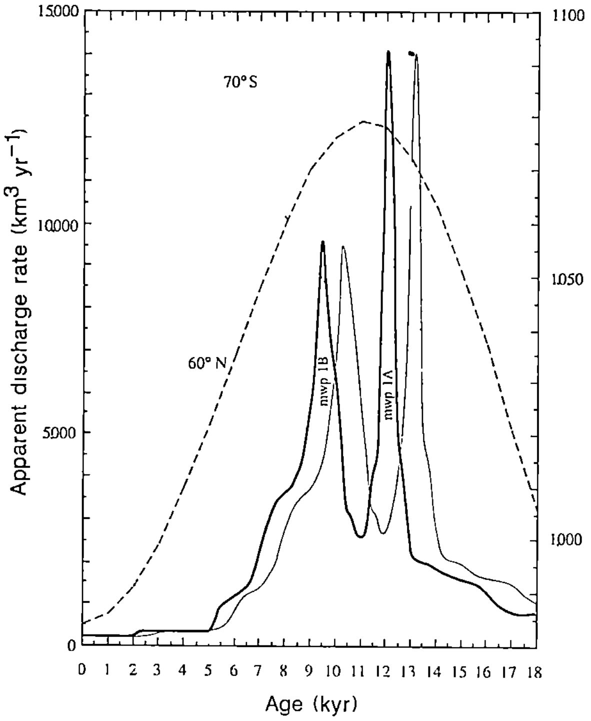

FIG 3 The rate of glacial melt-water discharge calculated from the Barbados sea level curve compared to summer insolation The discharge curve (thick line) is plotted according to radiocarbon years uncorrected for secular changes in atmospheric ^{14}C Converting radiocarbon years BP to calendar years BP using the calibration in ref 15 shifts the ages of mwp-IB and mwp-IA as shown by the thin line Our preliminary ^{230}Th/^{234}U dates indicate that this correction is too small for mwp-IA (E Bard, B Hamelin and R G F, manuscript in preparation) By comparison, the insolation at 60° N (dashed line) and 70° S latitude (dotted line) are plotted against absolute time[14]

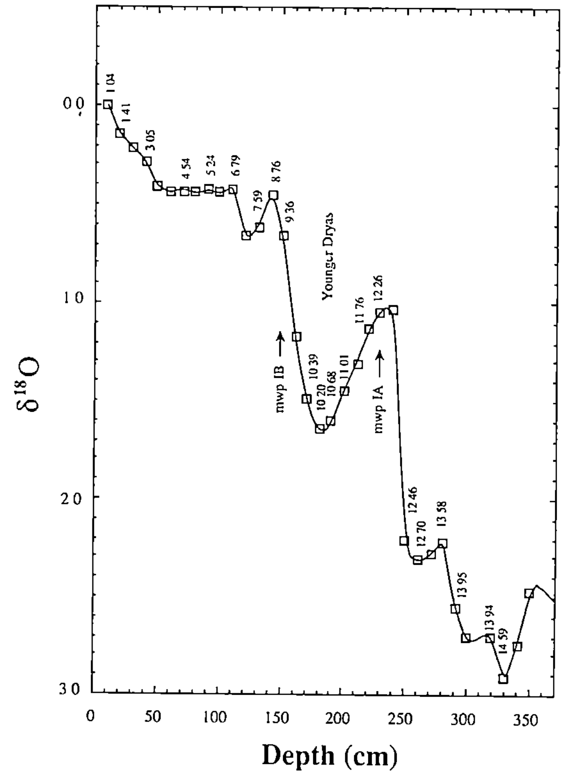

FIG 4 The AMS ^{14}C-dated oxygen isotope record of *G bulloides* from core SU81-18 located offshore of Portugal[12 34] The AMS-^{14}C ages have been corrected for local seawater Δ^{14}C by subtracting 400 yr from the measured radiocarbon ages[8] The estimated depth of mwp-IA and mwp-IB are marked by arrows

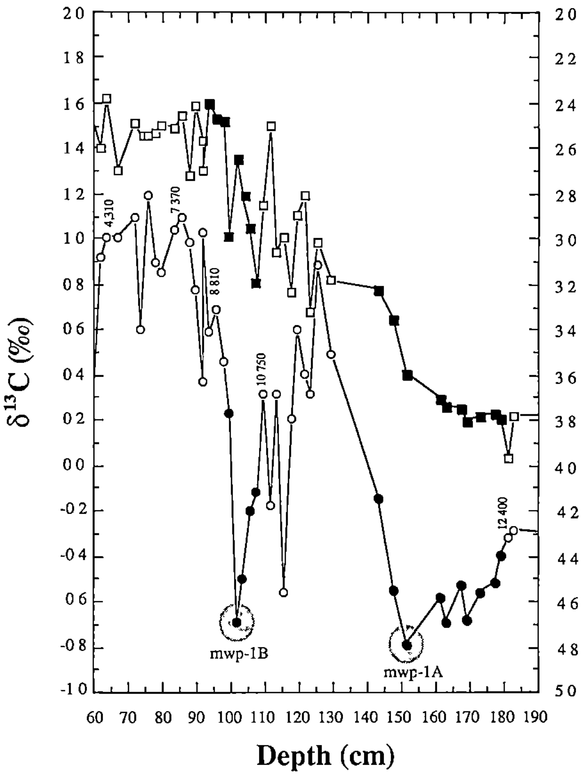

FIG 5 Oxygen and carbon isotope data from core EN120GGC1[29] for the last deglacial interval Age assignments are based on four AMS-^{14}C dates from a companion core that has been stratigraphically correlated to EN120GGC1[30] Using this age model, δ^{13}C minima are approximately coincident with mwp-IA and mwp-IB Closed symbols mark intervals around mwp-IA and mwp-IB and illustrate that δ^{13}C minima occur during the unidirectional shifts in δ^{18}O

by sea ice originating in the Norwegian Sea Recent sea-ice studies[24] show, however, that it is plausible that the *N pachyderma sin* was also imported to the north-east Atlantic by entrapment in sea ice that had formed in the Norwegian Sea

Lower surface-water salinities during mwp-IA and IB are not inconsistent with the faunal distributions in the north-east Atlantic described in, for example, ref 18 Polar station PAPA, at 50° N latitude in the northeastern Pacific, has a low-salinity mixed layer and may be a good analogue for the North Atlantic at 12,000 and 9,500 yr BP Today at station PAPA, an 8 °C seasonal warming of the thin mixed layer results in a seasonal succession of planktonic foraminiferal species from polar to subpolar assemblages[25] Lower salinity might also help explain the evidence for warmer climates on the southern European continent during the Bølling–Allerød and Preboreal periods (see ref 12 for a review) Lower surface salinities generally result in a thinner surface mixed layer with less thermal inertia Energy-balance climate models show[26] that a thinner surface mixed layer in the North Atlantic (>40° N) leads to warmer surface temperatures over land in summer and fall Much larger regional responses over Western Europe are predicted in three-dimensional global-climate-model simulations[26] Conversely, the lack of melt-water stratification of North Atlantic surface waters during the Younger Dryas would allow a return to cooler deglacial conditions recorded by planktonic foraminifera in the North Atlantic ~10,600 yr BP (refs 19, 20, 27) and by western European continental vegetation

Broecker *et al*[27,28] dated the minimum δ^{18}O value (maximum melt-water discharge) in the Gulf of Mexico cores EN32-PC6 and EN32-PC4 at 11,840 and 12,000 yr BP, which are equivalent in age to the AMS ^{14}C-dated δ^{18}O minimum in North Atlantic core SU81-18 (12,260 yr BP)[12] These two events correspond precisely with mwp-IA, dated at 12,000 yr BP (Fig 3) Broecker *et al*[27,28] noted that the maximum glacial-melt-water discharge from the Mississippi River was followed by minimal discharge between 10,500 (EN32-PC6) and 11,100 yr BP (EN32-PC4). They reasoned that this reduction in Mississippi discharge reflected a shift in the drainage from the Mississippi to the St Lawrence River and was not related to changes in glacial melting rates They further speculated that the melt-water diversion caused a salinity decrease in the North Atlantic strong enough to result in a decrease in North Atlantic deep-water formation during the Younger Dryas A reduction in the heat released from the ocean as the northward advection of subtropical surface waters ceased was associated with the reduced formation of North Atlantic deep water The discharge curve derived from the Barbados sea level curve predicts a minimum in Mississippi discharge 11,000 yr BP and therefore it is unnecessary to call upon the unusual combination of events required by the model in refs 27, 28 Furthermore, the discharge curve may explain why no melt-water spike was ever identified in the North Atlantic oxygen isotope records corresponding to an assumed diversion of melt water during the Younger Dryas event

Deep-water response to melt-water pulse

Broecker *et al*[27 28] cite Cd/Ca and δ^{13}C data reported from Bermuda Rise core EN120GGC1[29] as evidence that melt water shut down the production of North Atlantic deep water during the Younger Dryas Boyle and Keigwin's[29] age model for the deglacial section of core EN120GGC1 is based on linear interpolation between age assignments of 14,000 yr BP for Termination Ia and 8,500 yr BP for Termination Ib as well as correlation of the %CaCO$_3$ record with that of a neighbouring core that has two AMS ^{14}C dates on the deglaciation These ages for Terminations Ia and Ib were taken from the AMS ^{14}C dates on North Atlantic core CH73-139C[11] AMS ^{14}C studies on other cores have shown that core CH73-139C suffers from considerable bioturbation[12] The revised ages for Termination Ia are 14,500–12,260 yr BP and for Termination Ib, 10,390–9,360 yr BP (ref 12)

Applying a more accurate chronology to core EN120GGC1[30] shows that the two intervals of highest melt-water discharge are also characterized by extremely low δ^{13}C values, presumably because of reduced influence of North Atlantic deep water at this site (Fig 5) The section corresponding to Younger Dryas interval begins with high δ^{13}C values which then decrease to a minimum value during Termination 1b If this revised timescale for core EN120GGC1 is accurate, then the Younger Dryas and Preboreal chronozones are so condensed that bioturbation must be considered as a significant influence The fact that a relatively subtle adjustment of age assignments can alter the interpretation of deep ocean response to deglaciation emphasizes the necessity for AMS ^{14}C dating of splits of the same samples used for stable isotope and Cd/Ca measurements in core EN120GGC1 Until this is done, it is equally plausible to suggest that the production of North Atlantic deep water was reduced or shut down within the Bølling/Older Dryas (mwp-IA) and Preboreal (mwp-IB) chronozones and not during the Younger Dryas

Continental record of melt-water discharge rates

The rapid disintegration of the Northern Hemisphere ice sheets during mwp-IA and mwp-IB must have introduced large volumes of low-δ^{18}O melt water into the North Atlantic during the summer season This δ^{18}O-spiked melt water has two possible fates entrainment in North Atlantic deep water or evaporation[17] Because deep-water formation may have been halted briefly during the peak discharge, evaporation of δ^{18}O-spiked surface water must have occurred to some extent

The Greenland ice cores Dye 3[31-33] and Camp Century are both marked by two distinct δ^{18}O minima during deglaciation (Fig 6) Many researchers assumed that these δ^{18}O minima indicated cooler temperatures[29-32] and that they were associated with a southward migration of the North Atlantic polar front[19,20] However, recent ^{14}C dating of air bubbles in the Dye 3 ice core[33] enables a direct comparison to the ^{14}C dated Barbados sea level curve (Fig 6) Six AMS ^{14}C measurements were made on samples taken at depths between 1,660 and 1,780 m (ref 33) Using the age-depth relationship (squared correlation coefficient = 0 93) determined from these data, the estimated age for the δ^{18}O minimum at 1,792 m (Fig 6) is 9,320 ^{14}C-years BP The age of this δ^{18}O minimum in Dye 3 matches the age for mwp-IB (9,500 ^{14}C-years BP) It is not clear whether the ^{14}C age is concordant with the estimated calendar age based upon annual layer counts[31], because the radiocarbon timescale is not well calibrated in this time range I believe that these presumed temperature minima in the Greenland δ^{18}O records may in fact be the result of source-water variability as well as temperature If so, they may be the terrestrial equivalents of δ^{18}O minima in deep-sea cores such as SU81-18 (Fig 4)

The immediate implications of the Barbados sea level record compel us to re-evaluate some of the traditional depictions of the Younger Dryas event Whether or not the reinterpretations presented here are correct depends on the reliability of correlations between radiocarbon-dated marine and terrestrial signals My results emphasize the primary role of melt-water discharge rates on the production of North Atlantic deep water and rapid climate change in western Europe ☐

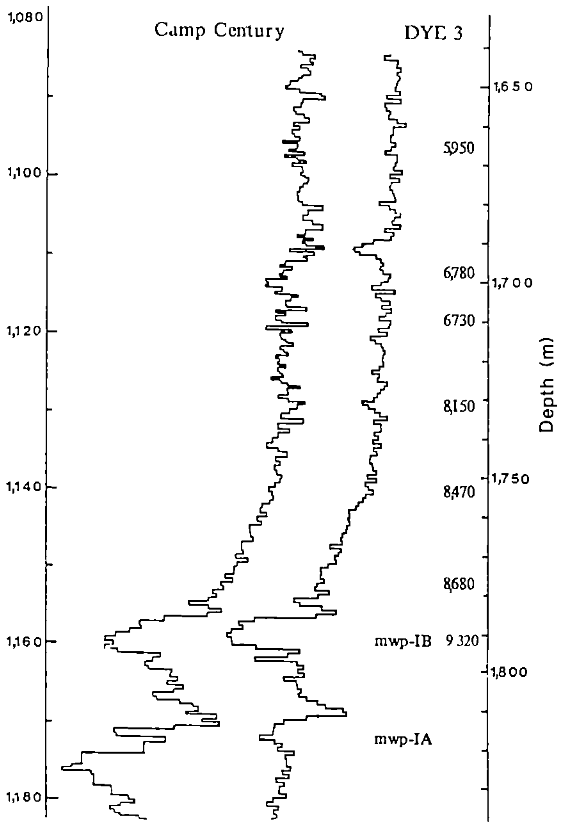

FIG 6 Plot of terrestrial δ^{18}O records from Greenland ice cores Dye 3 and Camp Century[31 32] with six radiocarbon ages[33] indicated for Dye 3 Age for mwp-IB is estimated from the ^{14}C-depth relationship[33]

Cloning by functional expression of a member of the glutamate receptor family

Michael Hollmann, Anne O'Shea-Greenfield, Scott W. Rogers & Stephen Heinemann

Molecular Neurobiology Laboratory, The Salk Institute for Biological Studies, La Jolla, California 92037, USA

We have isolated a complementary DNA clone by screening a rat brain cDNA library for expression of kainate-gated ion channels in Xenopus oocytes The cDNA encodes a single protein of relative molecular mass (M_r) 99,800 which on expression in oocytes forms a functional ion channel possessing the electrophysiological and pharmacological properties of the kainate subtype of the glutamate receptor family in the mammalian central nervous system

THE synapse plays a key role in the nervous system, and it is likely that biochemical changes at the synapse underlie some aspects of higher brain function Most plausible theories of learning, for example, depend upon changes in the efficiency of chemical synapses[1,2] Glutamate receptors are believed to play a central part both in memory aquisition and the establishment of "topographical maps"[3,4] Hence, this receptor family has become the focus of much experimental work Glutamate receptors are found throughout the mammalian brain and represent the predominant excitatory neurotransmitter system[3] The best-studied glutamate receptors are ligand-gated ion channels that are permeable to cations Based on pharmacological and electrophysiological data these receptors have been classified into four main subtypes NMDA (*N*-methyl-D-aspartate), quisqualate, kainate and 2-amino-4-phosphonobutyrate[5] (APB) Recently, a G protein-coupled glutamate receptor representing a fifth class with a very different mechanism of action has been identified[6] The fact that the subtypes show differences in their distribution in the brain[7] indicates that they represent distinct gene products with unique structures and functions

Despite the prominent part these receptors play in normal synaptic transmission as well as in neuronal plasticity, their molecular characteristics have remained elusive, mainly because of a lack of ligands that bind irreversibly and with high specificity Conventional biochemical approaches to the isolation of these receptors have so far either not succeeded in progressing beyond crude receptor solubilization, as is the case for the NMDA[8] and quisqualate[9] subtypes, or have resulted in the isolation of ligand-binding proteins for kainate[10-12] or glutamate[13,14] whose functions remain unclear To circumvent these problems, we adopted a different approach involving the use of an oocyte expression system[15] to guide the selective cloning of cDNAs encoding functional glutamate-gated ion channels

Here, we report the isolation of a cDNA clone, GluR-K1, from a rat forebrain cDNA library This clone, on transcription *in vitro* and injection into *Xenopus* oocytes, expresses a functional glutamate receptor with the pharmacological properties of the kainate subtype The primary structure of the protein encoded by the GluR-K1 cDNA has been deduced, and it is compared with the sequences of other ligand-gated ion channels, the nicotinic acetylcholine receptors (nAChR), and the glycine and γ-aminobutyric acid ($GABA_A$) receptors The pattern of distribution of GluR-K1 mRNA is described and compared with kainate binding sites in the brain

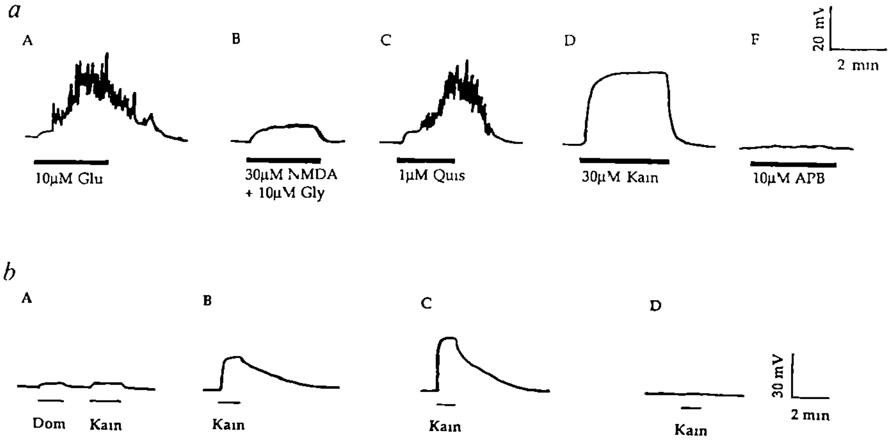

FIG 1 *a*, Voltage traces obtained from a single *Xenopus* oocyte injected with 75 ng poly(A)$^+$ RNA isolated from rat forebrain 2 days before recording Bars indicate duration of superfusion with indicated agonists Glu, L-glutamate, NMDA, *N*-methyl-D-aspartate, Gly, glycine, Quis, quisqualate, Kain, kainate, APB, 2-amino-4-phosphonobutyrate *b*, Voltage recordings from *Xenopus* oocytes 10 days (trace A) or 3 days (traces B–D) after injection with 25 ng λZAP RTB1 sense *in vitro* RNA (total library of 850,000 independent clones) (A), 25 ng λZAP-GluR-K1 sense *in vitro* RNA(B), 1 25 ng of pGluR-K1 sense *in vitro* RNA(C) or 1 25 ng of pGluR-K1 antisense *in vitro* RNA(D) Dom, domoate (10 μM), Kain, kainate (100 μM) Bars indicate duration of superfusion with agonist

METHODS RNA was isolated from rat total forebrain by the guanidine isothiocyanate method[39] and subsequently poly(A)$^+$ selected[40] The Uni-Zap™ XR cloning kit from Stratagene was used to construct a directional cDNA library of 850,000 independent clones in the bacteriophage expression vector λZAP II, where the insert clones are flanked by T3 and T7 RNA polymerase promoters at their 5′ and 3′ ends, respectively, allowing sense as well as antisense transcription[41] DNA from pools of phage clones was linearized with Xho I, and diguanosine triphosphate-capped RNA was synthesized *in vitro* using the RNA transcription kit from Stratagene A DNAse I digest was performed to remove the template after synthesis *Xenopus* oocytes were prepared as previously described[33] and injected with 1–100 ng RNA, usually in a volume of 50 nl Injected oocytes (20 per batch of RNA to be tested) were maintained in daily changed Barth's saline[33] at 17 °C During the initial stages of the library screening, oocytes were checked for responses after 3, 5, 7, 9 and 10 days During later stages of the screening, recordings were made on days 3 and 5 after injection To facilitate rapid, sensitive screening of large numbers of oocytes we used voltage recording rather than voltage clamp, as described previously[33] Depolarizations as small as 1–2 mV could be measured reliably

Isolation of clone λZAPII-GluR-K1

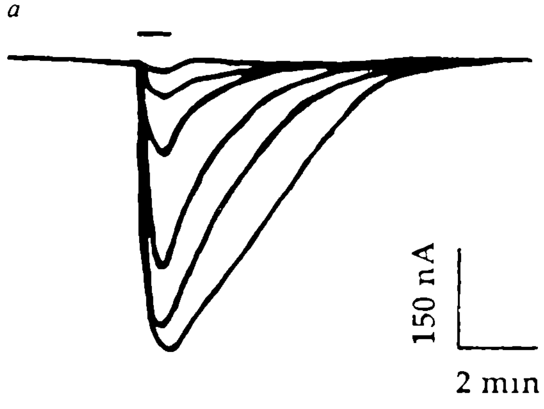
Xenopus oocytes were injected with poly(A)$^+$ RNA isolated from rat forebrain, 2-10 days after which the oocytes were tested electrophysiologically for their ability to respond to selective agonists for glutamate receptor subtypes Depolarizations induced by both glutamate and quisqualate displayed a biphasic pattern composed of a fast-acting, smooth, presumably ligand-gated, ion channel response and a longer lasting, fluctuating response that was probably second-messenger mediated[16] (Fig 1*a*, traces A, C) NMDA and kainate elicited smooth responses with fast onsets (Fig 1*a*, traces B, D) APB gave no response (Fig 1*a*, trace E)

A directional cDNA library (λZAPII RTB1, complexity, 8 × 10^5 elements) consisting of 18 independent sublibraries each of 44,000 clones was constructed from this poly(A)$^+$ RNA using the bacteriophage expression vector λZAPII A pool of *in vitro* transcripts made separately from all 18 amplified sublibraries was injected into oocytes Small depolarizations (1-3 mV) were seen in voltage recordings from oocytes challenged with 100 μM kainate 10 days after injection (Fig 1*b*, trace A) No responses to NMDA or quisqualate were detected Neither normal oocytes nor water-injected oocytes showed any response to glutamate receptor agonists Subsequently, pools of 44,000, 4,000, 400 and 40 clones were tested and in each of these tests at least one pool responded to kainate To ensure throughout the screening procedure that the very small responses observed initially were not recording artefacts, we showed that (1), responses in a given oocyte were reproducible, (2) responses were fast (within one second of agonist application), (3) responses were readily reversible on superfusion of the oocyte with control Ringer solution, and (4) domoate (10 μM) gave a response similar to the one elicited by 100 μM kainate The pools yielding the largest responses at each stage were selected for further subdivision The clones in the final positive pool of 40 clones were analysed for their insert size, and the 12 clones with the largest inserts (all >2 kilobases (kb)) were tested individually for their ability to direct the synthesis of a functional kainate receptor Only one clone, λZAPII-GluR-K1, carrying a 3-kb insert, was found to elicit kainate responses in oocytes (Fig 1*b*, trace B)

Characterization

The plasmid pGluR-K1 was rescued from bacteriophage λZAPII-GluR-K1 and, on transcription *in vitro*, sense RNA (but not antisense RNA) induced kainate responses when injected into oocytes (Fig 1*b*, traces C, D) As little as 10 pg of GluR-K1 sense transcript under voltage-clamp conditions (−70 mV holding potential) gave detectable responses to 100 μM kainate To rule out the possibility that GluR-K1 encoded a transcription factor, oocytes injected with pGluR-K1 *in vitro* transcripts were kept in medium supplemented with 50 μg ml^{-1} actinomycin D to inhibit endogenous transcription[17] These oocytes exhibited the same responses to kainate as those kept in control medium Therefore, injection-induced transcription from the oocyte genome seems unlikely to contribute to the observed responses

L-Glutamate evoked much smaller responses than did kainate, and even at 1 mM, elicited only 50% of the depolarization seen with 30 μM kainate This is consistent with previous reports that glutamate is only a weak agonist for the kainate receptor subtype[3] Other glutamate receptor agonists such as NMDA, quisqualate and L-aspartate evoked no responses when applied at 150 μM, 10 μM and 100 μM, respectively Unrelated neurotransmitter receptor agonists such as glycine, GABA, serotonin and nicotine also failed to evoke responses, even when tested at concentrations as high as 1 mM Glycine did not potentiate the kainate response (data not shown) Dose-response curves for kainate and domoate were recorded (Fig 2*b*), and EC_{50} (effector concentration for half-maximal response) values of



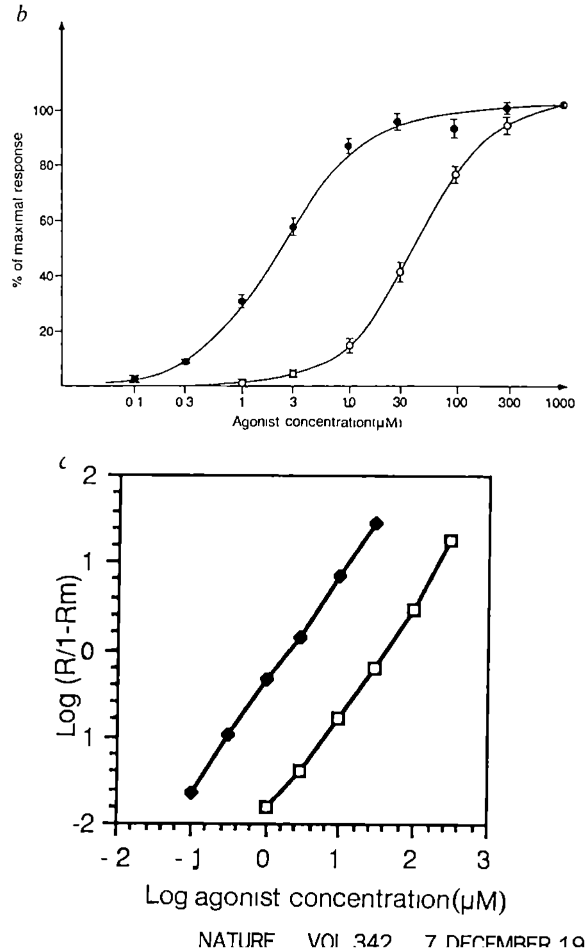


FIG 2 *a*, Superimposed voltage clamp traces, recorded at a holding potential of −70 mV from a single oocytes injected 2 days before recording The oocyte was injected with 1 25 ng pGluR-K1 *in vitro* synthesized RNA transcript, and challenged with increasing kainate concentrations of 1-1,000 μM The agonist was applied for 40 s, followed by control Ringer superfusion Intervals between applications were 5 min Note that the responses do not desensitize *b*, Dose-response curves for kainic acid and domoic acid, recorded as in *a*, each point represents the mean ±s e m of three responses, measured in different oocytes The EC_{50} values derived from these curves are 39 μM and 1 8 μM for kainic acid and domoic acid, respectively Closed circles, domoate, open circles, kainate *c*, Hill plots for oocyte responses to domoate (closed circles) and kainate (open circles), constructed using the mean values of the data from the dose-response curves of *b* Rm, maximal response, R, response Hill coefficients of 1 23 and 1 24 for kainate and domoate, respectively, were obtained

IETHODS The insert cDNA of the bacteriophage lone λZAPII-GluR-K1 was cut out with *Eco* RI-*'ho* I, blunt-ended and subcloned into the *Sma* I-ite of the bacteriophage vector M13mp19 (ref 2), yielding clones with both orientations of the DNA Overlapping deleted subclones were contructed for each strand orientation using the yclone™ kit from USB Single-strand sequencing y the dideoxynucleotide chain-termination ıethod[43] was done with all (45) subclones, and 0 oligonucleotide primers were synthesized to acilitate sequencing across areas where comressions or gaps were encountered in the equences derived from the deletion subclones omplete sequences for both strands were ıus obtained IntelliGenetics software packages ntelliGenetics version 5 0, and PC/Gene™) were sed for analysing sequences

39 µM and 1 8 µM, respectively, were derived These values were in good agreement with results found in oocytes injected with total poly(A)$^+$ RNA[16 18] Hill coefficients calculated from these curves (Fig 2*c*) were 1 23 and 1 24 for kainate and domoate, respectively, indicating the possible cooperative action of several subunits The average reversal potential extrapolated from current responses to 10 µM kainate obtained at a series of holding potentials between 0 and −130 mV was 10 mV Responses to kainate did not desensitize, not even after prolonged (up to 10 min) superfusion with high concentrations (100 µM) of the agonist These findings are also consistent with earlier reports from experiments with kainate receptors expressed from total poly(A)$^+$ RNA[19] Similarly, the pharmacological profile of GluR-K1 (see Table 1), as revealed by the inhibiting properties of various known glutamate receptor antagonists, is consistent with previous reports for kainate receptors in systems where total poly(A)$^+$ RNA was used as a source of kainate receptor message[16,18] Of all the compounds tested (each at 1 mM), the glutamate receptor antagonist of broad specificity, kynurenic acid, was the most potent inhibitor of the kainate-evoked depolarizations in oocytes injected with GluR-K1 RNA synthesized *in vitro* To a lesser extent, γ-D-glutamylglycine (γ-DGG), reported to block preferentially kainate and NMDA receptors but not quisqualate receptors[20], inhibited kainate responses, as did γ-D-glutamylaminomethylsulphonate (GAMS), which acts preferentially on kainate and quisqualate receptors[21] Similarly, 2,3-*cis*-piperidine dicarboxylic acid (PDA), which is known to block all subtypes of glutamate receptors[5], blocked the GluR-K1 response Glutamate diethylester (GDEE), which is thought to inhibit preferentially quisqualate-type glutamate receptors[5], did not block the response significantly, but instead displayed weak agonist properties The NMDA receptor antagonists AP5 (D-(−)-2-amino-5-phosphonovaleric acid) and CPP (3-(2-carboxypiperazin-4-yl)-propyl-1-phosphate), as well as NMDA itself, slightly inhibited the kainate responses, thus acting as weak antagonists without showing any agonist properties

Taken together, the electrophysiological properties observed in oocytes injected with GluR-K1 transcript, as well as the observed pharmacological properties, strongly indicate that GluR-K1 represents a functional kainate receptor indistinguishable from the one observed in oocytes injected with total poly(A)$^+$ RNA Thus, it appears that the single protein subunit encoded by GluR-K1 is sufficient to form an active receptor–ion-channel complex Whether this complex is composed of a single protein subunit *in vivo*, or whether it is a homo-oligomer assembled from several identical subunits, cannot be decided Given the fact that the depolarization induced by RNA *in vitro* transcripts of the isolated clone GluR-K1 is smaller than the one observed with forebrain poly(A)$^+$ RNA (Fig 1), it seems possible that additional receptor subunits exist that mig modify the channel properties The slight deviation of th Hill coefficient from unity suggests the presence of interactin multiple subunits

DNA and deduced amino-acid sequences

The cDNA insert of the plasmid pGluR-K1 was subcloned int M13mp19 and sequenced (Fig 3) An open reading frame 2,721 base pairs (bp) was found within the total length 2,992 bp Thus, the predicted protein consists of 889 amin acids, with a calculated M_r of 99,769 The deduced protei sequence contains a putative signal peptide of 18 amino aci at its N terminus, with a predicted cleavage site that confor to empirical rules[22] The N terminus of the protein therefore expected to be located extracellularly There are six possibl *N*-glycosylation sites present in the presumed extracellul domain Sequence comparisons with other ligand-gated io channels, the nicotinic acetylcholine receptors, GABA$_A$ rece tors and the glycine receptor, reveal little overall homology an much less than anticipated in the light of the recently propose 'superfamily' hypothesis[23,24] of ligand-gated ion channels I fact, using the sequence comparison algorithm of Feng, Johnso and Doolittle[25], no significant over-all homology is detecte between the protein encoded by GluR-K1 and the neuron neuronal nAChR subunits[26,27] $\alpha2, \alpha3, \alpha4, \beta2, \beta3$ or β GABA$_A$ receptor subunits[28] α or β, or the glycine recept subunit of M_r 48K[29]

All ligand-gated ion-channel subunits sequenced previousl have a conserved extracellular region characterized by two cy teine residues spaced 14 amino acids apart, with conserve proline and aspartate residues located 8 and 10 amino acid respectively, downstream from the first of these two cysteine This hypothetical signature for neurotransmitter recepto channel complexes[24] is conserved only poorly in the prote encoded by GluR-K1 Although the proline and aspartat residues are present, the first cysteine residue is located only residues upstream from the proline residue, and the secon cysteine residue is absent (Fig 5*a*)

A hydropathy plot analysis of GluR-K1 (Fig 4) reveals severa regions that are candidates for transmembrane domain (TMDs) The region between amino acids 455 and 810 is o particular interest as its hydropathy profile resembles that see in the other ligand-gated ion channels three closely space putative TMDs which are separated by ~175 amino-aci residues from a fourth putative TMD which is located close t the C terminus of the protein Although the presumed TMD I is very prominent, the assignment of three TMDs in the 'TMD cluster' region (amino acids 521-612) is less obvious Clearly, there are two very good candidate regions for TMDs, located at amino-acid residues 521-539 and 596-614, respectively A third TMD might be assigned to the region between amino-acid residues 463 and 480, or alternatively between residues 567 and 585 We favour the interpretation that the region between residues 463 and 480 actually represents a third TMD (see below) Thus, we would assign the following four transmembrane regions in GluR-K1 TMD I, located between amino-acid residues 463 and 480, TMD II between residues 521 and 539, TMD III between residues 596 and 614, and TMD IV between residues 788 and 808 The region between residues 463 and 480 is proposed as TMD I for two reasons First, in all ligand-gated ion channels the putative TMD I contains a conserved proline residue[23 24] which is located at position 12 in all nAChRs, and at position 8 in the GABA and glycine receptors In the putative TMD I of GluR-K1, a proline is found at position 12 Second, putative TMD II in GluR-K1 shows sequence homology with putative TMD II regions in the nAChRs (Fig 5*b*) Homology in this region might be expected in view of the fact that both nicotine-gated as well as glutamate-gated ion channels have to provide the environment for the passage of cations, and TMD II is the region that is thought to line the ion channel of the nAChR[30] Taken together, the structural features found in the GluR-K1 protein are consistent with this receptor being a member of the superfamily of ligand-gated ion channels The homologies detected, however, are not strong enough for an unequivocal conclusion to be reached, this will require the analysis of the primary structures of more members of the glutamate receptor family

Regional tissue distribution of GluR-K1 RNA

Northern blot analysis with the full-length GluR-K1 cDNA probe (Fig 6) revealed the presence of large amounts of a RNA species, 5 2 kb in size, in poly(A)$^+$ RNA isolated from cortex, cerebellum and hippocampus, and trace amounts of RNA in the brainstem Additionally, two minor bands corresponding to RNAs of sizes ~3 9 and ~3 2 kb were seen in these tissues These minor bands were also observed under conditions of high-stringency hybridization (see legend to Fig 6), ruling out the possibility of cross-hybridization to distantly related mRNAs Most probably, these minor bands represent GluR-K1 RNA transcripts emanating from different polyadenylation sites Control tissue from outside the CNS (liver and lung) showed no traces of GluR-K1 RNA, and neither did poly(A)$^-$ RNA from any of the tissues tested The regional distribution of GluR-K1 RNA in the brain correlates well with autoradiographic studies of kainate-binding sites, which showed the highest density to be in the hippocampus, with lesser density in cortex and cerebellum[7,31] and undetectable labelling in brainstem

Discussion

We have isolated a cDNA clone, GluR-K1, from a rat forebrain cDNA library by screening for expression of kainate-gated ion channels in *Xenopus* oocytes This cDNA encodes a functional glutamate receptor consisting of a single protein of calculated M_r 99,769, disregarding any possible post-translational modifications This protein forms an ion channel which possesses electrophysiological and pharmacological properties consistent with those reported for kainate receptors studied in more complex systems[16,18] or cultured neurons[32] The size of

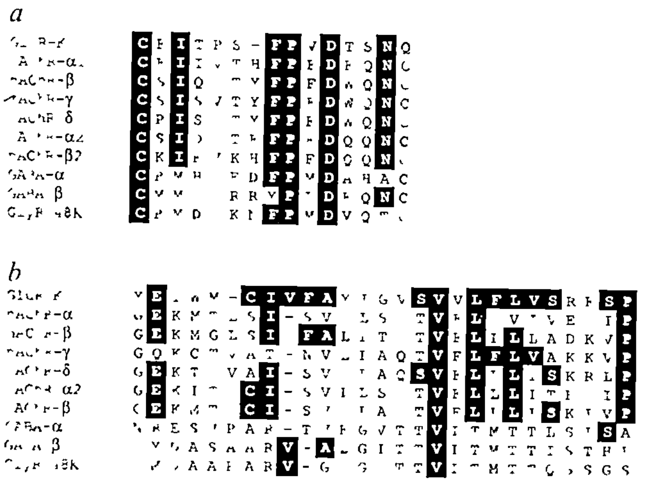

FIG 5 *a*, Comparison of the extracellular region located between amino-acid residues 89 and 106 of GluR-K1 with the 'Cys-Cys-loop' region found in all other ligand-gated ion channels, showing sequence homology Sequences of nAChR subunits α, $\beta 1$, γ, δ are from mouse muscle[46], those of nAChR subunits $\alpha 2$ and $\beta 2$ are from rat brain[26] GABA$_A$ subunits α and β are from calf brain[24] GlyR 48K is the 48K subunit of the glycine receptor from rat brain[29] Boxed amino acid residues are found at identical positions in GluR-K1 as well as in at least one of the other receptor sequences One gap has been introduced arbitrarily *b*, Comparison of the putative TMD II region of Glu-R-K1 with hypothetical TMD II regions of other ligand-gated ion channels[24,26 29 46] (as *a*), suggesting protein-sequence conservation

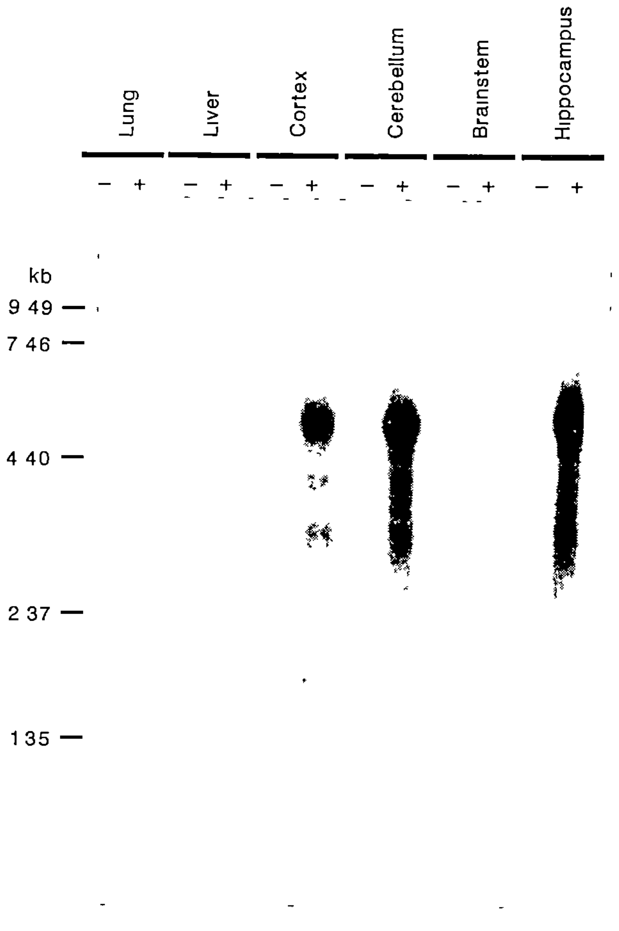

FIG 6 Northern blot analysis of six rat tissues for the presence of GluR-K1 message Poly(A)$^+$ RNA (3 μg per lane) and poly(A)$^-$ RNA (6 μg per lane) were prepared as in Fig 1, separated on 1% formaldehyde-agarose gels and transferred to a Nytran filter A full-length GluR-K1 DNA probe was prepared by the random prime method using the Amersham Multiprime DNA labelling kit and was hybridized (10^6 c p m ml^{-1}) to the filters Prehybridization and hybridization were at 42 °C in 4x SSC/40% formamide, and filters were washed in 0 2×SSC/0 1% SDS at 55 °C, followed by 0 1× SSC/0 1% SDS at 65 °C The RNA ladder from BRL was used to standardize RNA sizes + and − Poly(A)$^+$ RNA and poly(A)$^-$ RNA, respectively

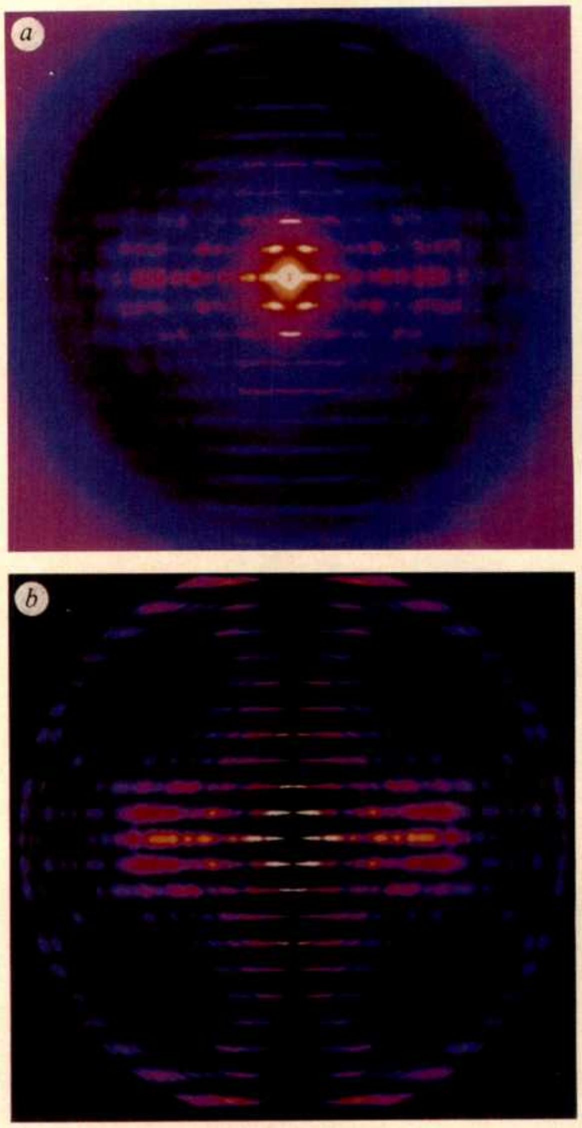

FIG. 1 X-ray diffraction pattern from reconstituted L-type straight flagellar filaments. *a*, Observed diffraction pattern. Straight-type flagellar filaments were isolated from *S. typhimurium* strain SJW1660 (provided by Dr R. Kamiya, Nagoya University) as previously described[24]. The filaments were depolymerized into monomers and were purified by fast protein liquid chromatography (FPLC) on a Mono-Q column (Pharmacia). The monomers were repolymerized into the filaments with the desired length distribution by adding 1 M ammonium sulphate to a flagellin solution (10 mg protein ml^{-1}). The reconstituted filaments were washed in 0.2 M glycine–NaOH, pH8, and were centrifuged for 20 h at 10,000*g*. The resulting soft pellet was transferred into a capillary tube. The filaments were orientated by being forced to flow back and forth in the capillary for 15 min to 2 h. The protein concentration of the specimen was 100–150 mg ml^{-1}. We used reconstituted filaments because native filaments are ~10 μm long and therefore the resulting pellet is too hard to orientate. The filaments were reconstituted from flagellin monomers so that the length distribution could be controlled. Well-oriented specimens were obtained with filaments of an average length of ~0.5 μm. Specimen preparation will be described in more detail elsewhere (I.Y., F.V. T. Noguchi and K.N., manuscript in preparation). Fibre diffraction experiments were done with a RIGAKU RU200 rotating anode X-ray generator using a 0.1-mm focal cup, operated at 40 kV and 25 mA and double mirror optics. CuKα-radiation (λ = 1.5418 Å) was used. The diffraction patterns were recorded on a photostimulable phosphor-plate (Imaging Plate, Fuji Film) with a 20-h exposure and a specimen-to-film distance of 170 mm. Recorded images were scanned with a Fuji Film BA100 Imaging Plate scanner using 0.1 mm rasters and were displayed on a Seiko D-SCAN GR4416 graphics terminal. Photographic copies were made with a Dunn Instruments MultiColor type 638 colour hardcopy camera. The much higher sensitivity and wider dynamic range of the Imaging Plate compared with those of photographic films[33] made the search for well-oriented specimens efficient and made it possible to record diffraction patterns with high signal-to-noise ratios in a relatively short time. *b*, Simulated diffraction pattern. The layer-line intensities were extracted from the diffraction pattern shown in *a* with the angular deconvolution method[25,26] and the diffraction pattern was reconstructed using these intensities and the angular spread function without background.

image reconstructions from electron micrographs have shown the subunit shape on the surface of the filament[12,13]. It has not yet been possible, however, to visualize the subunit packing in the filament to explore the architecture of this assembly. Also, flagellar growth *in vivo* is known to occur at the distal end of the filament[14,15], where the HAP2 protein forms a cap structure, which presumably serves to prevent arriving flagellin subunits from diffusing away before polymerizing[16,17]. It is thought that the flagellin molecules are transported through the central channel of the filament, but the channel structure has not yet been unambiguously determined.

The helical form of the wild-type filament is postulated to involve two different conformations of flagellin monomers in one filament[5,18–21]. The structural symmetry, therefore, is complicated and analysis of wild-type filaments is not feasible. Straight filaments, in which all subunits are in the same conformation, would make structural analysis possible. Such filaments have been isolated from mutants of *S. typhimurium*[22,23].

We have solved the structure of a straight-type mutant bacterial flagellum at a resolution of 20 Å, using X-ray fibre diffraction. The electron density map clearly shows the shape of the whole subunit as well as the packing and indicates that the innermost domain of each subunit is mostly responsible for filament formation. The map also shows the central channel of the filament, which is large enough for folded flagellin monomers to pass through. Based on other evidence, we have made tentative assignments of primary sequence to the morphological domains observed. In particular, because a proteolytic fragment of flagellin missing portions of the terminal regions cannot polymerize into the filament[24], the innermost domain was assigned to the amino- and carboxy-terminal segments. The intensity distribution at 10-Å resolution in the diffraction pattern indicates that the innermost domain, which forms the core of the filament, consists of a bundle of α-helices aligned in parallel to the filament axis.

X-ray fibre diffraction

There are two types of straight filament (L- and R-type), whose subunits are assembled with opposite-handed helical symmetry. Figure 1*a* shows a fibre diffraction pattern from reconstituted L-type straight filaments from *S. typhimurium* strain SJW1660. Flagellin from this strain differs from that of the wild-type strain SJW1103 by only one amino acid (S. Kanto and S.-I. Aizawa, personal communication). Because the diffraction pattern shows very little interference from lateral lattice formation, it is equivalent to the cylindrically averaged diffraction pattern from a single filament. The helical symmetry is reasonably well approximated by 331 subunits in 60 turns of the basic helix. The pitch of the basic helix is 26.35 Å, as measured from layer lines 2, 4 and 6, where the Bessel orders 1, 2 and 3 contribute, respectively. The axial rise per subunit is 4.78 Å, as measured from layer line 11, where the Bessel order 0 contributes. The structure repeats every 1,581 Å along the filament. Layer lines indexed by 1,581 Å spacing are not individually visible because

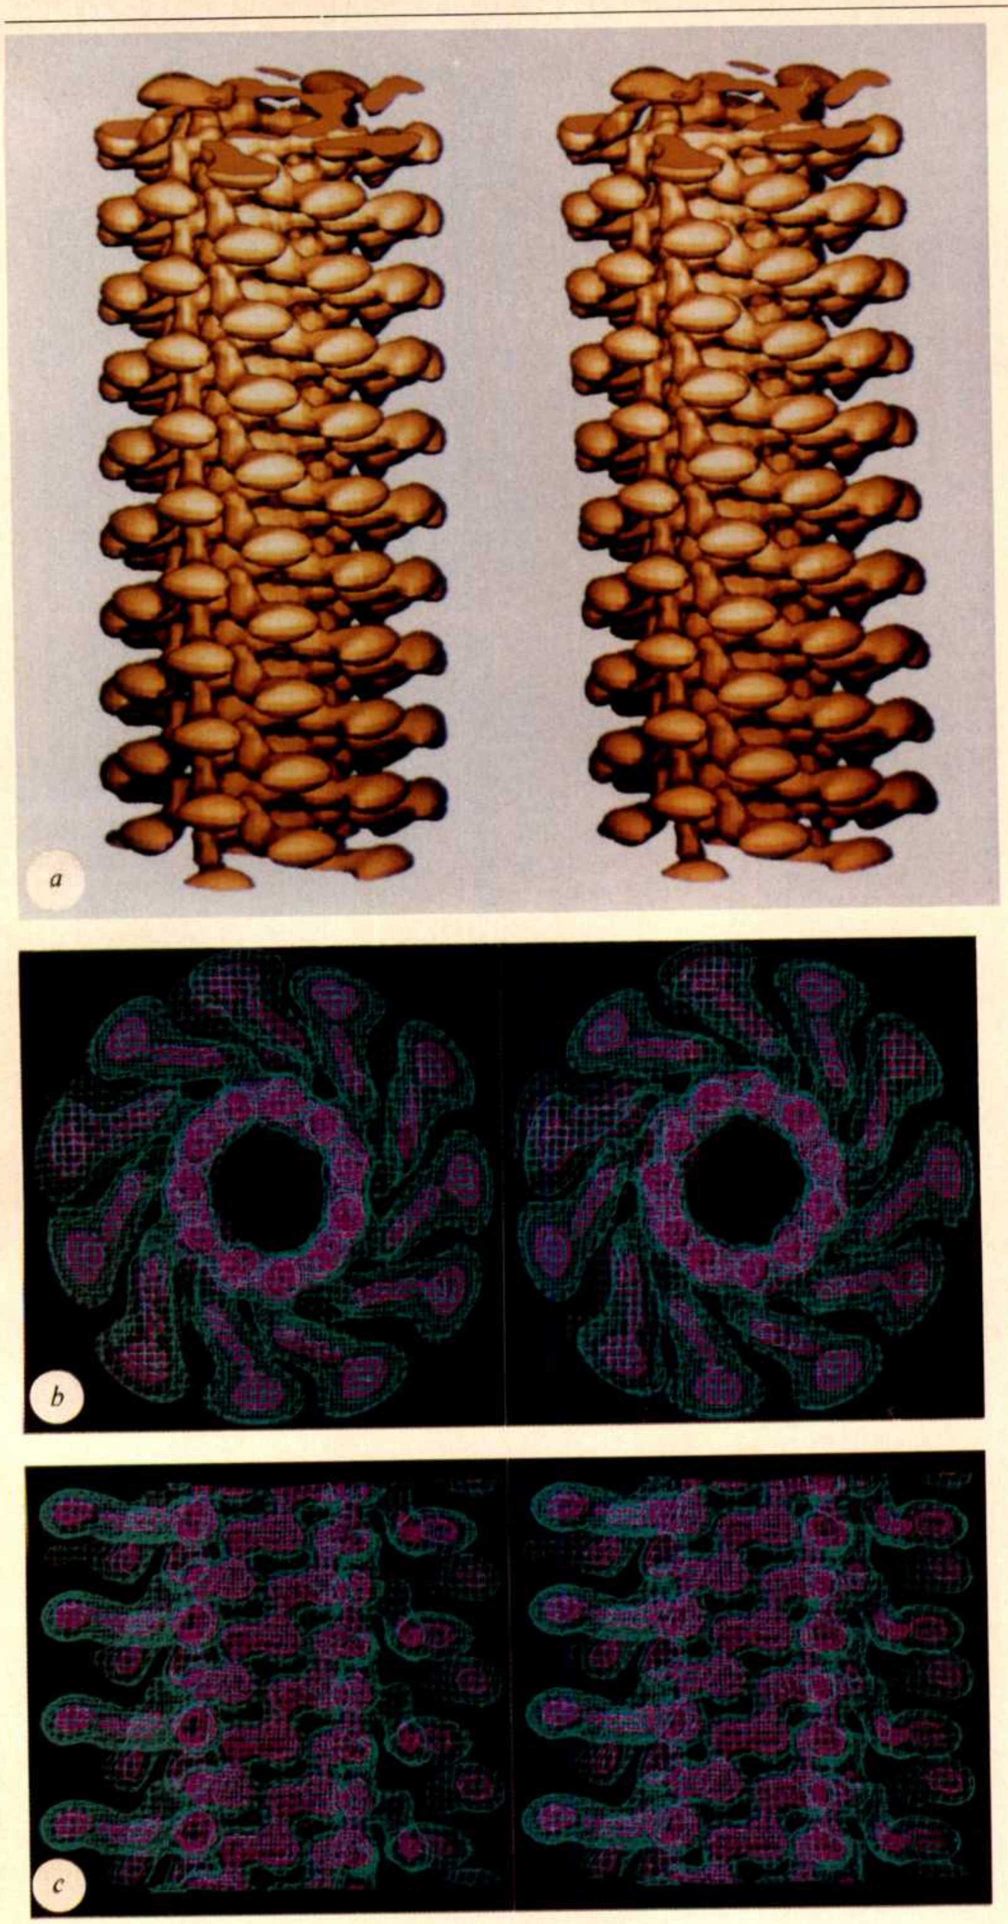

FIG. 5 Refined electron density maps. *a*, Oblique view of a shaded solid representation of the contoured map. The map is contoured at level 30, which gives ~80% of the correct volume. The length of the map along filament axis is 500 Å. *b*, Cross-section of the filament with 52.5 Å axial thickness. *c*, Longitudinal section. The section is 55 Å thick and 200 Å long axially. The position of this section is indicated on the left side of *a*. The maps in *b* and *c* are both contoured at two levels of 30 and 90.

Figure 5*c* is a longitudinal section of the filament viewed from inside, being 55-Å thick and 200-Å long along the axis; the region comprising this section is indicated on the left side of Fig. 5*b*. Axial stagger of the subunits is visible in the middle of the section shown in Fig. 5*c*. Neighbouring subunit relations are along the 5-start left-handed helix to the top right, along the 6-start right-handed helix to the top left, and along the basic helix nearly horizontally as indicated in Fig. 2*a*. The domain contacts are so close in the core that it is hard to distinguish from the lower contour whether the vertical rod density lying along the 11-start helix or the horizontal density along the basic helix belongs to a single subunit. From the higher contour the latter is more likely to belong to a single subunit. Then, the subunit contacts are extensive along the basic and the 5-start helices, and less extensive along the 6-start helix.

A subunit can be divided into three domains, which are labelled in Fig. 6*a*. Measuring along the filament radius, domains 1, 2 and 3 extend from 30–55 Å, 55–80 Å and 80–120 Å, respectively. The innermost domain (domain 1) has the highest density and is responsible for most of the filament formation. The middle domain (domain 2) seems to have some interaction with domain 3 of the neighbouring subunit in the clockwise direction, but this interaction is not as close as that between domains 1 of neighbouring subunits. Domain 3 is on the filament surface and is presumed to determine the antigenic properties. Domain 1 seems to consist of two globular subdomains, only one of which is extensively connected with domain 2 within a subunit. Domain 2 is a vertical rod of 35-Å length, slightly tilted towards the filament axis. Domain 3 appears somewhat fin-shaped, 50 Å long and 50 Å wide at its widest part with an axial thickness of ~25 Å.

Assignment of amino-acid sequence

The volume of each domain was estimated from the refined map and the corresponding molecular weights are listed in Table 1. The distribution of α-helical secondary structure in flagellin was predicted from the primary sequence and is plotted in Fig. 6*b*, with the domain boundary positions determined by proteolytic digestion[24]. F40 and F27 represent fragments with M_rs of 40K and 25K, respectively, which were isolated from a digestion mixture. The predicted secondary structure is consistent with circular dichroic spectra of flagellin and its fragments in the far ultraviolet region (F. V., H. Uedaira, S. Kidokoro and K.N., manuscript in preparation). It has also been shown that the terminal regions of monomeric flagellin are partially unfolded and flexible[24].

Because the terminal regions of flagellins of different serotype or even from different species have high amino-acid homology, these terminal regions are believed to be important in filament formation[4,29,30]. Indeed, the F40 fragment, which is missing the 65 N-terminal residues and 44 C-terminal residues of flagellin, cannot form filaments even under conditions that favour polymerization[24]. It is reasonable, therefore, to assign these terminal regions to domain 1, the estimated volume of which is consistent with such an assignment. As the F27 fragment contains the region of highly variable sequence responsible for flagellar antigenicity[31], it probably corresponds to domain 3 located on the filament surface; the estimated volume of domain 3 is consistent with this. Domain 2 can, therefore, be assigned to the parts of F40 absent from F27 on the basis of both deduction and estimated volume. These assignments are summarized in Fig. 6. A part of D2 indicated in Fig. 6*b* could, however, be contributing to the filament core, because the amino-acid replacements which

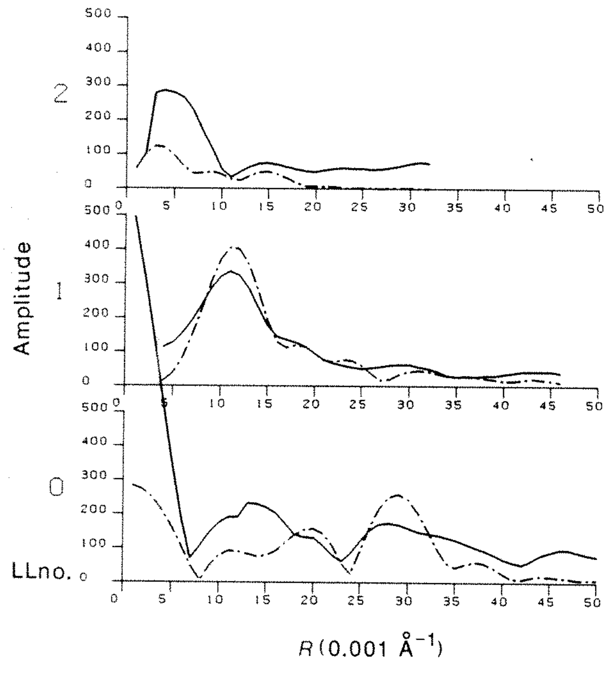

FIG. 3 A comparison of layer-line amplitudes. Solid line, X-ray fibre diffraction data; dashed line, data used in three-dimensional image reconstruction from electron micrographs[13]. The data represented by the dashed line were calculated by grouping layer-line intensities from the original data[13] according to the *n,l* plot in Fig. 2*b*. It was not possible to obtain the data for the peak at the origin of layer line 0 from the X-ray diffraction pattern because of the interfilament-interference effect observed here. Therefore, the data from the image reconstruction work[13] were scaled-up three times so that the initially negative radial density distribution at the filament axis became zero. Adjusting the negative density level to zero improves the molecular envelope, resulting in the better-refined images. LL no., Layer-line number.

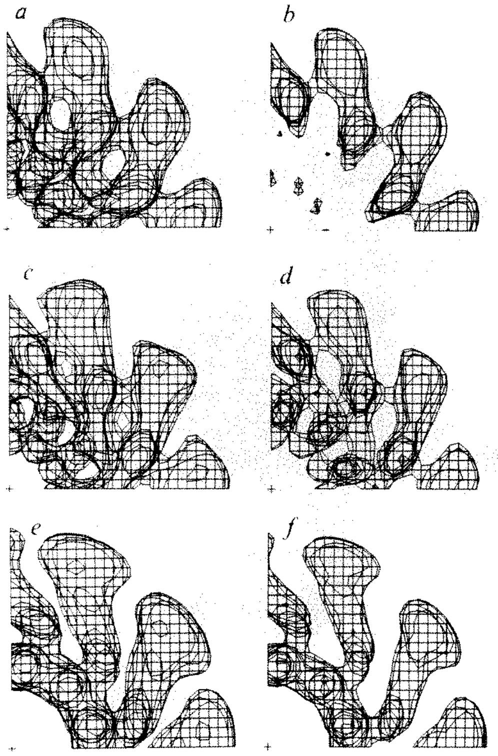

FIG. 4 Improvement of the electron density maps during the phase refinement procedure. Only a quarter of a cross-section of the filament is shown for each map. The sections are 52.5 Å thick. *a*, *b*, Three-dimensional image reconstruction from electron micrographs of frozen hydrated specimens[13]. *c*, *d*, Maps calculated with the amplitudes from the X-ray diffraction pattern and the phases from the three-dimensional image reconstruction. *e*, *f*, Maps calculated after 10 cycles of the solvent-flattening phase refinement procedure. The maps are contoured at density level 30 in *a*, *c* and *e*, and 50 in *b*, *d* and *f*, where the highest density is ~150 in arbitrary units.

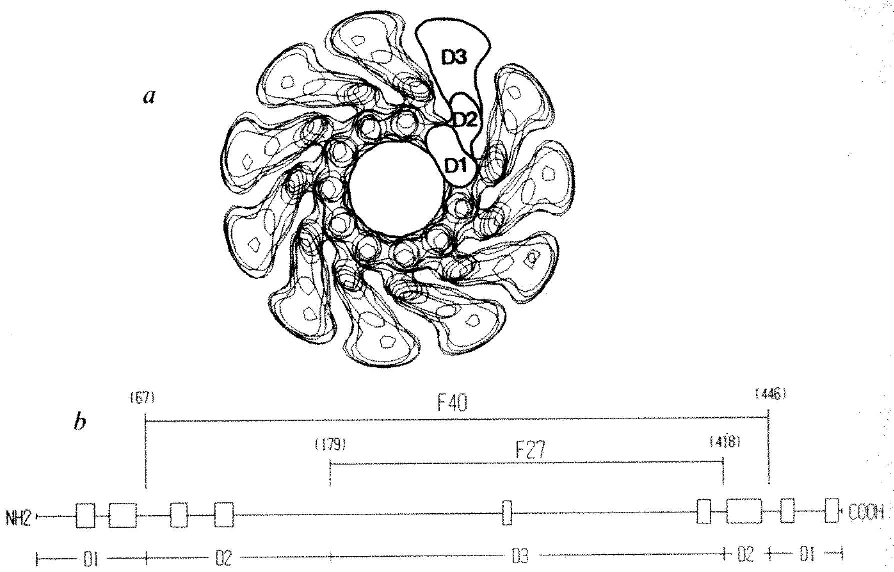

FIG. 6 Amino-acid sequence assignment for domains in the electron density map. *a*, Contoured electron density map viewed along the filament axis. Twelve sections at 4.7-Å intervals are superimposed and the domains are labelled. *b*, Diagram showing the predicted distribution of α-helices and the domain boundary positions. Rectangles represent α-helices. The secondary structure was predicted using the program ALB[35] obtained from Brookhaven Protein Data Bank. The domain boundary positions were determined by proteolytic digestion[24].

affect filament shape are in the D2 region and the interspecific sequence homology of this region is as high as that of D1[4,29,30]. Thus, the sequences with high α-helical content are assigned to domain 1 and 2 and the non-α-helical part to domain 3; this is consistent with the interpretation of the intensity distribution at ~10-Å resolution in the diffraction pattern. Preliminary model fitting shows that the cross-section of domain 1 shown in Fig. 6*a* is just the right size to consist of two bundles, each containing four α-helices, arranged side by side with their axes parallel to the filament axis. Differential scanning calorimetry of F27 suggests that domain 3 contains two thermodynamically independent units (F.V., H. Uedaira, S. Kidokoro and K.N., manuscript in preparation), although it is not visible in the map at the present resolution.

Central channel

Although it is known that the growth of flagellar filaments *in vivo* occurs at the distal end[14,15], it is not known how flagellin monomers reach the tip of the filament. Although the best explanation is that flagellin monomers pass through the filament's central channel, there has not been any experimental evidence showing that the central hole is large enough to accomodate folded flagellin molecules. Unlike tobacco mosaic virus[32], electron micrographs of negatively stained filaments do not show the hollow channel, for reasons that are unknown. Three-dimensional image reconstructions from electron micrographs[13] show a small hole (Fig. 4*a*), which could suggest that flagellin monomers are transported in an unfolded and stretched conformation. But the density distribution of the core-part forming the hole was weak and noisy. The refined electron density map using X-ray fibre diffraction data shows well-defined subunit packing in the core region and a central hole of ~60-Å diameter, which is large enough to accommodate the folded flagellin molecule with the elongated shape shown in Fig. 6*a*. It is probable, therefore, that flagellin molecules are transported through the central channel with the same conformation as they have in solution. A hole of this size should be visible by electron microscopy. Electron micrographs of transverse thin sections of reconstituted filaments show a large central hole, supporting the result described above, whereas native filaments have a filled appearance, indicating that the central hole of native filaments is filled with flagellin molecules (T. Akiba, C. J. Jones and K.N., manuscript in preparation).

Implications for flagellar function

Having made the correspondence, shown in Fig. 6, between the volumes of the domains that appear as distinct entities in Fig. 5 and fragments of flagellin defined in biochemical assays, it is easy to understand how each domain of the flagellin subunit can be independently responsible for its respective role. Antigenicity is an important function of the highly variable domain 3; this variability can leave the filament structure undisturbed, because domain 1 alone seems to be able to form the filament backbone regardless of the conformation of domain 3, provided it is not oversized. If the boundary of domain 1 shown in Fig. 6*a* is correct, subunit addition during polymerization proceeds along the basic helix at the bottom of the filament shown in Fig. 5*a*, where only one site would be available for subunit addition at a time. About 100 residues at the terminal regions of flagellin, which are in a flexible conformation in solution (ref. 24; and S.-I. Aizawa, F.V., R. Ishima and K. Akasaka, manuscript in preparation), become well folded in an α-helical conformation when bound to the end of the basic helix. Because it is difficult to conceive how these terminal regions could be recognized by the binding site if they were totally unfolded, they must be in a somewhat folded conformation. In agreement with this, circular dichroic spectra indicate the presence of some unstable α-helical structure in these regions of monomeric flagellin[24].

The model proposed for flagellar polymorphism[5,18-21] assumes high cooperativity within a protofilament running along an 11-start helix, and independence between protofilaments. The structure presented here does not directly support this model, because one of the two subunit-contacts along a protofilament is relatively weak and a subunit extends over two protofilaments. But the structure presented here is not inconsistent with the model either, because high cooperativity does not necessarily require a direct connection along the protofilament, and a protofilament consisting of two subdomains of domain 1, each coming from neighbouring subunits, could be independent from neighbouring protofilaments, to which the other subdomains of domain 1 contribute, if subdomains behave as independent subunits. In fact the present structure, in which a subunit appears to extend over two protofilaments, seems to correspond to the scheme proposed by Calladine[19,20]. Because the resolution of the structure at present is not high enough to permit the confident description of the subunit connections, further attempts to reconcile it with the current model of polymorphism are premature. Comparison of this structure with that of R-type straight filament should help resolve this question. ☐

If the upstream flow speed becomes relativistic ($V_1 \leq c$), anisotropies in the particle distribution at the shock invalidate the diffusion approach (see Fig. 1). Numerical simulation, on the other hand, shows that $\Delta p/p \gg 1$, with a resulting enhancement in the acceleration rate.

For $V_1 = 0.96c$, $V_2 = 0.32c$ (that is, for a relativistic compression ratio r of 3, see ref. 7), Fig. 2 shows the frequency distribution of $\Delta p/p$, which averages at ≈ 10.5. The large resultant fractional energy increase is, on average, approximately γ^2, where $\gamma = (1 - V^2/c^2)^{-1/2}$, and V is the relativistic difference between V_1 and V_2. The average relativistic cycle time t_r, for a given initial momentum p_i, is also provided by the model. Typically, within a time t_r, a cosmic-ray particle in the shock vicinity crosses it twice, and is accelerated from momentum p_i to momentum $p_f = (1 + \Delta p/p)p_i \approx 11.5p_i$. To compare the relativistic result with diffusion theory, the nonrelativistic acceleration time, t_{nr} given by equation (2), is calculated using identical values of p_i, p_f, V and λ/p. It is found that $t_{nr}/t_r \approx 13.5$.

Figure 3 shows how an escape probability per cycle P can be deduced from a frequency histogram giving the number of cycles before escape. Because neither this, nor $\Delta p/p$ are small compared with unity, the particle number power-law index of $-1 - (P/(\Delta p/p))$ does not develop in the initial few decades of energy beyond the injection energy.

Relativistic shocks have been studied by Bogdan and Webb[8], and by Kirk and Schneider[9]. The former used a two-stream approximation, wherein particle velocity directions are reversed in each scattering. Their results are more dramatic than ours. The latter, on the other hand, used pitch-angle diffusion with a small mean scattering angle, and reported considerably milder acceleration. Owing to the breakdown of diffusion theory in relativistic shocks, a sequence of many small-angle scatterers can no longer be replaced by a few large-angle scatterers with longer mean free path. Because our results correspond to isotropic scattering, they fall somewhere in between those of these two previous works.

To support our use of isotropic scattering centres, we develop an argument based on scaling known properties of energetic-particle scattering in the interplanetary medium. Cosmic-ray modulation studies indicate that $\lambda \propto L_m$ (magnetic rigidity) in the relativistic regime[10]. Detailed trajectory integration in a field model based on the region around an interplanetary shock reveal large pitch-angle changes ($\Delta \cos\theta \sim 0.5$–$1$) occurring in times that are short compared with the travel time between these events (see Figs 2a, b, c of ref. 11). The mean free path λ derived for this particular data set can be fitted by $\lambda = K\rho_c$ for a particle cyclotron radius ρ_c with the empirical constant $K = 41$ (ref. 12). For $L_m = 200$ MV we have $\lambda = 0.03$ AU which is roughly the separation seen between the large-amplitude waves existing behind the shock wave we are studying (see Figs 1a, b of ref. 13). Quasilinear scattering theory, based on a series of small pitch-angle changes, certainly does not apply in the disturbed ($\Delta B/B \approx 0.3$) interplanetary field[10], and we suggest that such knowledge as we have of AGN jets and shocks indicates a similar regime.

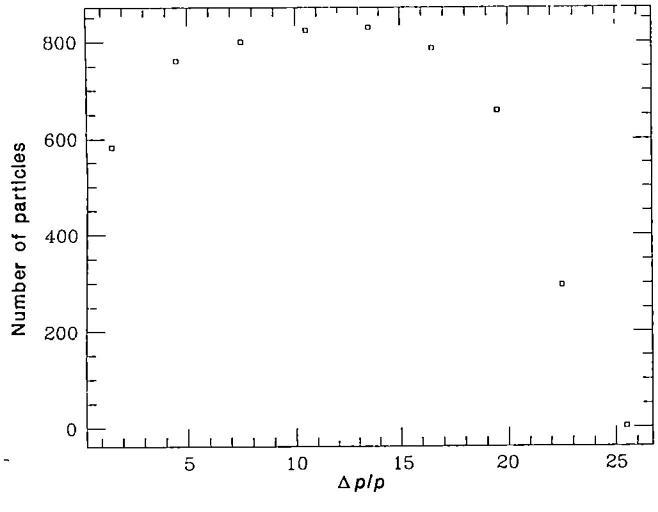

FIG. 2 Frequency distribution of $\Delta p/p$, the fractional change of cosmic-ray momentum within a cycle of downstream–upstream–downstream traversals, for a parallel relativistic shock with $V_1 = 0.96c$, $V_2 = 0.32c$.

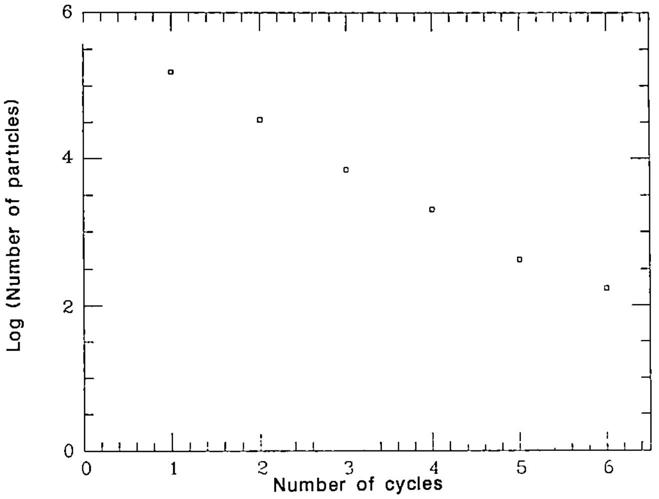

FIG. 3 Frequency distribution of n, the number of downstream–upstream–downstream cycles that a cosmic-ray particle makes before it leaves the shock, for a parallel shock with $V_1 = 0.96c$, $V_2 = 0.32c$. Note that the frequency is proportional to $(1 - \alpha)^n$, where α is the escape probability per cycle. As the frequency is given on a logarithmic scale, the plot yields an approximate straight line of slope $-\alpha$.

Magnetic fields in AGN hotspots, the shock working surface of our model, are $\sim 4 \times 10^{-4}$ G. Hence for large-angle scattering of particles with momentum 10^{16}–10^{19} eV/c (where c is the speed of light) we need structures separated by corresponding λ-values that are 1 pc–1 kpc. But large-scale inhomogeneities in synchrotron emission are seen[14] in the jet of 3C120, for example, on scales of ~ 10 mas–10 arcsec, corresponding approximately to these λ-values. Whether these structures are individual small-scale shocks or instabilities or other nonlinear wave effects, they must all feed equivalent-scale inhomogeneities into the hotspot shock at the jet termination.

Although observation of relativistic jet speeds is only convincing near the core and according to some calculations there is a significant slowing before the hotspot, the data are still consistent with maintenance of relativistic speeds throughout[14], and one theory involves re-acceleration of a plasma[15]. Observation of one-sided jet sources reveal more depolarization on the opposite (non-jet) side[16]. This depolarization is continuous in angular dependence and, in one case at least, arises from a foreground effect. Doppler beaming as a reason for one-sidedness and relativistic flow on all length scales are likely explanations[17]. Other parameters for the shock working surface are taken from Laing[18] who found field strengths of $\sim 4 \times 10^{-4}$ G at the hotspot and dimensions of this region of ~ 20 kpc from a survey of AGN jets. The field tended to be parallel to the jet, before and within the hot spot, suggesting a parallel-shock model.

For particles of rigidity 10^{19} V accelerated by a planar parallel shock, $V_1 = 0.96c$, $V_2 = 0.32c$, $\lambda = 41\rho_c$ with a 4×10^{-4} G mean field, the equation (2) acceleration time constant, enhanced by the calculated factor of 13.5 is $\approx 2 \times 10^4$ yr. This is short compared with the proton synchrotron and 2.7-K photoionization loss times of 9×10^7 yr and 10^{10} yr respectively. The diffusive loss time, T_d from the medium over a distance R of 10 kpc is 2×10^5 yr according to $T_d \approx 3R^2/4\lambda c$, which is still longer than the acceleration time At 10^{20} V, however, $\lambda = 10$ kpc according to our model, so diffusive acceleration is not likely at this rigidity Iron nuclei at rigidities $<10^{19}$ V, however, can supply the energy for the 10^{19}–10^{20}-eV particles

Following Ginzburg[19,20], the origin of 10^{17}–10^{20}-eV cosmic rays is due to acceleration within the local supercluster (~30 Mpc in size) in which conservatively ten AGNs may be described by the parameters adopted here An individual AGN power output of $2.6\times10^{51}/T$ erg s^{-1} is required to explain the observed $>10^{17}$-eV spectrum for a loss time T in the supercluster Taking an intercluster field of 10^{-8} G yields a diffusive loss time of 2×10^9 yr at 10^{17} eV, and nuclear collision and photoionization losses are negligible The required jet power into $>10^{17}$-eV particles of 5×10^{34} erg s^{-1} is small compared to that seen in the radiofrequency range ($\leq10^{46}$ erg s^{-1}) and even if the accelerated, low-energy cosmic-ray gas significantly loads the jet because of wave-particle interaction, the high end of the spectrum can still be treated by the test-particle approach

The actual spectrum of $>10^{17}$-eV cosmic-ray protons expected for our galaxy on the basis of the above model depends on the source spectrum, the momentum-dependent diffusion in the supercluster and the spectrum of source sizes For a single source at the centre of a homogeneous diffusing medium with a free-escape boundary at R and a catastrophic particle-loss time constant T_e, the propagation equation

$$\frac{\lambda c}{3}\nabla^2 n(p,r) - \frac{n}{T_e} = -Q\delta(r) \qquad (3)$$

has as a leading term in the $r \ll R$ solution, $n \propto \lambda^{-1}$ (ref 19) Here, Q is the source function, r is the distance from the centre of the diffusing medium and $\delta(r)$ is the Dirac function Thus the dominance of diffusive loss in the supercluster is expected to steepen the calculated differential-source spectrum, which has a p^{-1} dependence, by one power of p, because $\lambda \propto p$ If, in addition, the upper cutoff rigidity of each of the AGN hotspot contributions increases with available jet energy, there is a further spectral steepening The 10^{17}–10^{20}-eV cosmic-ray spectrum is believed to be $n \propto p^{-3}$, although a heavy-nuclei origin of the highest-energy air showers would require a further steepening Some contribution to the overall spectrum below the knee in the primary cosmic-ray spectrum is expected, but this is not important if the escape probability from the galaxy reduces to a $p^{-0.5}$ dependence and the energetic-particle loading of the accelerator eventually sets in We note that, experimentally, this feature may extend as low as 10^{13} eV ☐

WHETHER or not neutron-star magnetic fields decay is a matter of current debate The recent observation[1,2] of cyclotron lines from γ-ray-burst sources, thought to be relatively old neutron stars, indicates that they are strongly magnetized and therefore that their fields have not decayed One interpretation of the correlation observed[3] between the strength of the magnetic field and the mass accreted by the neutron star is that mass accretion may itself lead to the decay of the magnetic field. Adopting the hypothesis of accretion-induced field decay, we calculate here the consequent evolution of a neutron star's spin and magnetic field The results are consistent with observations of binary and millisecond radio pulsars. Thermomagnetic effects[4] could provide a possible physical mechanism for such accretion-induced field decay.

Statistical analyses[5,6] of ~400 radio pulsars and the study[3] of the origin and evolution of magnetized neutron stars in binary systems are consistent with the assumption that neutron stars are born with magnetic fields of 10^{12} G which then decay with a time constant of $5-10\times10^6$ yr Estimates of age and magnetic field strength of binary millisecond radio pulsars, however, require[7] that the field decay, if it occurs, should stop or proceed much more slowly on timescales of $\geq10^9$ yr, at field strengths $\leq10^{10}$ G Pulsar models in which magnetic fields do not decay but align with the rotation axis are shown to also be consistent with the observed properties of radio pulsars[8-10]

Ohmic dissipation of electrical currents in the crust has been thought to be the physical cause for field decay[11] Recent calculations[12] of the ohmic decay of dipolar magnetic fields, however, have shown that the field does not decay exponentially as has been assumed in most statistical analyses of radio pulsars and that, if the field occupies the entire crust, it decays by less than a factor of 100 in a Hubble time

If the strong magnetic fields of neutron stars do not decay, then the origin of the weak magnetic fields of less than 10^{10} G, found in binary and millisecond radio pulsars[13], remains to be explained Neutron stars in binary and millisecond radio pulsars are thought to be formed by the iron-core collapse of massive stars or by the accretion-induced collapse of massive white dwarfs (for reviews see refs 14, 15) In one model for the weak field and rapid rotation of millisecond radio pulsars it is argued that it is simply white dwarfs[16-18] or iron cores of massive stars[19] having the appropriate field strength and angular momentum that give birth to the observed millisecond radio pulsars after a collapse In another model, mass accretion in low-mass X-ray binaries, which are assumed to be progenitors of millisecond radio pulsars, is proposed to cause both the field decay[20] and the spin-up[21] In fact, Taam and van den Heuvel[3] found a possible inverse correlation between the magnetic field strength and the estimated total mass of accreted matter for binary X-ray sources and for binary and millisecond radio pulsars This inverse correlation supports the latter model A study of the evolution of magnetic fields in the crust of a neutron star[4] showed further that the inward heat flux caused by mass accretion gives rise to thermomagnetic effects that could remove the strong magnetic field of a neutron star Here we examine further the possibility that magnetic fields of neutron stars decay only when neutron stars undergo mass accretion by considering γ-ray bursts and the periods and field strengths of binary and millisecond radio pulsars

The recent discovery[1 2] of cyclotron absorption lines with 20-keV and 40-keV energies in γ-ray bursts revealed that the central objects of γ-ray bursters are, as indicated in some theoretical works[22,23], strongly magnetized neutron stars with magnetic fields of 10^{12} G The statistical arguments indicate $\sim 10^7$ yr (refs 24, 25) or $\gg 10^7$ yr (ref 26) for the age of neutron stars in γ-ray bursters depending on the assumed distance When combined with the high field strength, the latter age estimate contradicts the field-decay hypothesis whereas the former does not

We note that the absorption lines were seen only in a limited portion of the burst[1] This can also be used to test the field-decay hypothesis because the presence of the cyclotron lines may depend sensitively on the configuration of the magnetic field relative to the line of sight[27] If this is the case, the 5-10-s duration of the cyclotron-absorption feature indicates the rotation period of $\geq$10-20 s This rotation period and the field strength put the γ-ray burst sources into the category of the 'turned-off' pulsars[6] If the spin-down of the neutron star is caused by the magnetic field, which decays exponentially on a timescale of τ_B, the variation of the rotation period P with time t is represented by $P^2 = AB_0^2\tau_B[1-\exp(-2t/\tau_B)]+P_0^2$ where B_0 and P_0 are initial field strength and rotation period, respectively, and the constant A is $9\ 8\times 10^{-40}$ s G^{-2} for a stellar moment of inertia of 10^{45} g cm^2 and radius of 10^6 cm To attain the rotation period of $\geq$10-20 s from the initial value of $\leq$1 s, magnetic braking requires the initial field strength of the neutron star to be larger than $\sim 2\times 10^{13}$ G if $\tau_B \sim 10^7$ yr This value of the initial field seems large, compared to the average values of $\sim 10^{12}$ G indicated by the statistical analyses of radio pulsars Therefore we pursue here the other possibility—that the magnetic fields of γ-ray burst sources, which might be isolated neutron stars, do not decay

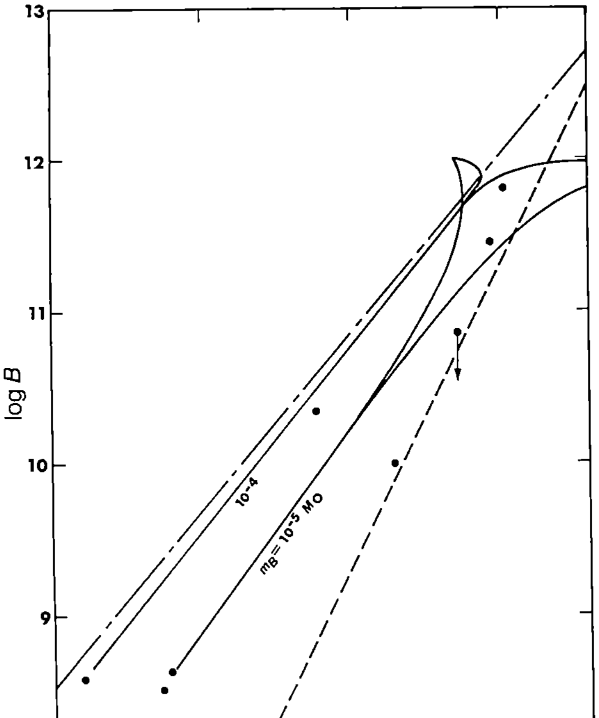

FIG 1 Evolutionary tracks (solid lines) of neutron stars in the plot of magnetic field as a function of rotation period Rotation periods and magnetic fields become smaller with accreted mass and hence with increasing time After mass accretion stops, the parameters develop horizontally to the right The initial magnetic field is taken as $B_0=10^{12}$ G, the initial rotation period is chosen as $P_0=0\ 5$ or 100 s, and the mass accretion rate is fixed at $M=1\ 1\times 10^{18}$ g s^{-1} The mass, radius and moment of inertia of the neutron star are taken as 1 4 $M_\odot$, 106 cm, and 10^{45} g cm^2, respectively The dash-dotted and dashed lines denote the equilibrium rotation[28] and pulsar-death lines[6], respectively The filled circles represent the positions of binary and millisecond radio pulsars in this diagram

As already mentioned, the weak magnetic fields of $\leq 10^{10}$ G are found in binary and millisecond radio pulsars[13], these magnetic fields are plotted against rotation periods in Fig 1 In the resurrected-pulsar model[21] the progenitors of millisecond radio pulsars are the low-mass X-ray binaries and their rapid rotations are the consequence of the spin-up that is due to the mass accretion in binary systems We consider the weak magnetic field and the rapid rotation of these radio pulsars in terms of the hypothesis that mass accretion leads to both spin-up and field decay We assume that the magnetic field decays with accretion as

$$B=\frac{B_0}{1+\Delta M/m_B}=\frac{B_0}{1+Mt/m_B} \qquad (1)$$

where B is the field strength at time t, ΔM the accreted mass, m_B the mass constant for the field decay and M the accretion rate Equation (1) fits well the inverse correlation between the magnetic field strength and the estimated mass of the total accreted matter for binary X-ray sources and binary and millisecond radio pulsars[3] As already noted[3], this inverse correlation is also consistent with the simple field-decay hypothesis if the larger amount of accreted matter is interpreted simply to reflect the greater age of the neutron star Although we do not advocate any physical model leading to equation (1), we do assume that a direct relation between field loss and accreted mass exists We note that equation (1) represents a change in the whole field, not just the component perpendicular to the rotation axis Using the formula given by Ghosh and Lamb[28] for the accretion torque, the variation of rotation period is described by $P = -0\ 11I^{-1}(GM)^{3/7}(BR^3)^{2/7}nM^{6/7}P^2$ where n is the dimensionless accretion torque (see ref 28), R the radius, I the moment of inertia and G the gravitational constant The calculated evolutionary tracks in the plot of the magnetic field against rotation period are shown by the solid lines in Fig 1 The rotation periods and magnetic fields decrease with time We ended our calculations when the inner edge of the accretion disk reached the surface of the neutron star When the mass constant for the field decay is $m_B \geq 10^{-3}M_\odot$, the evolution proceeds along the equilibrium rotation line[28] (dash-dotted line in Fig 1), where the spin-up torque that is due to accreting matter and the spin-down torque that is due to magnetic field are balanced This is because the timescale of the field decay is longer than the spin-up timescale After mass accretion stops, the parameters develop horizontally towards the right in Fig 1 If $m_B \geq 10^{-4} M_\odot$, the calculated evolutionary tracks are consistent with B and P of binary and millisecond radio pulsars These evolutionary tracks are also approximately consistent with the B and P of low-mass binary X-ray sources such as suggested from the beat-frequency model[29] for the quasiperiodic X-ray oscillations (see ref 30 for a review) Note that the possible inverse correlation[3] between B and ΔM is represented well by equation (1) with $m_B \sim 10^{-4} M_\odot$ Hence, if we adopt $m_B \sim 10^{-4} M_\odot$, the accretion-induced field-decay hypothesis represented by equation (1) is consistent with B, P and ΔM as observed or estimated for binary and millisecond radio pulsars and binary X-ray sources

The magnetic fields of single radio pulsars are in the range of 10^{11}-10^{13} G with a distribution peak around 10^{12} G The accreted mass of interstellar matter onto a single radio pulsar is negligible compared to $m_B \sim 10^{-4} M_\odot$ Hence, according to the accretion-induced field-decay hypothesis, the present field strengths of single radio pulsars should be equal to their initial values But this assertion conflicts with the results of the statistical analyses[5 6] of radio pulsars, which suggest that surface fields decay on a timescale of $5-10\times10^6$ yr Pulsar statistics depend, however, on the assumptions made for the radio luminosity law, the braking index, the magnetic-field evolution, the distribution of initial field strength and so on To resolve the above conflict, the statistical analysis under the assumption of no field decay should be conducted, examining especially the dependence on the assumptions for the above properties

Mass accretion of neutron stars is likely to give rise to the inward heat flow through the crust The thermomagnetic effects in the crust that arise from this inward heat flux, such a suggested in ref 4, have been invoked as a possible mechanis of the accretion-induced field decay The formula of ref predicts, in its simplest form, a stronger dependence of the fiel decay on time than does equation (1) The field-decay formul based on thermomagnetic effects, however, may depend on th structure of the crust, the accretion process and the histor of the heat flux A more detailed study of the thermomagnetic effects in the crust is needed to resolve the controversia issue of the field decay in neutron stars Other possible mechanisms for the accretion-induced field decay should also b explored □

A hierarchy of catastrophes as a succession of stability limits for the crystalline state

J. L. Tallon

Interdisciplinary Research Centre in Superconductivity, Madingley Road, Cambridge CB3 0HE, UK

MANY theories of melting have focused on some form of instability or catastrophe delimiting the range of stability of the crystalline state These are exemplified by the vibrational instability proposed by Lindemann[1] and the elastic shear instability of Born[2]. Fecht and Johnson[3] suggested that an entropy catastrophe delimits the stability range of both a superheated crystal and a supercooled liquid Drawing on Kauzmann's idea[4] that the glass transition pre-empts a catastrophe point at which the entropy of supercooled liquid equals that of the crystal, they suggest that a second catastrophe point occurs when the entropy of the superheated crystal equals that of the liquid phase, and that this is pre-empted by melting Here I argue that these entropy catastrophes are an outer bound on the stability limits of the crystalline and liquid phases, and that a hierarchy of inner catastrophes occurs at reduced superheatings or supercoolings

Kauzmann showed that, with progressive supercooling, the entropy of a liquid tends towards the entropy of the crystalline state Were they to cross at some temperature T_g, one would be faced with Kauzmann's paradox that, at temperatures below T_g, the entropy of the ordered crystal would exceed that of the disordered liquid This situation is prevented by the occurrence of the glass transition Although the glass transition may be loosely termed a 'kinetic transition', reflecting the fact that the structural relaxation time becomes so long that fluidity is lost, it is seen from Kauzmann's ideas that there is an underlying instability The kinetic character means that the observed transition point depends on the cooling rate but, in the limit o infinitely slow cooling, the transition point must remain greate than or equal to the instability point Moreover, one consequence of the free-volume theory of the glass transition is the prediction of an underlying first- or second-order transition[5] Thus, there appears a succession of catastrophe barriers to supercooling, first kinetic (corresponding to the glass transition), then thermodynamic and finally entropic (corresponding to the Kauzmann point) If one barrier were to be surmounted, the next would provide the natural ultimate limit for further supercooling Here I show that further barriers may be deduced and that a similar hierarchy of catastrophes occurs in relation to superheating of

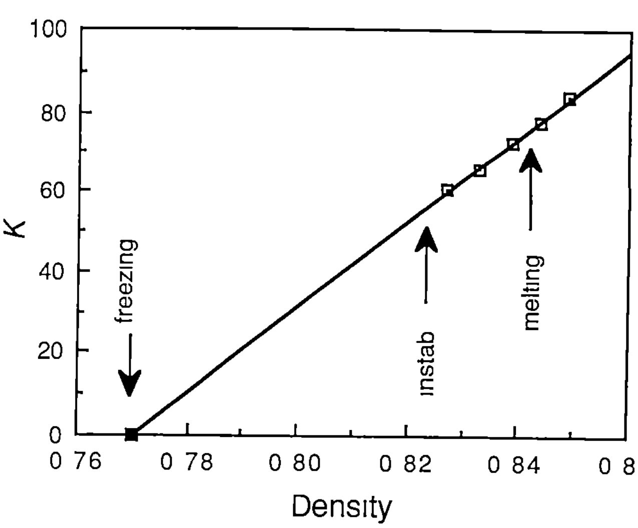

FIG 1 The Kosterlitz-Thouless parameter K as a function of reduced density for a computer-simulated two-dimensional crystal of Lennard-Jones atoms The solid data point shows that the crystalline data extrapolate to zero at the freezing density Densities are quoted in reduced units The equilibrium freezing and melting points are indicated together with the shear-instability point for maximum superheating

Permanent address Physics and Engineering Laboratory DSIR PO Box 31313 Lower Hutt New Zealand crystals, that is, to melting and the metastable extent of the crystalline phase

The interpretation of melting in terms of a one-phase instability model carries with it a number of problems Born's idea[2] that the shear modulus falls with increasing temperature becoming zero at the melting point T_m is evidently incorrect, or at least incomplete, as crystals still possess rigidity close to T_m Mechanical instability models imply second-order melting with marked pre-melting behaviour[6] rather than the observed first-order melting with little or no pre-transitional behaviour[7] Finally, the notion of crystalline instability refers only to the properties of the crystalline phase and any rigorous treatment of melting must also refer to the properties of the liquid phase The melting point is defined as the temperature and pressure at which the Gibbs free energy of the two phases are equal and beyond which thermodynamic instability occurs Nonetheless the notions of thermodynamic instability and mechanical instability can be harmonized and the two shown to coincide in a special sense To develop these ideas I use two previously reported results

First, if one examines the shear or rigidity moduli as functions of molar volume for a large range of cubic or close-packed solids, one of the moduli extrapolates to zero at the volume of the liquid at the freezing point[8 9] To illustrate this I have examined computer-simulation data for a two-dimensional Lennard-Jones system and find exactly the same result as previously reported[8 9] for real three-dimensional systems The data are the results of Monte Carlo calculations[10] of the elastic Lamé coefficients μ and λ for a 529-atom system close to the triple-point The Kosterlitz–Thouless parameter K defined by

$$K=\frac{4a^2}{kT_\mathrm{m}}\frac{\mu(\mu+\lambda)}{(2\mu+\lambda)} \tag{1}$$

is plotted in Fig 1 as a function of density Here a is the lattice parameter and k is Boltzmann's constant In Fig 1 the equilibrium thermodynamic melting density and freezing density are marked, together with the instability density at which the superheated crystal spontaneously melts by the generation of dislocations This instability point corresponds to a value of K close to the value 16π predicted theoretically[11] The value of K for the crystal extrapolates to zero at the freezing point density This means that Born's idea, that melting coincides with the vanishing of a shear modulus, is essentially correct except that this occurs near the freezing point rather than the melting point (note that these do not coincide in T, P, V phase space) We have argued[8] that the appearance of the communal entropy, once rigidity is lost, allows the system to discontinuously transform from a higher density to this critical density at the freezing point where the rigidity modulus vanishes The shear instability, properly interpreted, thus naturally gives rise to a first-order melting transition for two dimensions as well as for three dimensions In conventional isothermal melting the instability occurs within the solid–liquid interface, a region that is effectively superheated as its density is lower than that of the crystal

Second, we have shown that the entropy change ΔS on isochoric (that is constant volume) melting for a large range of simple crystalline materials is a constant equal to $\sigma R \ln 2$ where σ takes the value 1 for monatomic systems, 2 for binary systems and so on[12 13] This has been demonstrated for the inert gases, alkali metals, alkali and alkali earth halides as well as a variety of computer-simulated systems that is, for all systems with approximately spherical atoms Subsequent investigations of molecular-dynamics-simulated systems showed that this entropy change was just the communal entropy of the dense liquid[13] Thus, to a good approximation, the only difference in entropy between liquid and crystal at the same density is the communal entropy of the liquid This reduces to zero in at least three distinct transitions[13,14] the glass transition[14] (and as a consequence there is essentially no entropy difference between glass and crystal at the same density), in the superfluid transition[13] for ^{4}He, and in the fast-ion transition of an ionic crystal[13]

Where liquid and crystal are not at the same density the entropy difference may be well approximated by noting that the isothermal volume dependence of the entropy is given by $(\partial S/\partial V)_T=\alpha_\mathrm{v}\beta_T$ where α_v is the volume coefficient of thermal expansion and β_T is the isothermal bulk modulus The product $\alpha_\mathrm{v}\beta_T$ is nearly constant from above the Debye temperature to the melting point and takes nearly the same value in the melt It is not unexpected, therefore, that we find

$$\Delta S_\mathrm{m}=\alpha_\mathrm{v}\beta_T\Delta V_\mathrm{m}+\sigma R\ln 2 \tag{2}$$

an excellent approximation for the entropy change on melting This relation is well satisfied for all of the simple systems noted above with approximately spherical atoms[12]

Some simple conclusions using the above results Figure 2 is a reproduction of Fecht and Johnston's[3] diagram of the temperature dependence of the entropy of crystalline (curve C–C′) and liquid (curve L–L′) aluminium (Their calculated extrapolations are estimates only and aluminium, because of its non-spherical atoms, is not a good choice for applying the above simple phenomenology The diagram is, however, appropriate for illustrative purposes) Fecht and Johnston identified two catastrophe points, marked T_g^s and T_m^s in the figure, at which the entropies of the two phases are equal By subtracting the communal entropy, 0 69 R, from the entropy in the liquid phase I obtain the light solid line annotated G–G′ This represents the entropy of the liquid over the entire temperature range if the liquid were non-diffusive, that is, if the atoms were constrained to remain within their individual shells of neighbouring atoms Such a system is equivalent to a glass The entropy on this curve, according to equation (2), differs from the crystalline entropy by a volume-dependent term only, and consequently at the two

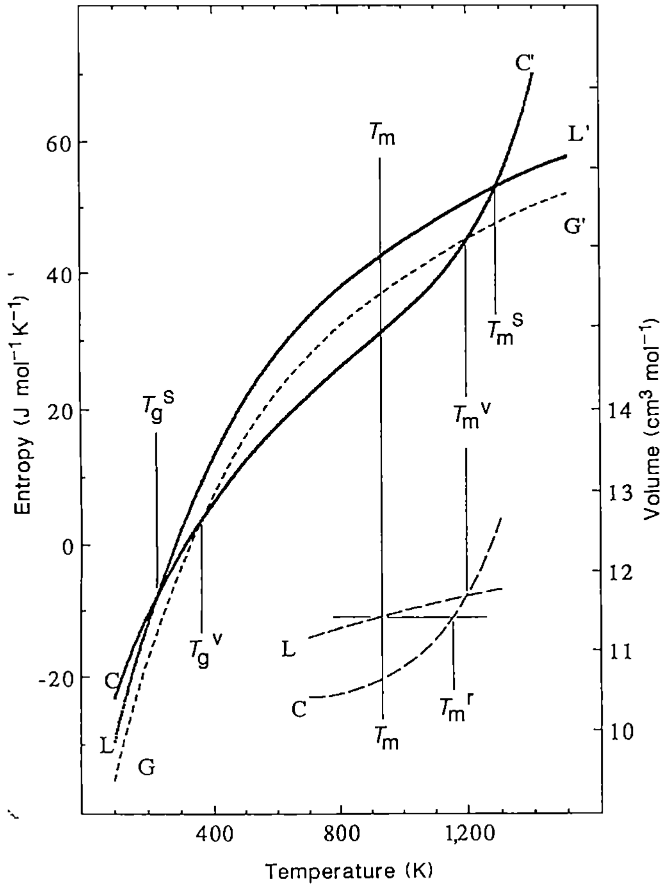

FIG 2 The calculated entropy and molar volume for aluminium in the crystalline (C) and liquid (L) phases at 1 bar See text for explanation

points marked T^{v}_{g} and T^{v}_{m}, where the curve G-G′ intersects C-C′, the crystalline and liquid phases have the same molar volume or density Beyond these points the crystal would be less dense than its liquid phase at the same temperature and for a close-packed crystal this is quite unexpected These two points therefore represent further catastrophe points, the boundaries of regions of paradox comparable to those of Kauzmann (There are materials for which the density of the liquid exceeds that of the crystalline solid[6], including Ga, Bi, Sb, H_2O and KI at elevated pressure, but these cases arise from the occurrence of a very open crystalline structure)

Having identified the two isochoric catastrophe points at which crystal and liquid possess the same density and which preempt the isentropic catastrophe points, I can estimate from these entropy curves the molar volumes of the two phases as they vary with temperature The object of this last calculation is to locate the point of rigidity instability which, according to the above ideas, occurs where the density of the superheated crystal equals that of the liquid at the freezing point For a non-isothermal process

$$\begin{aligned}\Delta S &= \alpha_v\beta_T\Delta V + \int (C_v/T)\,\mathrm{d}T \\ &\approx \alpha_v\beta_T\Delta V + C_v\ln(T/T_0)\end{aligned}\tag{3}$$

The latter approximation applies if C_v is constant, as may be assumed well above the Debye temperature Taking T_0 as T_m, the crystalline and liquid volumes are estimated from curves G-G′ and C-C′ by subtracting $C_v\ln(T/T_m)$ and dividing by $\alpha_v\beta_T$ These are plotted as the dashed lines in Fig 2, to which the volume scale on the right-hand side applies The point T at which the volume of the superheated crystal equals the volum of the liquid at the freezing point is marked This is the poi at which the rigidity modulus vanishes and shear instabili occurs, and this precedes both other catastrophe points T^{v}_{m} an T^{s}_{m} I note that the calculations of Boyer[15] indicate that th occurrence of a shear instability drives a preemptive instabilit in the compressibility Thus, for crystalline superheating a su cession of catastrophes occur in the sequence thermodynami (equilibrium melting), elastic compressibility, elastic rigidit isochoric (equal volumes for crystal and liquid) and finall entropic points I believe that the last two catastrophes are n observable as they are preceded by the rigidity catastrophe whic is the underlying cause of melting [

Interhemispheric asymmetry in climate response to a gradual increase of atmospheric CO_2

R. J. Stouffer, S. Manabe & K. Bryan

Geophysical Fluid Dynamics Laboratory/NOAA, Princeton University, Princeton, New Jersey 08542, USA

THE transient response of a coupled ocean–atmosphere model to an increase of atmospheric carbon dioxide has been the subject of several studies[1–8]. The models used in these studies explicitly incorporate the effect of heat transport by ocean currents and are different from the model used by Hansen *et al*[9] Here we evaluate the climatic influence of increasing atmospheric carbon dioxide using a coupled model recently developed at the NOAA Geophysical Fluid Dynamics Laboratory. The model response exhibits a marked and unexpected interhemispheric asymmetry In the circumpolar ocean of the Southern Hemisphere, a region of deep vertical mixing, the increase of surface air temperature is very slow. In the Northern Hemisphere of the model, the warming of surface air is faster and increases with latitude, with the exception of the northern North Atlantic, where it is relatively slow because of the weakening of the thermohaline circulation

The model we use here consists of general circulation models (GCMs) of the atmosphere and oceans and a simple model of the continental surface that involves the budgets of heat and water It is a global model and includes realistic geography The atmospheric component of the model used here is very similar to the model used in ref 10 The seasonally varying insolation at the top of the model atmosphere is taken into account in calculating the solar radiation Whenever the relative humidity at a grid point exceeds a critical value (99%), the grid box is filled with cloud, otherwise, it is free of cloud The atmospheric GCM uses a spectral transform method in which the horizontal distributions of predicted variables are represented by spherical harmonics (15 associated Legendre functions for each of 1 Fourier components) and grid-point values For vertical-finite difference calculations, nine unequally spaced levels are chosen The ocean GCM uses a full finite-difference technique and ha a regular grid system with 4 5°×3 75° (latitude×longitude spacing and 12 vertical levels[11] The atmospheric and oceani components of the model interact with each other continuousl through the exchange of heat, water and momentum fluxes

Two 100-year integrations of the coupled model were performed In the first integration the atmospheric concentratio of carbon dioxide increased by the rate of 1% yr^{-1} (compounded) The CO_2 concentration remains unchanged in the secon integration (the control) We have evaluated the influence o

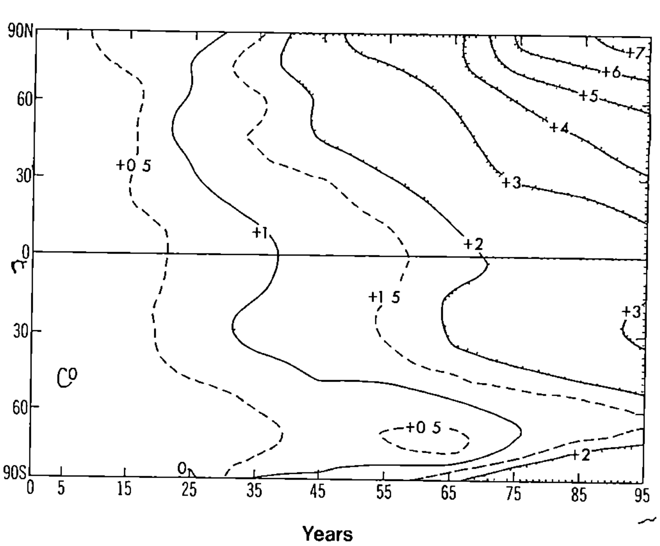

FIG 1 Latitude–time distribution of the difference in zonally averaged, decadal-mean surface air temperature (°C) between the two integrations Zonal-mean surface air temperature is averaged over the decades centred at the fifth, fifteenth , and ninety-fifth year of the experiment

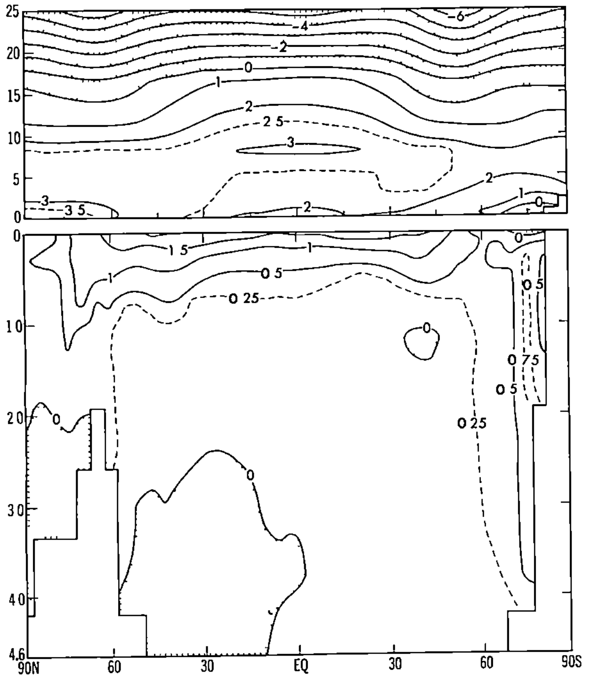

FIG. 2 Zonal-mean difference in temperature (°C) of the ocean–atmosphere model between the two integrations. The difference represents the decadal average over years 61–70. The atmospheric data have been interpolated to isobaric surfaces.

gradually increasing atmospheric carbon dioxide upon the coupled system from the difference between the first and second (control) integrations. If the CO_2 increase of 1% yr^{-1} begins in AD 1958, the doubling of CO_2 concentration would be achieved around AD 2030. Such an increase of CO_2 is larger than its projected increase but is approximately equal to the present rate of increase of the combined thermal forcing of all greenhouse gases (other than water vapour)[12].

The initial conditions for both integrations have realistic seasonal and geographical distributions of surface temperature, surface salinity and sea ice, with which both the atmospheric and oceanic components of the model are nearly in equilibrium. This quasi-equilibrium condition was obtained by separate time integrations of these two components of the model using observed surface conditions. The convergence of the oceanic component towards equilibrium was accelerated by the method described in ref. 13.

To avoid the systematic climate drift caused by the bias of the model during the two 100-year integrations, the oceanic surface fluxes of heat and water are adjusted seasonally and geographically, but not interannually, using the method described in ref. 14. Identical adjustments are applied to both the first and the second integrations defined above. By contrast to recent studies[4,8], no systematic trends are evident during the control integration, indicating that the initial condition is close to stable equilibrium and the flux adjustments are working as expected.

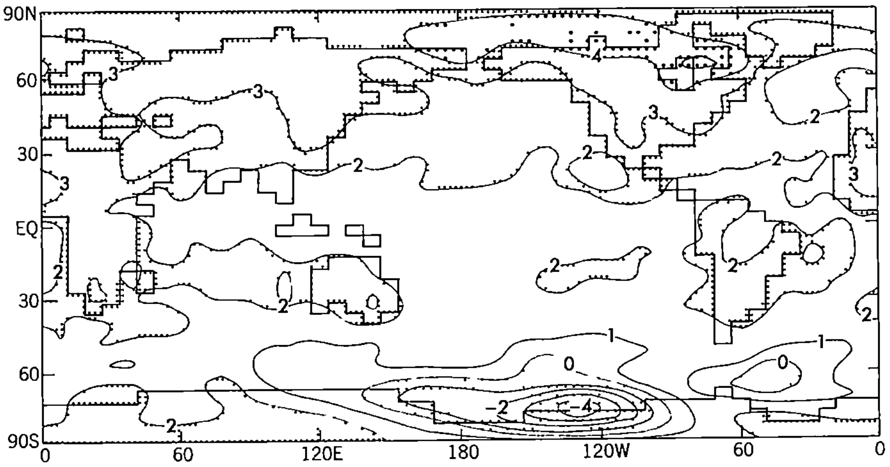
Figure 1 shows the latitude–time distribution of the CO_2-induced change of zonally averaged, decadal-mean surface air temperature during the 100-year experiment. In the Northern Hemisphere the warming of surface air increases with latitude, partly because of the poleward retreat of both snow cover and sea ice which have high surface albedo. The relatively large warming in high northern latitudes is essentially confined to the lower troposphere because of the stable stratification. This is indicated in Fig. 2 which shows the difference in zonal-mean temperature between the two integrations for the seventh decade of the experiment. The ocean warming is essentially confined to the upper layer, except near Antarctica. It also increases with latitude in the Northern Hemisphere, but becomes small near the North Pole which is covered by sea ice.

The meridional profile of the near-surface warming in the Northern Hemisphere is qualitatively similar to the difference between two equilibrium climates of a model with the normal and the above-normal concentrations of atmospheric CO_2 (See, for example, refs 15, 16, studies that were conducted using an atmosphere/mixed-layer-ocean model and atmosphere–ocean GCM, respectively.)

Over the northern North Atlantic, the increase of surface air temperature is significantly smaller than the zonal average. This is evident in Fig. 3 which shows the geographical distribution of the difference in decadal-mean surface air temperature between the two integrations for the seventh decade of the experiment. Because of the increase in runoff and precipitation over evaporation, surface salinity decreases and the stability of upper ocean layer increases in the northern North Atlantic. Thus, the thermohaline circulation of the North Atlantic is weakened by ~25% by the seventh decade of the experiment. The weakening is shown in Fig. 4 which illustrates the meridional circulation zonally averaged over the entire oceanic segment of a latitude circle. (Note the reduction from 16 to 12 Sv in the Northern Hemisphere.) Because of the weakening of the thermohaline circulation, the northward advection of warm and saline subtropical surface water is reduced, thereby reducing surface salinity further and making the increase of sea surface temperature relatively small over the northern North Atlantic Ocean as indicated in Fig. 3. The reduction of surface salinity stabilizes the near-surface layer and provides a feedback that further weakens the thermohaline circulation in the northern North Atlantic.

In an earlier study, Bryan and Spelman[3] investigated the

FIG. 3 The geographical distribution of the difference in surface air temperature (°C) between the two integrations averaged over years 61–70.



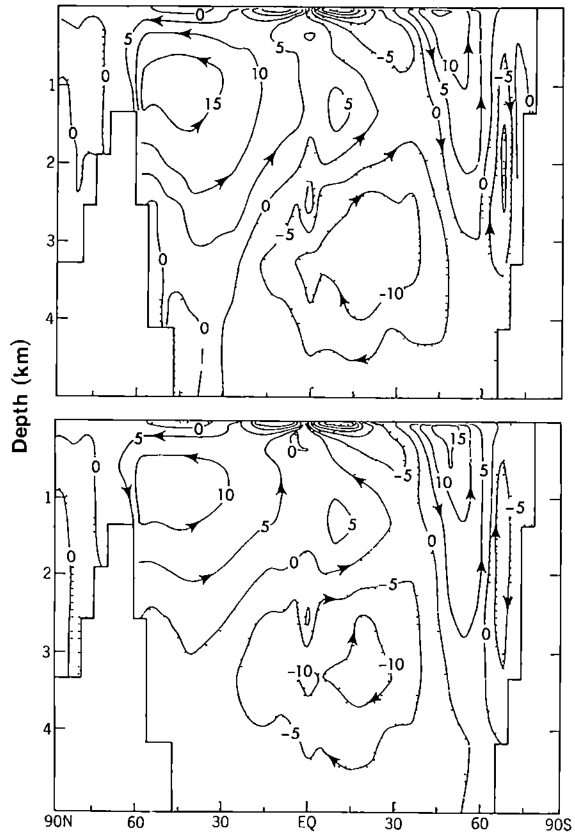


FIG 4 Streamlines of zonal-mean meridional oceanic circulation (in Sverdrups) averaged over the seventh decade (that is, years 61-70) of the experiment Top, the control integration with constant CO_2, bottom, the integration in which atmospheric CO_2 concentration is increased with the rate of 1% yr^{-1}

influence of an abrupt quadrupling of atmospheric CO_2 on the climate of an atmosphere-ocean model with a sector computational domain bounded by the Equator and two meridional boundaries They found that the thermohaline circulation of the model collapsed completely towards the end of the third decade of the experiment Washington and Meehl[8] noted that the response of their global model to a linear increase of atmospheric CO_2 was a weakening of the thermohaline circulation in the Atlantic Manabe and Stouffer[14] found that their global model has two stable equilibria, one with and one without the thermohaline circulation in the Atlantic Ocean Although we do not observe a complete collapse of the thermohaline circulation here, it is a possibility that deserves[17] further assesment

In the Southern Hemisphere, the CO_2-induced warming of surface air decreases with increasing latitude in sharp contrast to the situation in the Northern Hemisphere and to the results of equilibrium experiments The rate of the warming is particularly slow in the Antarctic circumpolar ocean A similar feature is noted and analysed in studies[6,7] that explored the effect of an abrupt doubling of the atmospheric CO_2 on coupled models with 'sector' and global computational domain, respectively The latter model is very similar to the present model except that it has annual-mean insolation The fraction of the area covered by oceans in the Southern Hemisphere is much larger than the corresponding fraction in the Northern Hemisphere Thus the effective thermal inertia of the Southern Hemisphere tends to be larger than in the Northern Hemisphere[18], accounting for the slower rise of surface air temperature in the former

Based upon a detailed study of the heat budget[6,7] there is another important mechanism responsible for the interhemispheric difference of effective thermal inertia particularly in high latitudes From 45°-65° S, the strong surface westerlies induce an Ekman drift current towards the Equator Because of the absence of a continental barrier in the upper oceanic layer, the zonal pressure gradient is small at the latitudes of the Drake Passage and the southward geostrophic return flow is weak beneath the surface mixed layer Instead, the surface drift currents are compensated by a deep downwelling north of the Drake Passage gap, southward geostrophic flow at the base of the gap, and deep upwelling south of the circumpolar current, as indicated in Fig 4 The existence of such an upwelling region is inferred[19,20] from water mass analysis A deep wind-driven cell is also simulated by eddy-resolving, high-resolution models[21] In addition to the wind-driven deep cell of meridional circulation described above, we note that (Fig 4) there is another cell circulating in the reverse direction in the immediate vicinity of Antarctica where deep convective overturning prevails, forming the Antarctic bottom water These deep cells of meridional circulation together with associated convective overturning and other sub-grid-scale mixing processes enhance the vertical mixing of heat over a thick ocean layer, thereby increasing the effective thermal inertia of the coupled ocean-atmosphere system This large effective thermal inertia is responsible for the very slow rise of the near-surface temperature in the circumpolar ocean of the model It is likely that a similar effective vertical mixing is also realized in the actual circumpolar ocean which is characterized by relatively small vertical variations of density and other trace substances such as phosphate and ^{14}C

The marked interhemispheric asymmetry of our result differs from the study of Schlesinger *et al*[4] in which an almost symmetric response was obtained A recent result[8] indicates smaller warming in the Southern than in the Northern Hemisphere However, the asymmetry is much less pronounced than in the present results This discrepancy may result from the fact that the wind-driven cell in the circumpolar ocean obtained in the earlier studies is much weaker and shallower than the cell simulated by the present model Obviously, a careful comparison of results is needed to determine the underlying cause of this discrepancy

Further evaluation of the mechanisms involved in the effect of ocean circulation on the CO_2-induced climate change is in progress The general applicability of the present results will be evaluated by conducting further simulations with different rates of CO_2 change and with models of higher computational resolution □

SULPHATE attack is a significant problem which locally affects concrete and other construction materials in the United Kingdom and overseas. The mechanisms of sulphate attack are fairly well understood, but in some instances it has proved difficult to establish the origin of the sulphate Possible sulphate sources include soils and ground water, sea water, atmospheric pollution, contaminated ground-fill and highway de-icing salts Here we show that stable-sulphur-isotope analysis can help to identify the causes of sulphate attack We carried out this investigation primarily to determine whether sulphate impurities in rock salt used for winter maintenance of the roads could be responsible for higher than expected sulphate levels that have been observed in parts of some road bridges Our sulphur isotope results indicate that this is not the case, and indicate that atmospheric sulphate sources are more important

Sulphate attack can cause serious deterioration of hardened concrete, render and mortar[1-3] Both chemical and mechanical mechanisms may be involved In the presence of dissolved sulphates, the constituents of hardened Ordinary Portland Cement (OPC) paste are progressively chemically altered to form secondary minerals such as ettringite, thaumasite and gypsum[3 4] These changes can cause expansion, cracking and loss of cement-like characteristics and may ultimately lead to total failure of the structure The extent and rate of chemical alteration is dependent on the concentration and type of sulphate in solution Sulphate concentrations as low as 0 3 g l^{-1} can pose a significant threat to concrete made with OPC[5] Magnesium and ammonium sulphate solutions pose the greatest threat because they react chemically with all of the compounds present in hydrated OPC Sodium sulphate solutions only attack the tricalcium aluminate hydrate and calcium hydroxide components, whereas calcium sulphate solutions react only with tricalcium aluminate hydrate[1 2]

In some circumstances three physical mechanisms also contribute to the deterioration[6-8] (1) stress generated by salt crystallization from a saturated or supersaturated solution, (2) stress generated by thermal expansion of salt crystals, (3) stress caused when certain salts undergo an increase in volume during hydration The relative importance of these mechanisms is dependent on the nature of salts present, on fluctuations in ambient temperature and humidity, and on the physical characteristics of the material being attacked[7 8]

In assessing the likelihood or cause of sulphate attack it is therefore important to identify the type, concentration and origin of sulphates that may come in contact with the structure

Sulphate can be derived from several sources including naturally saline soils and ground water, sea water, atmospheric pollution, industrial effluents, ash and other solid wastes used as foundation material, oxidation of pyritic shales, oxidation of sulphide inclusions in concrete aggregates, highway de-icing salts, agricultural fertilizers and effluents, and bacterial degradation of sewage sludge[9-12] Chemical analysis of soils and ground waters, combined with petrographic examination of the concrete, normally allows some possible sulphate sources to be eliminated Here we show that stable-sulphur-isotope analysis can also assist in identifying the source of sulphate that has invaded concrete and related structures

The near-surface concrete in road bridges is quite frequently found to contain higher than expected levels of sulphate The cement in hardened OPC concrete normally contains 2 5–2 9% (average 2 7%) sulphate expressed as SO_3, but sulphate levels sometimes exceed 4 5% SO_3 by weight of cement in the outer parts of concrete structures that are 15–20 years old[13] On parts of the structures that are not in contact with soils or ground water, locally high sulphate levels might be explained by one of three factors (1) redistribution of sulphate originally present in the concrete by fluid migration, (2) ingress of sulphates present in de-icing salt solutions, (3) ingress of sulphur species from the atmosphere Here we identify the relative importance of these three possible sources in contributing to high sulphate levels that were found during an investigation of a number of Cambridgeshire bridges[13]

Most of the salt used for winter maintenance of the roads in the United Kingdom, including Cambridgeshire, is Triassic rock salt from the ICI Meadowbank mine at Winsford, Cheshire[14] This salt contains sulphate impurities mainly in the form of anhydrite ($CaSO_4$) Anhydrite is also the dominant sulphate impurity in de-icing salt from other sources used in the United Kingdom

To determine whether rock salt has contributed significantly to higher than expected sulphate levels found in the Cambridgeshire bridges studied, $\delta^{34}S$ values (defined in Table 1 legend) were determined for 44 samples of concrete, de-icing salt and other sulphate-bearing materials found in association with degraded concrete from a number of known environments A full list of the samples is given in Table 1

All of the samples were oven dried at 80 °C for 24 h, ground to pass a 0 1-mm sieve and boiled in 10% (v/v) HCl for 20 min to extract the sulphate After filtering, the acid-soluble sulphate was precipitated by addition of 5% (w/v) $BaCl_2$ solution The resulting $BaSO_4$ precipitates were then washed with de-ionized water and dried at 80 °C The $^{34}S/^{32}S$ ratios were determined by mass spectrometry performed on the SO_2 obtained by heating the $BaSO_4$ to ~1,400 °C (refs 15, 16) The overall reproducibility of a $BaSO_4$ standard was better than ±0 3%

The results showed the following (Fig 1) (1) samples of unhydrated OPC and pristine hardened concrete obtained from cores in Cambridgeshire bridges have $\delta^{34}S$ values of +10 to +14 5‰, (2) the samples of black ash, shale, clay and brick, which contain reduced sulphur compounds or oxidation prod-

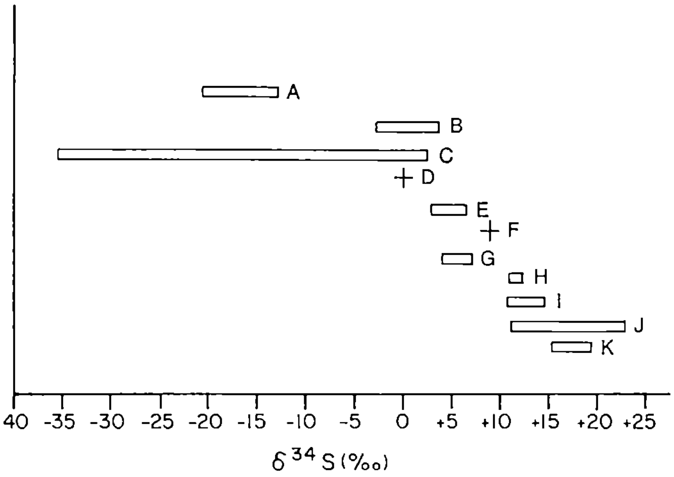

FIG 1 $\delta^{34}S$ values for A, brick (flettons), B, render affected by sulphate from brick/atmospheric sources, C, clay, shale and industrial ash ground-fill, D, concrete affected by sulphate from ash-fill, E, gypsum crusts on limestone buildings, F, sewer concrete affected by sulphuric trade effluent, G, deteriorated concrete, affected by atmospheric sulphate, H, pristine concrete, Peterborough, I, unhydrated OPC, J, other UK and overseas de-icing salt, K Cheshire de-icing salt

TABLE 1 Results of sulphur isotope analysis

Sample No	Nature of material	$\delta^{34}S$ (‰)*

* $\delta^{34}S = [(^{34}S/^{32}S)_{sample}/(^{34}S/^{32}S)_{standard}] - 1$, where we have used the Canyon Diablo Troilite (CDT) standard

ucts derived from them, have $\delta^{34}S$ values in the range −36 to +2.6‰, (3) concrete samples known to have suffered contamination by ingress of sulphates derived from the above sources have $\delta^{34}S$ values of −7 to +3.8‰, (4) gypsum crusts that have formed on the upper parts of limestone buildings in Cambridge because of the deposition of atmospheric sulphate have $\delta^{34}S$ values of +4 to +6.8‰, (5) deteriorated concrete from high levels on blocks of flats, which have also been affected by ingress of atmospheric sulphate, have $\delta^{34}S$ values of +5.9 to +7‰, (6) Cheshire rock salt supplied for winter maintenance of the roads has typical $\delta^{34}S$ values of +15.2 to +18.9‰, (7) samples of de-icing salt from a number of other mines in the United Kingdom and overseas, which are used less widely for winter maintenance, possess $\delta^{34}S$ values of +10.2 to +22.8‰, (8) samples of deteriorated concrete from bridges in the Peterborough area, which were found to have higher than expected sulphate levels but where the source of the extra sulphate was uncertain[13], has $\delta^{34}S$ values of +4.7 to +7.1‰.

These results clearly indicate that de-icing salt could not have contributed significantly to the elevated sulphate levels in the Cambridgeshire bridges investigated, because the rock salt has more positive $\delta^{34}S$ values, and the sulphate-contaminated concrete lower positive values, than the pristine hardened concrete, which has not been affected by ingress of external sulphate, at depths of 150–180 mm in these structures. The results also indicate that the high sulphate levels in the outer 40 mm of concrete cannot be attributed to redistribution, during wetting and drying, of sulphate initially present within the concrete itself. As the near-surface concrete with high sulphate levels has lower $\delta^{34}S$ values than the pristine concrete at greater depth, the extra sulphate is most likely to have been introduced from atmospheric sources. This may include both dry deposition of sulphur dioxide and wet deposition of sulphur species in rainfall and spray thrown up by vehicles on the carriageway.

We conclude that sulphur isotope analysis can provide a useful tool in investigations to determine the causes of sulphate attack. Further work is required to determine whether atmospheric sulphur deposited by wet and dry processes can be differentiated and whether the incorporation of external sulphate in stone crusts and concrete involves any significant differences in isotope fractionation. □

Thermal control of basaltic fissure eruptions

Paul M. Bruce* **& Herbert E. Huppert**

Institute of Theoretical Geophysics, University of Cambridge

* Present address Shell International Petroleum Co Ltd, Shell Centre, London SE1 7NA, UK

As hot, basaltic magma rises in a newly opened dyke during an eruption, it flows through colder crustal rock. The flowing magma advects heat along the dyke, at the same time, heat is conducted out of the dyke into the colder surroundings. The loss of heat will lead initially to the channel becoming constricted by magma solidifying against the walls The channel may then become completely blocked, which will end the eruption at that site before the supply of magma is exhausted Alternatively, the continual supply of heat by the flowing magma may, after some time, exceed the losses into the country rock. In this case, the initial solidification is reversed, the walls of the channel are progressively melted and the dyke is widened until the supply diminishes We present here a model that quantitatively delineates these two regimes. We also identify an intermediate regime in which parts of the surface fissure may become blocked and the eruption continues from isolated vents

Basaltic eruptions display a fascinating variety of behaviours[1] The low viscosity of such lavas allows relatively steady degassing and flow, as opposed to the explosive eruptions characteristic of more viscous magmas 'Quiet' basaltic eruptions nonetheless evolve over time in a highly complex way Typically, a linear system of fissures opens rapidly and erupts a continuous 'curtain of fire' Small eruptions simply cease within half a day In larger eruptions activity begins, after several hours, to concentrate at certain points along the fissure[2,3] If eruption persists, it becomes localized at one or a few vents, building cones Preferential localization of subsequent fissure eruptions to the same areas produces substantial shield volcanoes In the extremely voluminous eruption at Laki in 1783, flow persisted at not one but dozens of vents along the fissure[4]

The initial formation of the dyke is the result of elastic processes in the surrounding country rock[5 6] We concentrate here on the primarily thermodynamic problem of determining both the flow in the dyke and its evolution after the initial rock propagation and widening have taken place Naive estimates of the solidification of magma against the walls of the dyke based solely on conduction[7], indicate that flow should effectively cease in a matter of days A previous model[8] which included some advective effects came to much the same conclusion unless brecciation of the dyke wall and local widening of the conduit by removal of the fractured blocks leads to increased flow rates[9] There are deficiencies in this model, however, most notably the neglect of both the latent heat of solidification and the effect of the thermal advection in the magma on the temperature profile of the solid These omissions consistently overestimate the tendency of the dyke to become blocked Our model includes both these effects and allows us to understand how meltback of the walls can actually occur

To obtain our results we analysed an initial-value problem for $\theta(x, z, t)$, the temperature in both the fluid and the solid with respect to locally cartesian coordinates z measured along the wall and x perpendicular to it, with $x=0$ at the wall In constructing the equations, we assumed that the flow in the thermal boundary can be represented by a shear flow of magnitude γ The governing equations then become

$$\theta_t - v\theta_x + \gamma x \theta_z = k\theta_{xx} \ (x, t>0) \tag{1}$$

$$\theta = T_m \ (z=0), \qquad \theta = T_w \ (x=0), \qquad \theta = T_m \ (t=0 \text{ or } x \to \infty) \tag{2}$$

$$\theta_t - v\theta_x = k\theta_{xx} \ (x<0, t>0) \tag{3}$$

$$\theta = T_w \ (x=0), \qquad \theta = T_\infty \ (t=0 \text{ or } x \to -\infty) \tag{4}$$

The velocity of migration of the interface between fluid and solid, v is proportional to the difference in the conductive heat flux across the wall and is determined from

$$(L/c)v = -\kappa[\theta_x(0+, z, t) - \theta_x(0-, z, t)] \tag{5}$$

The shear flow at the edges of the channel of width W is driven by a pressure difference ΔP and results in a volume flow rate $Q(t)$ These are related by

$$\Delta P = 12\mu Q(t) \int_0^h W^{-3}(z, t)\,\mathrm{d}z \quad \text{and} \quad \gamma(z, t) = 6W^{-2}(z, t)Q(t) \tag{6}$$

With either solidification or melting, the half-width gradually changes according to

$$W(z, t) = W_i - 2\int_0^t v(z, t')\,\mathrm{d}t' \tag{7}$$

The solutions to equations (1)-(7) were obtained numerically by integrating suitably simplified and non-dimensionalized versions which are formally valid for all time[10 11]

FIG 1 Cross-section through a typical sheet-like planar dyke Note that the dyke need not necessarily be vertical

We consider, as depicted in Fig 1, the dyke to be a two-dimensional channel the width of which is initially uniform but subsequently changes because of local solidification or melting The newtonian flow is considered to be laminar and the driving pressure is taken to be fixed Thus if the channel becomes constricted, the total flow rate decreases Cooling of the magma in the dyke is typically confined to a thin boundary layer adjacent to each wall The width of the boundary layer increases with length along the dyke and can attain a value of ~10 cm at the end of the dyke The difference between the heat supplied to the wall from this boundary layer and that conducted into the surrounding solid determines the rate of solidification or melting, which is directly proportional to the magnitude of the latent heat The temperature profile in the solid is determined numerically taking into account the effects of advection in the magma A full derivation of the governing equations and details of their solution are given in refs 10 and 11

The behaviour of the solutions is governed by three dimensionless parameters The first is the Stefan number of the magma, $S_m = L/(c(T_m - T_w))$, where L and c are the latent and specific heats per unit mass, T_m is the temperature of the magma at the entrance to the dyke and T_w is the temperature at the wall, which is defined as the temperature at which the crystallizing magma ceases to flow In fact, solidification and melting take place over a temperature range, this range is, however, typically small compared with the difference between T_w and T_∞, the far-field temperature in the crust, and hence can be neglected The second parameter governing the behaviour of the thermal processes is the Stefan number of the surrounding crust $S_\infty = L/(c(T_\mathrm{w} - T_\infty))$ This incorporates the approximation that the fluid magma, its solid product and the country rock have identical thermal properties The final parameter is $B = (W_\mathrm{i}^4/H^2)(\Delta P/\mu\kappa)$, where W_i is the initial width of the dyke of length H, ΔP is the driving pressure in the reservoir, μ is the mean value of the dynamic viscosity of the magma within the boundary layer and κ is the thermal diffusivity of both magma and country rock The cube root of B is the ratio of the initial width of the dyke to the initial width, at the top of the dyke, of the thermal boundary layer, due to advection before any solidification or melting can take place We assume that this ratio is large

We also assume that $c = 730\,\mathrm{J\,kg^{-1}\,°C^{-1}}$, $L = 8\times10^5\,\mathrm{J\,kg^{-1}}$, $\kappa = 10^{-6}\,\mathrm{m^2\,s^{-1}}$, $T_\mathrm{m} = 1{,}200\,°\mathrm{C}$, $T_\mathrm{w} = 1{,}150\,°\mathrm{C}$ and $\mu = 100$ Pa s (ref 12), which reflect values appropriate for a typical basaltic magma The driving pressure was evaluated from the lithostatic overburden[13] as $\Delta P/H = 2{,}000\,\mathrm{N\,m^{-3}}$, with H taken as either 2 or 5 km We chose these values because the depth interval 2-5 km corresponds to the top and bottom of active magma reservoirs in Hawaii, Iceland and the East Pacific Rise It also corresponds approximately to the upper surface and the keel of dykes in the respective rift zones of these localities In a given volcanic system the remaining two variables T_∞ and W_i determine the course of successive eruptions The value of T_∞ may vary between 0 and 1,150 °C (T_w) depending on the previous thermal history of the dyking zone With these values, $S_\mathrm{m} = 22$, S_∞ ranges upwards from 1 05 (which corresponds to cold country rock at 0 °C) and B can take on any positive value, though it must exceed unity for our boundary-layer model to be appropriate

The important qualitative behaviour of our two-dimensional model is sketched in Fig 2 This is augmented by the quantitative results depicted in Fig 3 When the eruption commences magma initially solidifies against the walls of the dyke In those dykes for which W_i and T_∞ are sufficiently small so that they fall below demarcation line AA′ for a 2-km dyke and BB′ for a 5-km dyke, solidification continues in the downstream portion of the channel The surface fissure will eventually become blocked and the eruption through the dyke feeding the fissure will cease irrespective of the magma supply If $T_\infty = 100\,°\mathrm{C}$, for a dyke 2 km long the critical initial width is 1 3 m, whereas for a dyke 5 km long the critical initial width is 1 7 m The time taken for the dyke to become blocked as a function of its initial width is shown in Fig 3*b* for these two dyke lengths

If ΔP remains fixed, eruptions can only continue from dykes whose initial width exceeds the critical value, which is decreased if the dyke is surrounded by warmer country rock This increase in T_∞ could be the result of pre-warming by previous dyking events or by hydrothermal circulation For dyke widths beyond the critical value the thermal energy from the reservoir advected along the dyke melts back the walls and the channel remains open Thereafter, the rate and duration of the eruption are controlled by the decay of the driving pressure ΔP and the possible closing of the dyke because of the resulting subsidence, which we have not included in our model When ΔP has decreased sufficiently solidification will take place once more and the eruption fade away

FIG 2 The evolution of a two-dimensional dyke *a*, State at an instant during initial development *b*, Development of blocking *c*, Development of turnaround and meltback

result of melting is broadly consistent with some previous observations Both the evolution of the Pu'u O'o series of en echelon dyke fissures in Hawaii (L Wilson, personal communication) and the final width of 25 m for some fissure dykes in Iceland (M R Ryan, personal communication) seem to be explicable only if melting back of the original dyke walls is postulated

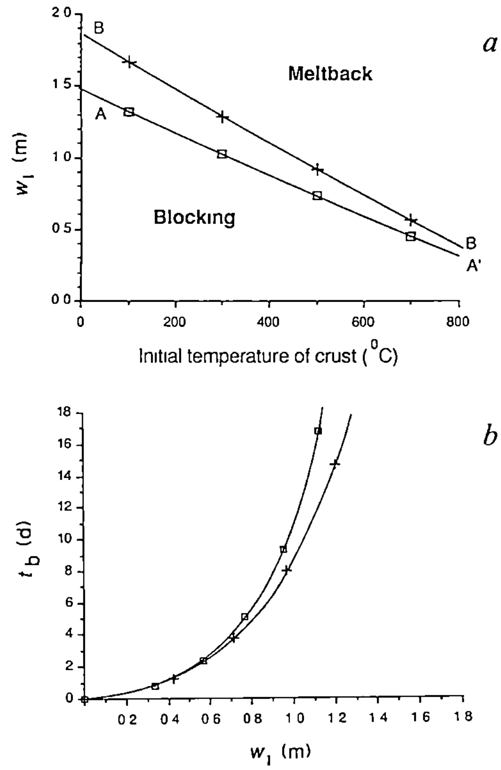

FIG 3 Numerical results of model, for parameter values given in text *a*, Regions of parameter space in which blocking or meltback are predicted for dyke length 2 km (squares) and 5 km (crosses) *b*, Time for dyke to become blocked as a function of initial dyke width, for $T_\infty = 100$ °C The time to block becomes infinite for widths approaching the critical value for meltback to occur (dotted lines (left) $H = 2$ km, dotted lines (right) $H = 5$ km) Symbols as in *a*

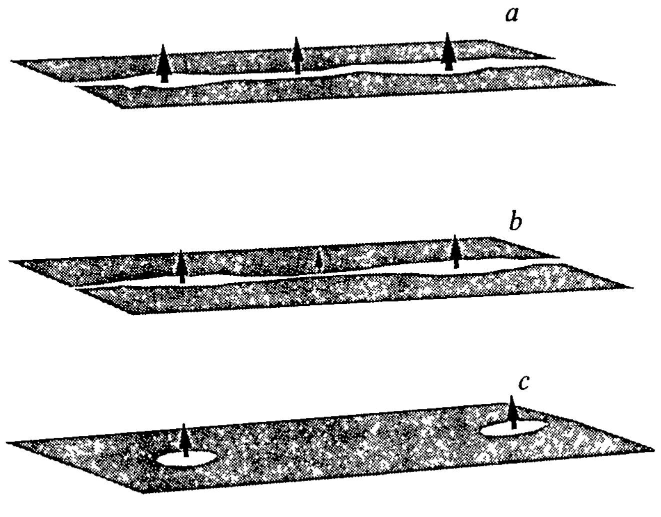

FIG 4 A schematic (not to scale) diagram of flow localization and development of a surface fissure over time *a*, initial irregularities of width (which may be small) *b*, faster solidification in narrow regions exaggerates the difference *c*, flow through isolated vents melts back walls and flow is blocked elsewhere

Further, the two-dimensional analysis quantifies an important feedback mechanism Decreasing the width of the dyke restricts the flow This reduces the advected heat supply which leads to further solidification and reduction of the width Correspondingly, widening the dyke by melting the walls increases the advected heat supply which results in further melting This feedback mechanism has an important role in a more realistic three-dimensional model, in which the width of the dyke varies, as depicted in Fig 4 Cross-flows between sections of different initial widths will form because flow through the narrow sections will encounter greater constrictions because of preferential solidification The cross-flows further reduce the advected heat flux in the downstream portions of the narrow sections and increase it at the wider portions, thereby exaggerating initially small differences in the width of the dyke (Fig 4*b*) Our model predicts that, as a result of this mechanism, many fissure eruptions of moderate size are localized at isolated vents over a period of days (Fig 4*c*), which is consistent with observations on Hawaii and elsewhere (refs 2, 3, 14 and T L Wright, personal communication) and with a previous qualitative discussion[15] Eruptions from these vents will persist until limited by other volcanic processes Sustained eruptions result in the formation of cylindrical conduits that are much wider than the original dyke and are preserved as volcanic plugs ☐

* National Institute for Environmental Studies, PO Tsukuba,
Ibaraki 305, Japan
† Ocean Research Institute, University of Tokyo, Nakano-ku,
Tokyo 164, Japan

STEADY-STATE emanations of hydrothermal vent fluid along the mid-ocean ridges give rise to plumes rising 100–300 m above the sea floor, identified by anomalies of temperature, conductivity, chemistry and particles Recently, a quite different type of hydrothermal plume created by a brief but massive release of high-temperature hydrothermal fluids was discovered by Baker *et al.* at a Juan de Fuca vent field[1–3]. This gigantic thermal plume was termed a 'megaplume'. In December 1987, we found a large

---

§ Present address Tokyo University of Fisheries Minato-ku Tokyo 108 Japan

hydrothermal plume showing anomalies of temperature, methane and manganese above the North Fiji Basin spreading axis The transience of this plume at 173° 30′ E, 18° 50′ S was confirmed by our return visit to the site in November 1988 The discovery of megaplumes at two sites in very different tectonic environments indicates that this type of hydrothermal activity may make an important contribution to thermal and chemical fluxes from the mid-ocean ridges.

The North Fiji Basin is a 2,000–4,000-m-deep back-arc basin behind the active subduction zone of the Vanuatu Arc (Fig 1*a*) with a spreading rate[4] of ~7 2 cm yr^{-1} In December 1987, the 'Kaiyo 87' cruise was conducted (the STARMER project[5]) to locate the recent spreading axis more precisely[6] The cruise followed up the results of a previous survey[4] (SEAPSO leg 3, December 1985) Here we describe the results of conductivity-temperature-depth (CTD) profiling and water sampling and discuss the nature of the plumes observed

Because no precise vent locations had been discovered, we used eleven hydrocast stations along the ridge crest (Fig 1*b*) The background concentrations of Mn and CH_4 ranged from 0 4 to 1 0 nmol kg^{-1} and from 0 2 to 0 3 nmol kg^{-1}, respectively These are comparable with the background levels for deep waters of the open oceans[7,8] We observed Mn anomalies at all stations the Mn concentration increased with depth below 1,900 or 2,200 m The Mn concentrations of the bottom layer at the nine stations, located between 16° 54′ S and 18° 50′ S, ranged between 5 and 10 nmol kg^{-1} This indicates that the hydrothermal supply of Mn extends over a large area similar to the Juan de Fuca Ridge[9] The anomalies of Mn at the northernmost and the southernmost stations (stations 11 and 15) were the smallest

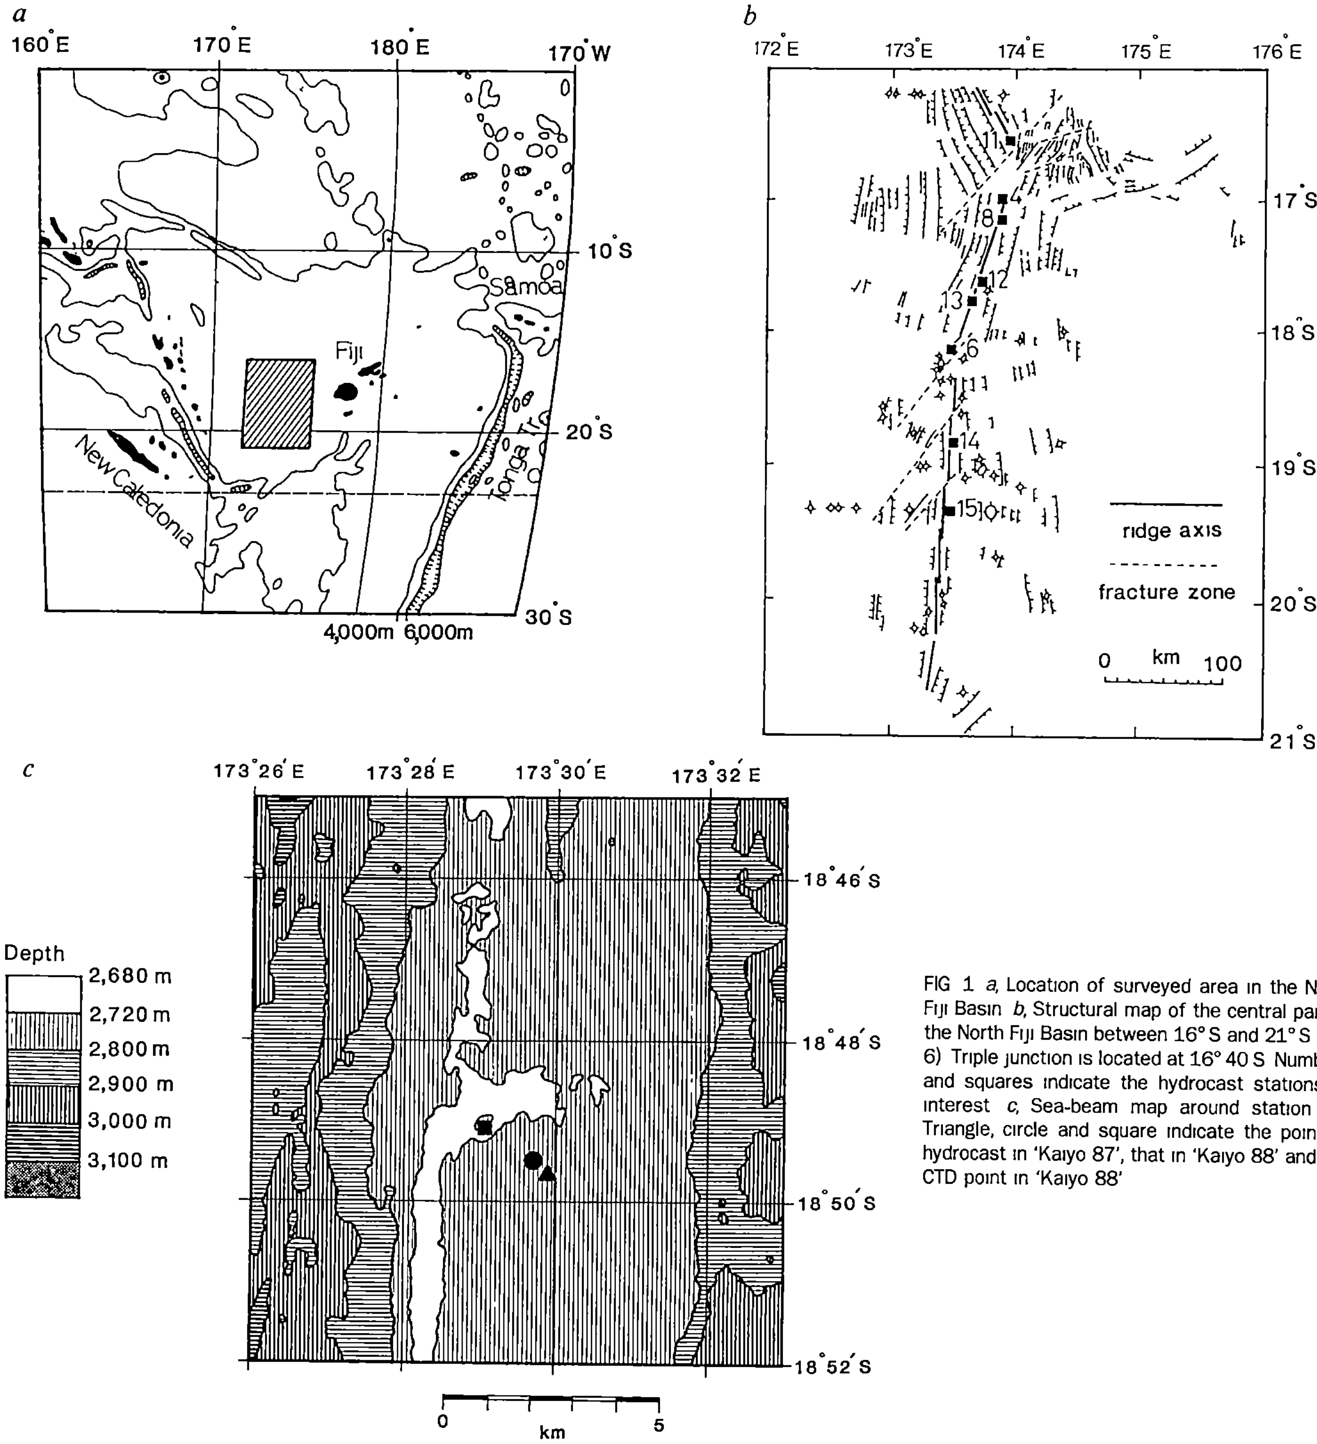

FIG 1 *a*, Location of surveyed area in the North Fiji Basin *b*, Structural map of the central part of the North Fiji Basin between 16° S and 21° S (ref 6) Triple junction is located at 16° 40 S Numbers and squares indicate the hydrocast stations of interest *c*, Sea-beam map around station 14 Triangle, circle and square indicate the point of hydrocast in 'Kaiyo 87', that in 'Kaiyo 88' and the CTD point in 'Kaiyo 88'

The plot of potential temperature θ against salinity S for the station 14 (triangle in Fig 1*c*, 173° 30′ E, 18° 50′ S, 29 December 1987) data is shown in Fig 2*a* The apparent distortion reflects the θ-anomaly that is due to the injection of hydrothermal water into the ambient sea water Figure 2*b* is the calculated profile of the excess temperature It shows a large plume, having a sharp peak 800 m above the sea floor and a broad peak 650 m above the sea floor There is another deeper plume 90 m above the sea floor The density-depth profile shows no inversion so these are neutrally buoyant plumes spreading along the isodensity surface The physical characteristics of the Juan de Fuca Ridge megaplume[2,3] are as follows to more than 800 m above the sea floor it is 700 m thick, has a 20-km-diameter spheroidal shape and a maximum θ-anomaly of 0 28 °C Beneath the megaplume, a separate deeper plume was observed The vertical scale and the θ-anomaly of the upper plume of station 14 are similar to those of the Juan de Fuca Ridge megaplume The deeper plume corresponds to the steady-state plume of the Juan de Fuca Ridge Smaller θ-anomalies were observed at station 8 and 13 At the other stations, smooth θ-S relationships were obtained

Figure 3 displays the Mn and CH_4 profiles at station 14 The upper large plume in 'Kaiyo 87' is characterized by a low Mn concentration but the deeper narrow plume shows a high Mn concentration The shapes of the vertical profiles of Mn in both the Juan de Fuca Ridge and the North Fiji Basin are very similar but the Juan de Fuca Ridge plumes had concentrations about seven times higher than that of the North Fiji Basin

The correlation of Mn and CH_4 concentrations for station 14 is plotted in Fig 4 along with those at station 12 in 'Kaiyo 87' At station 12, we found no θ-anomaly but the concentration of Mn increased gradually with depth below 2,200 m The linear CH_4/Mn relationship may represent an average injection ratio of CH_4 and Mn in the area The slope (0 121 mol mol^{-1}, regression line B in Fig 4) is the same as the averaged CH_4/Mn ratio (0 12 mol mol^{-1}) in the previous SEAPSO results[4] (Table 1)

The available data for the hydrothermal-supply ratios of CH_4/heat, Mn/heat and CH_4/Mn are summarized in Table 1 Regression line A in Fig 4 corresponds to the upper plume of station 14, which has a high CH_4/Mn ratio The regression line C corresponds to the deeper plume of this station, which has a low CH_4/Mn ratio We calculated the Mn/heat and CH_4/heat ratios for both plumes The relationship of Mn/heat ratio between the upper and lower plumes of station 14 corresponds to that between the megaplume and the accompanying steady-state plume of the Juan de Fuca Ridge[2,3]

We made a return visit to station 14 on 20 November 1988 during the 'Kaiyo 88' cruise (circle in Fig 1*c*) The distance between the two sampling points was only a few hundred metres, but we found no θ-anomaly The Mn profile in 'Kaiyo 88' is shown in Fig 3 (closed circles) The upper plume of the previous year had disappeared but a large Mn anomaly was observed near the sea floor We detected a small θ-anomaly of 0 02 °C, with a profile similar to the lower plume of the previous year, at a nearby CTD station (square in Fig 1*c*) We also detected vent animal communities (deep-tow camera observation) during 'Kaiyo 88' These observations indicate hydrothermal activity in the area It is likely that the 'Kaiyo 88' hydrocast detected

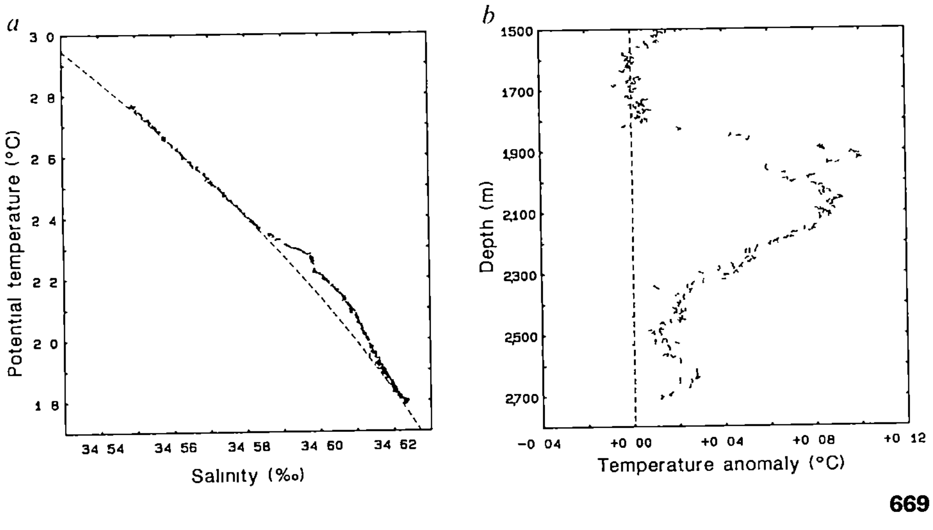

FIG 2 *a*, Potential temperature (θ) plotted against salinity (S) at station 14 of 'Kaiyo 87' Seabird model 9 CTD with rosette sampler was used The resolution of the thermometer and conductivity cell were 0 0003 °C and 0 00004 S m^{-1}, respectively Data obtained by CTD was averaged in every 1-m interval for water-column depths >1,500 m The broken line is the smoothed curve obtained from the θ-S relationship at station 15, the nearest station having no temperature anomaly to station 14 *b*, Vertical profile of excess temperature in the water column of station 14 of 'Kaiyo 87', calculated as a difference between the potential temperatures at stations 14 and 15 at the same salinity

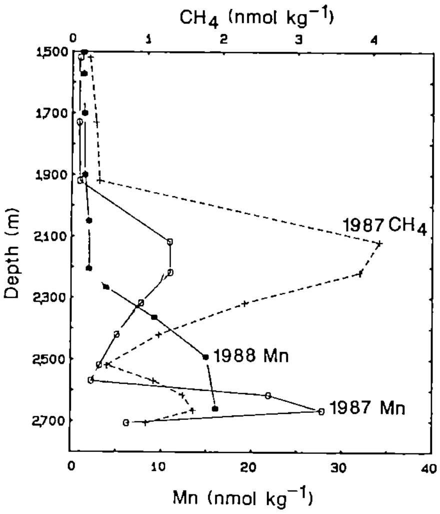

FIG 3 *a*, Vertical profiles of Mn and CH_4 at station 14 Open circles, crosses and closed circles are Mn of 'Kaiyo 87', CH_4 of 'Kaiyo 87' and Mn of 'Kaiyo 88', respectively Water samples were collected with Teflon-lined 8 l Go-Flo Niskin bottles mounted on rosette multi-sampler Mn in sea water was collected aboard ship on a Nucleopore membrane filter with added ferric hydroxide precipitate Mn in both dissolved and particulate forms are effectively separated from the seawater matrix The precipitate was dissolved in hydrochloric acid and analysed by inductively-coupled plasma emission spectrometry on shore Samples for CH_4 analysis were sealed in glass bottles with septum stopper after poisoning with $HgCl_2$ and preserved in a refrigerator until they were analysed on shore[16] The limit of determination of Mn and CH_4 analyses were both 0 1 nmol kg^{-1} The reproducibility of Mn analysis was 2% at 7 nmol kg^{-1}, but 10% at 1 nmol kg^{-1} CH_4 analysis was accurate within 4% at 1 nmol kg^{-1}

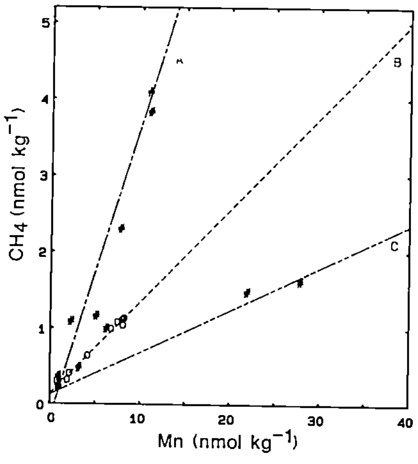

FIG 4 Correlation between Mn and CH_4 concentrations in sampled sea water of stations 12(o) and 14(#) of 'Kaiyo 87' cruise Regression lines were calculated for the data of stations 8, 12, 13 and 14 A, CH_4(nmol kg^{-1})= 0 386 ×Mn(nmol kg^{-1})−0 16 (correlation coefficient, r=0 90, number of points, n=9), B, CH_4(nmol kg^{-1})=0 121 ×Mn(nmol kg^{-1})+0 14 (r=0 99, n=11), C, CH_4(nmol kg^{-1})=0 056 ×Mn(nmol kg^{-1})+0 13 (r=0 93, n=9)

the steady-state hydrothermal effluent emerging at the spreading axis and that the upper plume of the previous year had disappeared

The identification of the upper plume of the 'Kaiyo 87' station 14 as a megaplume depends on its vertical scale, its large θ-anomaly, the low concentration of Mn and its absence in 'Kaiyo 88' These characteristics are similar to those of the Juan de Fuca Ridge megaplume During an earlier cruise, Craig *et al*[10] discovered a large plume having a very elevated concentration (13 nmol kg^{-1}) of CH_4 in the North Fiji Basin Our hydrocast at the location (station 6 in Fig 1*b*) revealed no plume-shaped anomaly of Mn and the CTD profile showed no temperature anomaly The CH_4 plume observed by Craig *et a* may have been another megaplume

The different Mn/heat ratio of the upper plume and lowe plume of station 14 could be a consequence of a different origi The extraction efficiency of Mn into vent fluid would depen on the reaction time of the fluid with hot basalt and the effectiv water/basalt ratio during plume formation The sudden catas trophic production of a megaplume might thus be expected t result in a low Mn/heat ratio compared with a steady-stat plume

The observations of megaplume-type hydrothermal effluen at different ocean ridges indicates that this type of hydrotherma activity may be a common phenomenon in rift systems Th possibility of a frequent occurrence of megaplumes is significan for the global hydrothermal fluxes of heat and chemical com ponents More extensive investigations of megaplumes especially of their frequency, spatial scale and chemical nature are necessary □

An unusual hopane biodegradation sequence in tar sands from the Pt Arena (Monterey) Formation

A. G. Requejo*† & H. I. Halpern*

* ARCO Oil and Gas Company, 2300 West Plano Pakway, Plano, Texas 75075, USA

HOPANES are ubiquitous in petroleum source rocks and crude oils These compounds are thought to be derived mainly from a specific oxygenated precursor, bacteriohopanetetrol, found in the cell walls of prokaryotic organisms[1], and commonly occur as a homologous series of structurally related isomers containing between 27 and 35 carbon atoms; hopanes containing more than 35 carbon atoms have also been reported[2]. Hopanes and other pentacyclic triterpanes are relatively resistant to microbial degradation[3–5], making them useful in correlating moderately biodegraded oils to their source rocks[5]. During the advanced stages of biodegradation, however, these compounds can be altered, being converted either to 25-normethyl homologues[4] or to other, as yet uncharacterized, products. Selective removal of individual compounds may occur; for example, 22*R* extended homohopanes may be degraded whereas 22*S* epimers are preserved[6–8]. Here we report an unusual biodegradation sequence of pentacyclic triterpanes in tar sands from the Pt Arena Formation, California, in which the 22*S* and 22*R* isomers of the 17α(H), 21β(H)-C_{35} extended hopanes are selectively preserved. Demethylation at the C_{25} position is observed for most hopanes in severely biodegraded samples, with

the exception of the C_{35} extended hopanes Two commonly occurring trisnorhopanes[9], designated Ts (18α(H), 21β(H)-22, 29, 30-trisnorneohopane) and Tm (17α(H), 21β(H)-22, 29, 30-trisnorhopane), also seem resistant to degradation These findings, together with previous studies of crude-oil biodegradation, imply that biodegradative alteration of hopanes can proceed through numerous pathways, which can result in widely differing distributions

We have analysed several tar-sand samples from the Miocene Pt Arena (Monterey) Formation in the Pt Arena Basin, California Tar-stained sandstones are distributed throughout siliceous organic mudstones exposed at several locations along the northern California coastline The thickest continuous tar-sand unit measures ~15 m, and consists of graded, medium-coarse-grained sands containing mudstone clasts at the base of some individual beds We collected the samples near this unit, either directly from the exposure or from eroded fragments lying nearby All samples seemed heavily weathered and varied in composition from a pliable tar distributed throughout a sand matrix to more bituminous, less viscous samples which would flow upon heating by sunlight We assume that most, if not all, biodegradation in these tar sands occurred following their exposure

Methylene chloride extracts of the tar sands consist of a sulphur-rich, bituminous material enriched in aromatic and polar components The composition of C_{15+} solvent-extractable material in four samples is shown in Table 1 Saturated hydrocarbons make up a small fraction of the extract (3 7–11 1%) and the asphaltene contents vary from 16 5 to 54 1% The sulphur content of the extractable material varies from 3 2 to 5 8% (Table 1) These characteristics are typical of high-sulphur petroleums, such as those in the Monterey Formation[10], that have been severely biodegraded Isotopically heavy ^{13}C compositions for the saturated and aromatic hydrocarbons (Table 1) indicate that the tar was most likely generated from facies equivalent to the Monterey Formation in the Pt Arena Basin[10 11]

The saturated hydrocarbons isolated from the four samples consist primarily of naphthenic compounds and are devoid of *n*-alkanes and isoprenoids, a composition characteristic of moderate to severe biodegradation[5,12] We confirmed the presence of tricyclic and pentacyclic triterpanes by gas chromatographic/mass spectrometric (GC/MS) analysis of the saturated-hydrocarbon fractions These results also revealed that 'normal' steranes (those with methyl groups substituted at the C_{10}- and C_{13} positions) have been completely biodegraded in all samples, and only diasteranes (C_5 and C_{14} methyl substituted) can be identified at low abundance in $m/z = 217$ mass chromatograms The 'normal' steranes are the most susceptible to degradation among tetra- and pentacyclic hydrocarbon biomarkers and their removal indicates that the extent of biodegradative weathering has progressed to at least level 7 on Volkman *et al*'s scale[4], which they describe as "very extensive" alteration

By contrast to the steranes, hopanes in these samples have been altered to varying degrees Figure 1 shows $m/z = 191$ mass chromatograms corresponding to the four samples in Table 1 The distribution in sample 87-2408 (Fig 1*a*), typical of Monterey-derived oils, exhibits several characteristic features such as the occurrence of 28, 30-bisnorhopanes (labelled 28H in Fig 1) and the C_{35} extended hopanes (labelled 35H, Fig 1) in higher abundance than the C_{34} homologues[13 14] These features have been variously related to source rocks deposited in either a sulphur-rich environment, in the case of the bisnorhopanes[14 15], or hypersaline environments, in the case of the C_{35} extended hopanes[16–18] We characterize the distribution in this sample as 'unaltered', although we are not certain how closely it resembles the pristine distribution before any biodegradation Comparison to triterpane distributions of undegraded Monterey-derived oils[13 14] suggests that the hopanes in this sample have not undergone significant alteration

Figure 1*b*, *c* show the effects of increasing biodegradation on

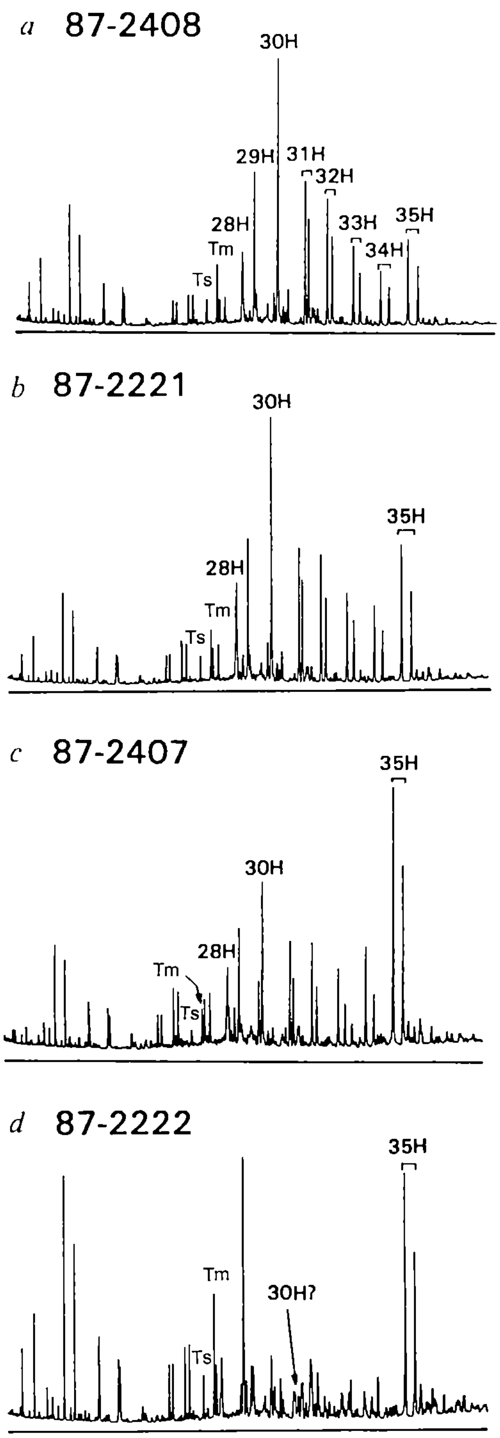

FIG 1 Mass chromatograms of $m/z = 191$ depicting triterpane distributions in Pt Arena tar-sand samples Homologous series of hopanes possessing 17α(H), 21β(H)-stereochemistry are denoted by their carbon number followed by the letter H The two commonly occurring trisnorhopanes are designated Ts and Tm Note the gradual loss of most hopanes relative to the C_{35} compounds with increasing degree of alteration (proceeding from *a* to *d*) In the most severely altered sample (Fig 1*d*) the principal triterpenoid compounds consist of tricyclic terpanes (not labelled), the trisnorhopanes Ts and Tm, the C_{35} hopanes, and various unidentified components Bisnorhopane was not detected in this sample Calculated concentrations of several hopanes (Table 1) indicate that the C_{35} compounds are being selectively preserved Chromatographic conditions 25-m fused-silica capillary column containing 5% phenyl methyl silicone (0 20-mm inner diameter, 0 33-μm film thickness) temperature programmed from 60 to 220° C at 25 °C min^{-1} and 220 to 325 °C at 2 °C min^{-1} after a 1 0-min isothermal hold, helium carrier gas (1 0 $cm^3 min^{-1}$), injector temperature 275 °C, mass spectrometric analysis carried out in SIM (selected ion monitoring) mode using a Hewlett-Packard 5970 Mass Selective Detector

‡ 28/30=28,30-bisnorhopanes/17α(H), 21β(H)-hopane, 35/30=C$_{35}$ extended hopanes (22*S*+22*R*)/17α(H), 21β(H)-hopane, %22*S*=C$_{31}$ extende hopanes (22*S*)/(22*S*+22*R*), T/T=17α(H)-trisnorneohopane/18α(H)-trisnorhopane

§ 28H, 30H, 35H=Concentrations of 28, 30-bisnorhopanes, 17α(H), 21β(H)-hopane and C$_{35}$ extended hopanes (22*S*+22*R*), respectively, expressed pe unit pentane-soluble extractable material Concentrations were calculated relative to an added internal standard (5α(H)-androstane) and are corrected fc differences in gas chromatograph/mass spectrometer response

the hopanes These include a preferential decrease in the abundance of 17α(H), 21β(H)-hopane (labelled 30H, Fig 1) relative to other hopanes and a slight decrease in the abundance of the 22*R* isomer of the C$_{33}$ and C$_{34}$ extended hopanes relative to the 22*S* isomer Most striking, however, is the increasing abundance of the 22*S* and 22*R* isomers of the C$_{35}$ hopanes relative to other hopanes This effect can be seen at its incipient stages in sample 87-2407 (Fig 1c) In the most severely altered sample (sample 87-2222), hopanes containing between 28 and 34 carbons have either disappeared or are present in exceedingly low abundance, and the C$_{35}$ compounds are prevalent (Fig 1*d*) The two most commonly occurring trisnorhopanes, designated Ts and Tm[9], also seem to remain relatively unaltered throughout the entire biodegradation sequence

The trends shown in Fig 1 are quantified in Table 1 The calculated bisnorhopane/hopane ratio shows an increase (from 0 55 to 0 94), suggesting that hopane is degraded slightly more rapidly during the incipient stages of biodegradation Similarly, the 22*S*% values (calculated from C$_{31}$ extended hopanes) increase very slightly with increasing extent of alteration, although we consider the value calculated for sample 87-2222 uncertain because of the difficulty in unambiguously identifying these compounds at the advanced stages of hopane alteration evident in this sample By comparison, the ratio of C$_{35}$/C$_{30}$ hopanes increases progressively from 0 90 to 14 49 with increasing extent of biodegradative alteration (Table 1) The Ts/Tm ratio changes little in the four samples

In the most degraded samples we can document the formation of 25-normethyl homologues Figure 2 shows mass chromatograms of $m/z=177$ and 191 for a severely altered sample, 87-947 The $m/z=177$ ion is diagnostic for triterpanes demethylated in the A/B ring system[4] Overall, the distribution depicted in the $m/z=177$ chromatogram is similar to the 'unaltered' hopane distribution (Fig 1*a*), but differs in several respects We attribute some of these differences to the fact that the response at $m/z=177$ for 25-normethyl hopanes is not the same as that for the corresponding hopane at $m/z=191$ Thus the greater abundance of the demethylated C$_{28}$ compound in the $m/z=177$ chromatogram relative to the C$_{29}$ hopane in the $m/z=191$ chromatogram is due to differences in the mass spectra of the respective compounds Two characteristics of the respective distributions, however, are truly different First, the demethylated C$_{34}$ homologues of the C$_{35}$ hopanes occur at much lower abundance than in the 'unaltered' hopane distribution Second, the demethylated C$_{26}$ homologues of the trisnorhopanes Ts and Tm are absent The latter result differs from studies of biodegraded Australian oils, in which demethylation of these compounds with a distribution similar to that of the hopanes was observed[4] Both observations indicate selective preservation of these compounds in severely altered samples after most other hopanes have been degraded (such as in Fig 1*d*) These feature are illustrated in Fig 2

Several explanations can be invoked to account for the preservation of the C$_{35}$ extended hopanes The carbon skeleton o these compounds very closely resembles that of the bacteriohopanetetrol precursor Because bacteria mediate th degradation process, it might be suggested that these compound were added to the bituminous material in the tar sands durin the biodegradation process through the incorporation of microbial remains We can dismiss this argument for several reasons Absolute biomarker concentrations, calculated relative to a added internal standard, indicate that the concentration of th C$_{35}$ compounds is relatively invariant from the least to the mos severely degraded sample Whereas concentrations of bisnorhopane and hopane shown in Table 1 decrease with increasin degree of alteration, concentrations of C$_{35}$ extended hopane remain relatively constant at 369-461 p p m The lowest C$_{35}$-hopane concentration is associated with the one sample having a significantly higher asphaltene content (Table 1), which migh account for the slightly diminished value This constancy would

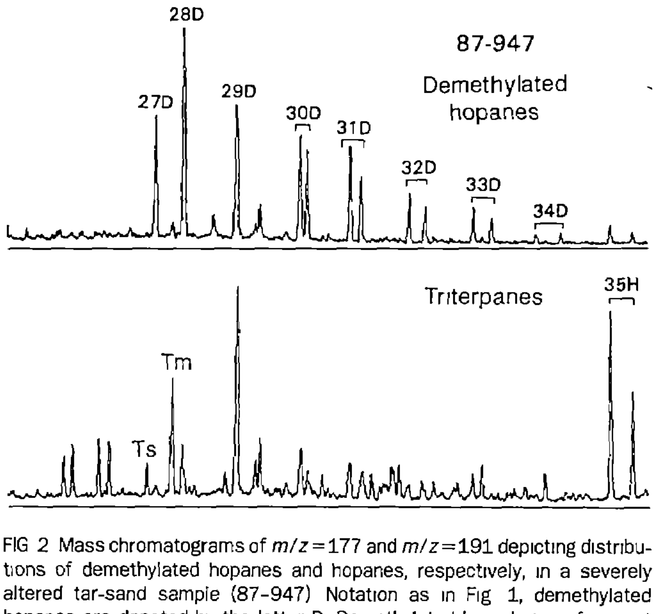

FIG 2 Mass chromatograms of $m/z=177$ and $m/z=191$ depicting distributions of demethylated hopanes and hopanes, respectively, in a severely altered tar-sand sample (87-947) Notation as in Fig 1, demethylated hopanes are denoted by the letter D Demethylated homologues for most hopanes shown in Fig 1*a* are present in the $m/z=177$ chromatogram with the exception of the trisnorhopanes Ts and Tm and the C$_{35}$ hopanes These compounds are the only hopanes recognized in the $m/z=191$ chromatogram Chromatographic conditions as in Fig 1, mass spectrometric analysis conducted using a Finnigan 8222 magnetic/electric-sector instrument (1 000 resolution)

be more characteristic of selective preservation, as it would be very unusual for these compounds to be added at the same rate as they are removed, and also rules out mechanisms involving progressive degradation of the C_{35} compounds at a greatly diminished rate relative to the other hopanes. Further, it would be highly unusual for these compounds to come from a biological source in the geologically preferred distribution, nearly completely isomerized at the C_{22} position (Fig. 1*d*).

The most plausible explanation for these observations is that, under the surface weathering conditions to which these tar sands have been exposed, the C_{35} extended hopanes are resistant to biodegradation. The same conclusion would seem to apply for the trisnorhopanes Ts and Tm. To the best of our knowledge, this hopane biodegradation sequence has not been reported previously. It is therefore difficult to assess the extent of its occurrence in the alteration of triterpanes in biodegraded oils. Enhanced C_{35}-hopane abundances are characteristic of specific environments of deposition, hence these observations may only apply to biodegradation of oils generated from source rocks such as carbonates, hypersaline sources or Monterey Formation analogues. Our observations are, however, somewhat serendipitous because they came about as a result of analysis of various tar-sand samples from the same location. Similar degradation sequences might go undetected unless several samples of the same oil that were biodegraded to varying extents were analysed.

These findings, together with previous studies of crude-oil biodegradation, imply that biodegradative alteration of hopanes can proceed through numerous pathways, which can result in widely differing distributions. Collectively, these pathways are probably more complex than the generalized degradation sequences described by either Volkman *et al.*[4] or Connan[5]. The environmental conditions under which biodegradation takes place (such as the temperature, oxygen level or salinity associated with in-reservoir conditions) may govern the composition of microbial communities active in biodegradative processes[7], which in turn dictate the specific molecular transformations that are observed. This has been substantiated by results of various laboratory simulation studies[8,19]. Caution must be used when evaluating source-rock deposition environments from analyses of hopane distributions in oils[16,18], particularly if the assessments involve analysis of petroleum seepage[20], as the alteration effects associated with biodegradation can be severe. ☐

Bacterial mats from Crater Lake, Oregon and their relationship to possible deep-lake hydrothermal venting

Jack Dymond, Robert W. Collier* & Mary E. Watwood†

* College of Oceanography, Oregon State University, Corvallis,
Oregon 97331, USA

New Mexico 87131, USA

CRATER Lake is located in a caldera on Mt Mazama, a volcanic centre in the Oregon Cascades which has been active for more than 400,000 years[1]. The 594-m-deep lake is a consequence of a climactic eruption which occurred 6,845 ± 50 years ago; however, caldera volcanism took place as recently as 4,000 years ago[1]. It has been suggested that some of the physical and chemical features of the lake result from hydrothermal inputs[2–7]. Here we present submersible observations of the bottom of Crater Lake, which reveal communities of bacteria that are usually associated with anomalously warm, saline waters. The bacteria seem to derive energy from the oxidation of ferrous iron to fuel their metabolism. We propose that the mats are indicators of diffuse hydrothermal venting into the deep lake.

During August of 1988, 16 dives in the one-person submersible *Deep Rover* were carried out in the lake. Nine dives were in the south-central part of the lake, an area of high heat flow[4] and anomalous compositions and temperatures of the bottom water[7]. We observed bacterial mats at six locations in this area; at some sites multiple mats were present. All mats observed were within 300 m of each other and were either on or near an escarpment with a north-east/south-west orientation. The mats are gelatinous, low-density, 15–300 cm in diameter and 2–15 cm thick. Some of the largest ones are draped over steep rock outcrops (Fig. 1), and the smaller mats lie directly on sediments. Sediments near the mats are dark and contrast sharply with the normal buff-coloured sediments. The maximum water temperature anomaly in the immediate vicinity of the mats was 0.1 °C. Insertion of a temperature probe into the mat, however, revealed temperatures ranging from 4.70 to 9.52 °C, up to 6.0 ° above the typical 3.5 °C bottom water. In addition to the

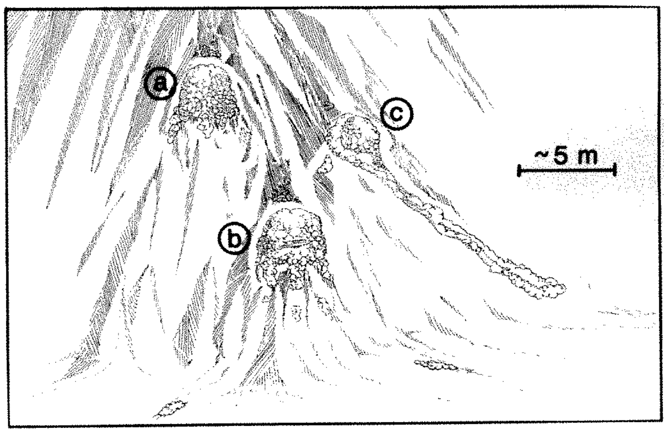

FIG. 1 A schematic drawing of bacterial mats observed during dive 179. The three principal mats observed at this site are identified by 'a', 'b', 'c'. These large mats seem to be attached to rocky cliff faces. Mat 'c' extends down the cliff face a further 10 m below the primary structure. This extension seems to be actively growing and not simply a consequence of pieces that roll down the slope. Small mats are growing at the base of the slope on sediments. The sediments along the base of the slope are discoloured, apparently because of Fe and Mn precipitation. Mat sample and mat waters shown in Tables 1 and 2 were recovered from 'a'.

TABLE 1 The composition of the bacterial mat and other iron-rich deposits

	Bacterial mat	Galapagos mounds[26]	Santorini[27]	Drive 187 crust*
Al	0.21	0.32	0.87	0.46
Si	7.2	13.3	6.8	11.7

C	2.44	—	4.0	—
N	0.97	—	—	—

All values are in weight per cent as determined by complete dissolution with HF/HNO_3 acids and analysis by atomic absorption spectrophotometry. The dashes indicate that no measurements were made.

* A lithified crust recovered from a sedimented bottom in the general region of the bacterial mats.

temperature anomalies associated with the mats, waters with anomalous concentrations of ^3He, Mn, ^{222}Rn, Li, Si and Cl have been observed at and near these features[8-10].

A predominantly bacterial composition for the mats (genera *Gallionella* and *Leptothrix*) is confirmed by scanning electron microscopy (Fig. 2). The sheath-forming *Gallionella* is generally considered to be a chemolithoautotroph[11] as it requires a source of reduced iron[12] and will grow in the absence of significant organic carbon[13]. It is not necessarily thermophilic because it has been found in low-temperature springs, wells and drainages[12], but this genus has been observed in thermal springs with temperatures up to 47 °C (ref. 14). Because of the accumulations of ferric hydroxide and manganese dioxide accumulations on the sheaths of *Leptothrix*, these bacteria are thought to oxidize ferrous and manganous ions[15]. An autotrophic metabolism for *Leptothrix* has not been demonstrated, but, like *Gallionella*, it seems to thrive in environments that provide a gradient between reduced and oxidized forms of iron and manganese. *Leptothrix* is also not a thermophilic form, but it has been observed in the recently discovered thermal springs on Loihi Seamount, the most eastward extension of Hawaiian-chain volcanism[16]. There thick mats similar to the Crater Lake communities surround vents with temperatures that range between 15 and 30 °C (ref. 17).

In Table 1, the bulk composition of a bacterial mat is compared with that of hydrothermal iron oxide precipitates from several marine hydrothermal deposits and some iron-rich crusts collected in the vicinity of the Crater Lake bacterial mats. The mat contains >35% iron, which accounts for >70% of the mass of the mat (as FeOOH). Significant amounts of silica and phosphorus are also present. The relatively low sulphur content indicates that sulphur-oxidizing bacteria, which would transform hydrogen sulphide into elemental sulphur or sulphate, are not important members of the bacterial community. The concentrations of iron, aluminium and silicon in the mats and the hydrothermal oxide deposits are similar. The composition of the lithified crust is very similar to that of the bacterial mat.

Although the scanning electron micrographs demonstrate that the bacterial mats are predominantly composed of sheath-forming bacteria, only 2.4% of the material is organic carbon. It is probable that most of the bacteria shown in Fig. 2 are remnant sheaths rather than viable bacteria. Analyses of the organic fraction demonstrate that the extractable lipids are simple fatty acids. Sterols and other indicators of phytoplankton, zooplankton or local terrigenous sources are absent. In addition, the atomic ratio of carbon to nitrogen in the mat (2.9) is low compared with organic matter from plankton and is similar to bacterial sources of organic matter[18]. These analyses are consistent with fresh organic matter of microbial origin.

Within the general area where bacterial mats were found, we also observed lithified crusts of iron- and manganese-enriched material similar to the crust reported in Table 1. At some locations these deposits formed continuous pavements several metres across. At other sites multicoloured, pebble-sized material overlay what seemed to be normal sediments. The pebbles seem to be fragments of the lithified crusts.

Water associated with a bacterial mat was sampled by placing the open end of a cylindrical water sampler directly within the

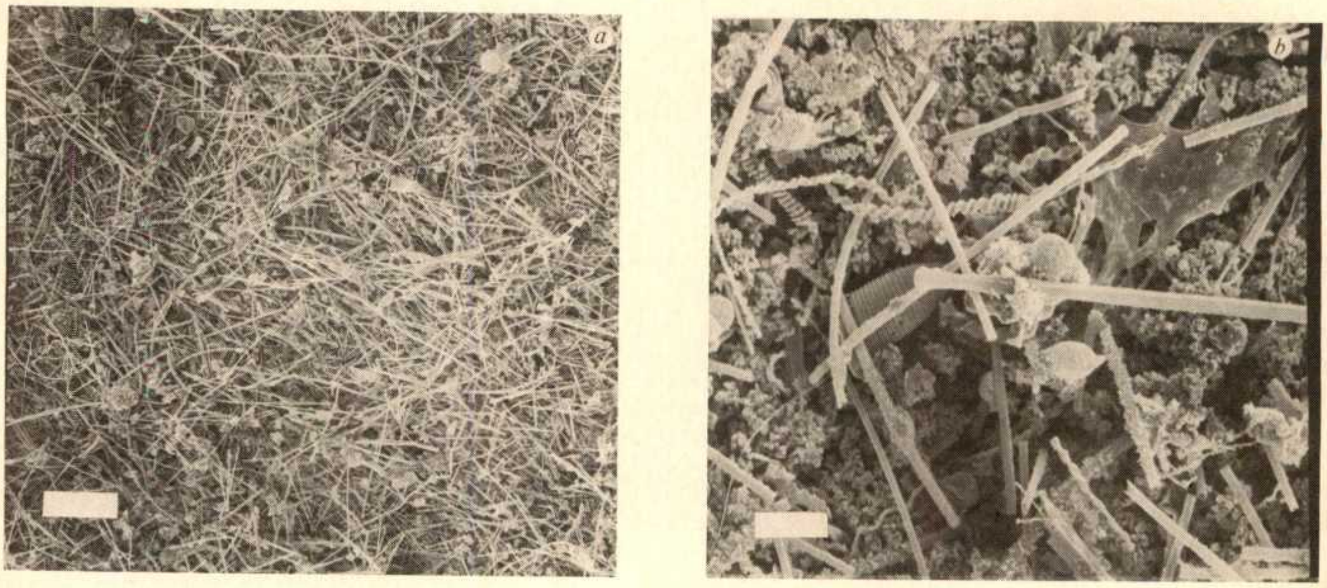

FIG. 2 *a*, A low-power scanning electron micrograph of the bacterial mat from dive 179. Tentative identification indicates these forms are iron-oxidizing sheath-forming bacteria of the genera, *Gallionella* and *Leptothrix*. The scale bar is 100 μm in length. *b*, A scanning electron micrograph of the bacterial mat from dive 179. The scale bar is 10 μm in length. The genus, *Gallionella* are the forms with twisted sheaths; *Leptothrix* are the straight sheaths. The ribbed dome-like form in the centre is thought to be a protozoa. This form is seen on many of the scanning electron micrographs and could be feeding on the bacteria. The tube-like form in the centre-right with a blunt end is part of a diatom.

TABLE 2 Chemical composition of bacterial mat water and normal deep lake water

Sample	Na ($\mathrm{mg\,l^{-1}}$)	K ($\mathrm{mg\,l^{-1}}$)	Ca ($\mathrm{mg\,l^{-1}}$)	SO_4 ($\mathrm{mg\,l^{-1}}$)	Cl ($\mathrm{mg\,l^{-1}}$)	SiO_2 ($\mathrm{mg\,l^{-1}}$)	Li ($\mathrm{\mu g\,l^{-1}}$)	Mn (nM)
7.3 (hydrocast, 1987, 351 m)	10.4	1.71	6.73	10.2	10.6	17.3	44.1	0.6

All analyses are by atomic absorption spectrophotometry.

mat (~10% of the sampler body penetrated the mat). After closing, the sampler retained several centimetres of mat material and a water sample that represents a mixture of the 'mat water' and of the local bottom water around the mat.

The bacterial-mat water sample contains the highest concentration of dissolved ions of any water sample collected within the caldera (Table 2). The concentrations of the major ions are approximately double the lake-water values, and the Mn concentrations are one thousand times higher than deep lake water. The mat water is an appropriate chemical 'endmember' that could explain the anomalously high concentrations of ions in Crater Lake[10]. Because of the sampling method, the extent of dilution of the bacterial-mat fluids by normal lake water is uncertain. A conservative estimate, based on relative volumes alone, suggests a 1:10 dilution of mat water by lake water. Thus, *in situ* mat-water concentrations are probably an order of magnitude larger than those shown in Table 2.

Elevated temperatures of fluids within the mat indicate geothermal heating. The contribution of heat by bacterial metabolic activity can be shown to be insignificant. (Assuming that the heat produced by oxidation of all dissolved ferrous ions in mat fluids is retained within the mat an upper limit to the metabolic heat production can be calculated. Using this closed-system assumption, the increase in temperature is a function of the concentration of iron in the fluids. An appropriate reaction is:

$$Fe^{2+} + \tfrac{3}{2}H_2O + \tfrac{1}{4}O_2 \rightleftharpoons FeOOH(s) + 2H^+$$

The enthalpy of this reaction[19] is $-9.2\ \mathrm{kcal\,mol^{-1}}$. Assuming an upper limit of 1.0 mM iron[20], conversion of all the dissolved iron to solid form would add ~9 cal of heat to each litre of water. Thus, the reaction would raise the temperature of that water by less than 0.01°.) Chemical geothermometers[21,22] permit an estimate of the water–rock reaction temperature of mat fluids. Assuming the mat-water sample (Table 2) was diluted ten times with normal lake water, the original concentration would be: $Na = 99\ \mathrm{mg\,l^{-1}}$; $Ca = 65\ \mathrm{mg\,l^{-1}}$; $Mg = 37\ \mathrm{mg\,l^{-1}}$; $K = 15\ \mathrm{mg\,l^{-1}}$; $SiO_2 = 128\ \mathrm{mg\,l^{-1}}$. If chalcedony (a microcrystalline form of quartz) is the phase controlling the silica content of the fluids, we estimate a temperature of 81 °C for the rock equilibration temperature of the mat fluid. Using the Na-K-Ca geothermometer[21,22] (with no Mg correction) a temperature of 86 °C is calculated. There may be significant errors in the estimated temperatures because the assumed solubility and exchange reactions are slow to reach equilibrium at these relatively low temperatures and our endmember fluid composition is not well constrained. The result, however, is consistent with a geothermal source of the mat waters, and ~80 °C is our best estimate for the rock equilibration temperature of the geothermal fluids.

We conclude that the mats are produced by bacterial communities that oxidize ferrous iron carried in the fluids advecting through the mat. We base our assertion of fluid advection on the thermal and chemical gradients across the mats and the likelihood that the abundant growth of organisms requires a steady supply of reduced iron. We did not, however, measure or see evidence of flow through the mat, but dispersed and subtle flow of fluids would not be observable in the presence of the physical disturbance around the submarine.

We hypothesize that bacterial mats, lithified crusts and pebbled surfaces represent sequential stages in the evolution of precipitates that form from heated fluids that advect through sediments and rocky outcrops at certain locations on the lake floor. The elevated temperatures and enrichment of these waters in elements commonly associated with thermal waters such as silicon, chlorine and lithium (Table 2) indicates the fluids are the result of hydrothermal circulation. Moreover, ^3He, a definitive tracer of a mantle source, is strongly enriched in lake bottom waters near the bacterial mat[9], compatible with hydrothermal input.

The following scenario can account for the presence of mats and crusts: iron-oxidizing, chemolithotropic bacteria precipitate large amounts of iron in mats at interfaces between the anoxic advecting fluids and oxic lake waters. Because these organisms require a source of ferrous iron, they thrive only as long as the advection of fluids continues. If the thermal-fluid advection is through sediments, as opposed to rock, excess pore pressure and doming of the sediments will result, similar to that observed in sediment-hosted hydrothermal systems in the oceans[23-25]. Precipitation within the conduits of hydrothermal systems, however, eventually blocks the flow and venting stops at a given site. When this occurs, the bacterial mat is transformed from a gelatinous living structure to a lithified crust. Cessation of venting would result in dome collapse and breaking of the lithified crusts would account for the pebble fields of mixed crust varieties. □

The earliest known reptile

T. R. Smithson

Cambridge Regional College, Newmarket Road, Cambridge CB5 8EG, UK

AMNIOTES (reptiles, birds and mammals) are distinguished from non-amniote tetrapods (amphibians) by the presence of complex embryonic membranes. One of these, the amnion, gives its name to the group. Very few skeletal characters distinguish amniotes from amphibians[1], making it difficult to recognize early amniotes in the fossil record. The earliest amniote fossil identified so far is *Hylonomus* from the Westphalian (Upper Carboniferous) of Joggins, Nova Scotia[2,3], (~300 Myr). I report here the discovery of a much earlier amniote skeleton from the Brigantian (Lower Carboniferous) of Scotland (~338 Myr)[4], which thus represents the earliest occurrence of amniotes in the fossil record. The specimen was collected from the East Kirkton Limestone, near Bathgate, West Lothian[4-8], and is part of a unique terrestrial fauna that includes eurypterids, myriapods, scorpions and the earliest-known harvestman spider[7,9], together with the earliest known temnospondyls, a group that may include the ancestors of all living amphibians[10]. It will make an important contribution to our knowledge of early amniote morphology and the interrelationships of tetrapods.

The specimen described here (SPW2326) currently forms part of the private collection of Stanley Wood who found it in the black shale member of the East Kirkton succession. It is preserved in part and counterpart and consists of an almost entire articulated skeleton (Fig. 1) which has been split into halves so that little surface detail of the bones is visible. The bedding plane in which the specimen lay is slightly contorted, disrupting the anterior parts of the skeleton. The total length of the skeleton is between 180-200 mm (presacral length ~120 mm).

The skull has been crushed dorsoventrally. Most of the skull roof is preserved, together with the right cheek and mandible which have been displaced laterally (Fig. 2*a*). Little of the palate is visible, but there is evidence that it is concealed beneath the overlying bones of the skull roof. The snout-occiput length is ~18 mm and the snout-quadrate length ~20 mm. The preorbital region shows a pattern of bones common to all early tetrapods, with midline frontals and nasals flanked laterally by pre- and postfrontals and large premaxillae anteriorly. But, unlike other Carboniferous amniotes such as protorothyridids[11] the pre- and postfrontals are in contact, preventing the exposure of the frontal in the orbital margin (Fig. 2*a*). In the post-orbita region the midline parietals appear to contact the postorbita and squamosal. There is no evidence that the temporal series (intertemporal, supratemporal and tabular) intervenes between the parietals and cheek bones. The squamosal, postorbital, juga and quadratojugal are arranged in the primitive tetrapod pattern[12]. Nine sclerotic plates are preserved in the dorsal half o the orbit.

The vertebral column is preserved in articulation, although in places the bone is eroded, making it difficult to distinguish individual bones. There are approximately 32 presacral vertebrae and a similar number make up the preserved portion o the tail. The first eight presacral vertebrae are preserved in dorsa view, the remainder in lateral aspect. The form of the vertebrae is illustrated in Fig. 2*b*. The hourglass-shaped centrum seems to be fused to the neural arch which bears a short neural spine Between each successive centrum is a wedge-shaped intercentrum. This is relatively much larger than those of the Westphalian protorothyridids[2], but much smaller than those of other reptiliomorphs from East Kirkton[6,7]. The neural arches are narrow and unswollen, and all the presacral vertebrae seem to bear ribs.

The pectoral girdle and fore limbs are incompletely preserved, and will require detailed study before they can be adequately described, but the pelvic girdle and hind limbs are very well preserved. They lie below the vertebral column except that the left pes overlies vertebrae in the sacral region, obscuring detail of the pattern of its bones. The right pelvis and hind limbs are illustrated in Fig. 2*c*. The camera lucida drawing was made of the bones as preserved on the counterpart block and thus appears to be from the left side of the skeleton. The dorsoventrally flattened pelvis consists of a large puboischiadic plate 16 mm long and a relatively short, narrow iliac blade ~6 mm long. The limb bones are long and gracile. The femur is 11 mm long and the tibia and fibula are each ~6 mm long. The right pes is very well ossified and the majority of bones are preserved. Two large proximal tarsal bones are readily identified and are almost certainly the homologues of the astragalus and calcaneum of extant amniotes. Most of the centralia are preserved in close apposition to the metatarsals, but the distal bones of the foot have folded back towards the epipodials. The digits are very

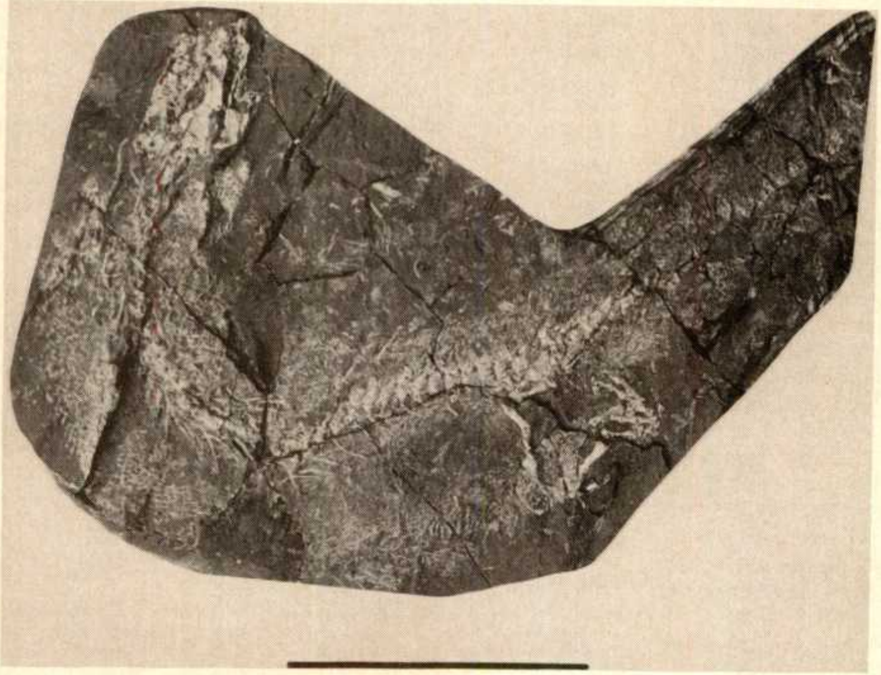

FIG. 1 Fossil amniote skeleton from the East Kirkton Limestone (SPW2326). Counterpart block. Scale bar, 50 mm.

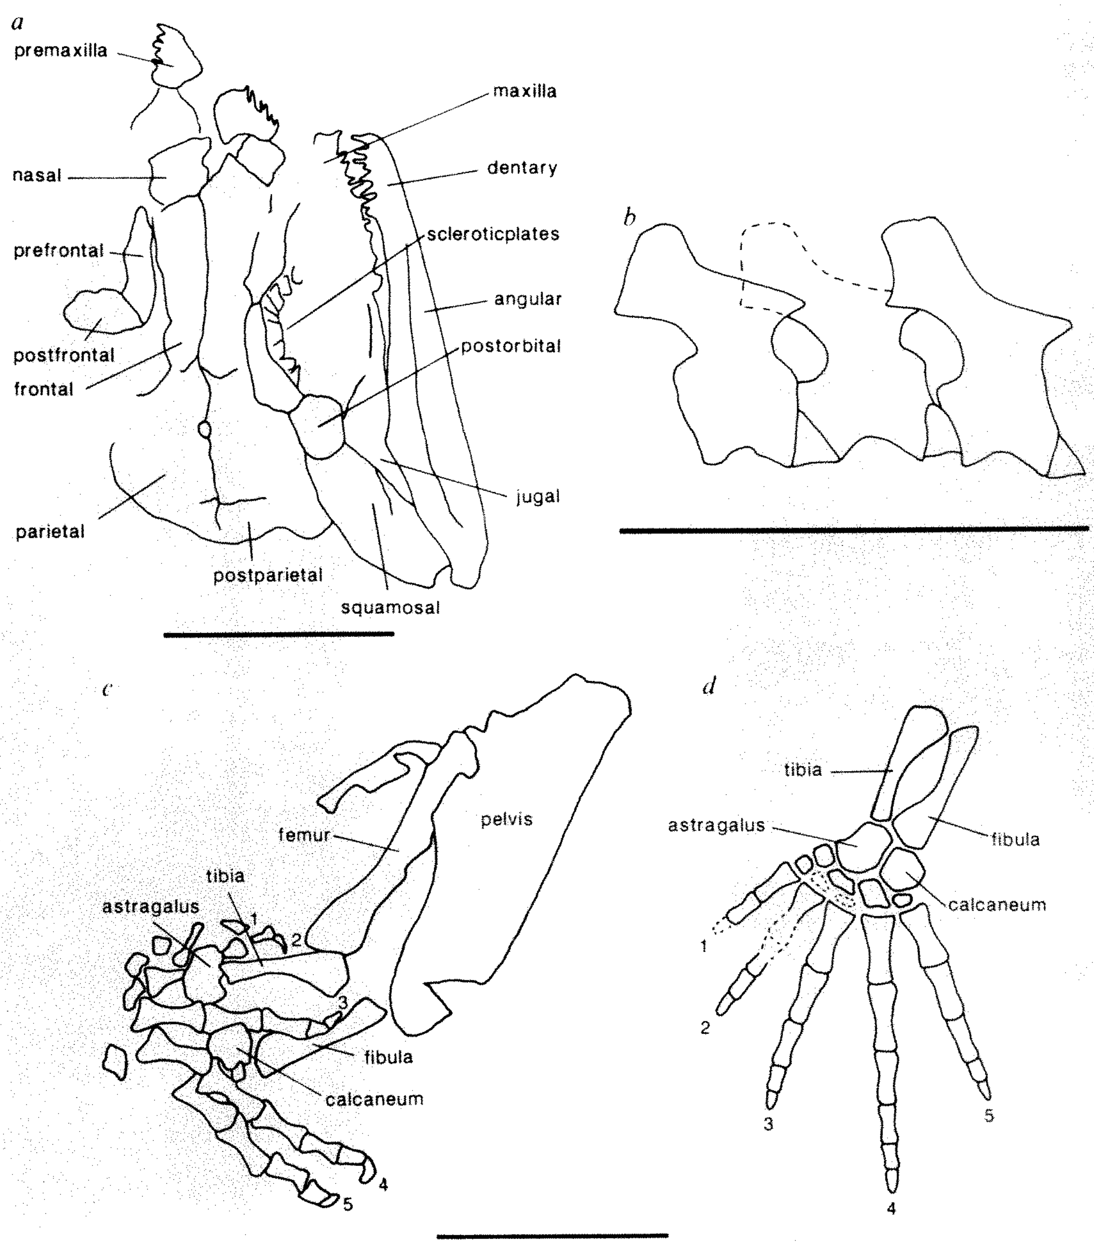

FIG. 2 Fossil amniote (SPW2326). *a*, Skull, dorsal view. Composite figure based on data from part and counterpart halves. *b*, Trunk vertebrae (approximate presacral numbers 20–22), lateral view. *c*, Right pelvis and hind limb drawn from counterpart block. *d*, Restoration of right tibia, fibula and pes, reversed. Scale bars, 10 mm.

well-articulated and the pattern of phalanges is clear in all but the first digit, in which the terminal phalanx appears to be missing. The phalangeal formula is 23454. A restoration of the tibia, fibula and pes is shown in Fig. 2*d*.

SPW2326 is placed in the Amniota on the basis of the presence of an astragalus and calcaneum (a character it shares with extant amniotes) and the reduction of the temporal series to permit contact between the parietal, the postorbital and the squamosal (a character shared with other Carboniferous amniotes). Among Palaeozoic tetrapods, the presence of an astragalus and calcaneum is not a unique feature of amniotes: these bones have been described in a number of microsaurs[13]. But the microsaur skull is characterized by a single large bone in the temporal series, usually described as the tabular, which separates the midline parietal from the postorbital and squamosal bones of the cheek. In addition, no microsaur has been described with a pedal phalangeal formula 23454, although this pattern has been restored in *Tuditanus*[14]. No other features are evident on SPW2326 that would indicate relationship with other groups of Carboniferous amphibians. The pattern of the skull roofing bones of SPW2326 precludes relationship with one of the groups of non-amniote reptiliomorphs (see ref. 1) or with the taxon including ichthyostegids, colosteids and temnospondyls. It lacks the unique vertebral morphology of nectrideans[15] and the aberrent cranial morphology of lysorophids and adelogyrinids[13], whereas the presence of limbs excludes it from the Aïstopoda.

SPW2326 is thus considered to be an amniote. However, its position within the Amniota remains to be determined and must await detailed description. The absence of lateral temporal openings in the skull clearly precludes inclusion in the Synapsida or Diapsida, but its relationships with the other two major groups of Carboniferous amniotes, the Captorhinidae and Protorothyrididae[11] are unclear. It remains to be seen whether the discovery of SPW2326 will help to resolve the problem of the relationship of amniotes to non-amniotes. Recent discussion of this problem has been dominated by an analysis of characters from the braincase and otic region of Upper Carboniferous and Lower Permian taxa[1,16,17]. But, as the whole skeleton of the earliest amniote becomes better known, and the other reptiliomorphs from East Kirkton are described, it is anticipated that new characters will be discovered which will provide tests for current phylogenetic hypotheses. ☐

ACKNOWLEDGEMENTS. I am grateful to Mr Stanley Wood for the invitation to write this preliminary description of his new specimen and Dr Ian Rolfe for providing facilities at the Royal Museum of Scotland during its study. I thank Drs Robert Carroll, Andrew Milner, Alec Panchen and Mr Wood for helpful criticism of earlier drafts of the manuscript.

Evidence from aphasia for the role of proper names as pure referring expressions

Carlo Semenza & Marina Zettin*

Dipartimento di Psicologia Generale, Piazza Capitaniato,
3, 35139 Padova, Italy

HERE we describe a patient who, as a result of brain damage, had a dramatic inability to retrieve proper names, and who thus offered the opportunity of observing the distinction made in the brain between proper and common names. Although category specific aphasic disturbances are relatively common[1,2], this patient's anomia for proper names is very rare: only two other cases have been described so far[3,4]. The opposite phenomenon, a selective sparing of proper names, has also been recently observed[5]. It is widely assumed that double dissociations such as this reflect the premorbid organization of the cognitive system: the categories of proper and common nouns, therefore, would be separately represented or, at least, separately accessed in the intact brain. The only other such deficits, including the inability to learn arbitrary links between words and to guess the titles of pieces of music, are believed to be indicative of a problem in dealing with purely referential relations. This, in turn, would indirectly confirm the role of proper names as pure referring expressions.

L.S. was a 41-year-old employee in a hardware store, with eight years of education, who suffered a head trauma after a riding accident in July 1988. At that time a computerized tomography documented a left fronto-temporal lesion; in September 1989 NMR scanning showed a similar picture, emphasizing the involvement of basal structures. Clinical examination revealed no neurological signs, and no psychiatric pathological signs were ever observed. Very mild word-finding difficulties were noted. In September 1988 no pathological signs were detectable in his spontaneous speech or in his language comprehension. His residual deficit consisted almost exclusively of a dramatic inability to retrieve proper names either spontaneously or on formal testing. This deficit affected only oral and written word retrieval, because his auditory and written comprehension of proper names were both intact. On neuropsychological examination with standard test batteries[6,7] he obtained normal scores: in particular his visual recognition (including faces), spatial imagery, short- and long-term memory (with the exceptions reported below) were found to be intact. He accomplished perfectly all standard linguistic tasks. The following is a description of his inability to retrieve proper names and of his associated disorders.

In visual-confrontation naming he was 100% correct with real objects (50 items) and he scored 98 out of 100 with pictorial material. Categories shown in previous studies to be often selectively sensitive to brain damage[1] were also separately tested in a confrontation naming paradigm. A minimum of ten items for each of these categories were used as stimuli: L.S. made no errors. His performance with proper names was completely different. With real persons his knowledge of names was limited to those of most members of his family, which he had relearned during the months before testing. He gave correct information, however, about other real persons ("doctor"), and never experienced recognition problems. When presented with pictures of famous persons his naming performance was 2/25. Nonetheless, he provided correct information and details about these people's identities in every case (for example "prime minister"). In all cases he had no problems in matching spoken-aloud or written names with the pictures in a multiple-choice test. This ability to retrieve geographical names was tested using a blank atlas and pictures of the sites of well-known cities. He could name only 6/15 pictures and 4/15 map sites, but he was able to match them correctly in pairs. He also gave correct information about all of the items. In addition he was tested using the blank atlas on rivers (naming 3/8), countries (2/8) and mountains (2/8). Again, for all items, he provided a vast amount of correct information. We confronted him with several popular pieces of wordless classical music. If he demonstrated that he recognized them by singing along and continuing the melody appropriately when the music stopped, then we asked him to name the piece. He was unable to retrieve the title of any of such 12 pieces, regardless of whether their proper names were very abstract ('5th Symphony') or descriptive ('Moonlight Sonata'). He was also unable to provide the names of the composers.

In naming from definition L.S.'s performance was again very satisfactory provided that proper names were not the target. His score was 75/80, the stimuli being various categories of nouns (including animate beings, inanimate objects and abstract nouns), adjectives, verbs and numbers. By contrast, his performance with proper names was very poor; he scored 5/8 for relatives, 2/15 for famous persons, 3/5 for cities, 1/5 for mountains and 3/5 for countries. He could point correctly to all the geographical locations on the blank atlas. Phonological cueing (consisting of the first phoneme of the name) alone never improved his performance in generating proper names on either confrontation or definition. Semantic cueing was more effective, but only in the particular case in which the proper name also had a real meaning. For instance, Colombo (Columbus) in Italian means 'pigeon': L.S. seemed to be helped if the description included a cue to the meaning of the name ("Tell me who discovered America. He had the name of a bird.") His performance was correct in 4 out of 15 items of this kind, and when helped also with a phonetic cue he was able to score 9/15.

Naming by category in one minute was also tested. In this case he provided the names of 12 fruits, 11 vegetables, 9 birds, 13 clothes, 6 forms of footwear, 16 body parts, 15 means of transportation, 13 occupations, 12 sports, 7 carpenter's tools, 10 types of pasta, 13 common names beginning with the letter 'F', 9 beginning with 'M' and 10 beginning with 'S'. In the same time limit he was able to generate 12 proper names when "any person's name" was requested, but his performance dropped dramatically when more delimited categories were asked (one musician, two sportsmen, two actors, and two politicians). Additional time did not improve his performance with proper name categories, whereas for all other categories he continued to give new correct items.

L.S. was able to repeat immediately any proper name and to retrieve it if allowed to rehearse it silently without interference. Any interference procedure (such as counting backwards), however, caused his performance to drop to zero in 15 seconds.

---

* Present address: Clinica Ausiliatrice, Via Peyron, Torino, Italy.

The ability to acquire arbitrary associations between pairs of words, which may be considered as conceptually equivalent to naming proper names, was finally tested. The patient was given the paired-associate learning task from the Wechsler Memory Scale and the Bisiach, Cappa and Vallar[7] battery. He quickly learned the 'easy' pairs (in which the two words have a semantic relation to each other, such as 'north'-'south'), but he showed a chance performance over several attempts in retrieving the second member of the pair, given the first, when the relation between the two was totally arbitrary (such as 'clock'-'pear'). By contrast, he had no difficulty in a word-learning task. Specifically his score on a ten-word free-recall task (three trials) was within the normal range[7]. At work he also had great difficulty in learning numerical labels consistently when applied to certain items of hardware.

Our evidence indicates a common denominator underlying L.S.'s performances: the inability to deal (at the retrieval level) with purely referential nondescriptive semantic relations. Indeed, proper names are believed by some philosophers of language[8,9] to be pure referring expressions. According to Frege's[10] distinction, proper names just carry 'reference', that is they denote the individuals or the entities that are called by them, but have no 'sense', that is, they do not describe any property or imply any attribute. They are the opposite of 'descriptions', which have sense and which encompass all common nouns. Meaningless labels, which is what pure referring expressions are, could indeed need an independent system to take care of them; in L.S. this system would be disrupted. Psychologically, this makes more sense than the alternative explanation that L.S.'s inabilities arose because of a difficulty purely in retrieving proper names; in this case one would be left with the problem of specifying what particular quality makes it useful for the brain to implement proper names independently from common ones. The need of an independent system may still be there even if proper names were not meaningless labels but 'shorthand descriptions', as some authors[11] prefer to the pure reference theory. A descriptive value, varying from none (or very little) to presumably a lot, would be in any case an important dimension in the organization of semantic memory. It would be orthogonal with other dimensions such as the one defined by the prevalence of structural or functional attributes, which also has been suggested to determine category effects in aphasia[12].

There are at present only a few highly speculative models of the actual wiring in the nervous system of such organization: those involving modularly distinct subsystems[12,13] or regions of relative specialization within a distributed net[2,5] are the more accredited ones.

Note added in proof. Note also that a substantially similar argument comes from modern linguistics. In Jackendoff's theory of natural language semantics, an important distinction in conceptual structure is the binary feature Type/Token[14]. What one learns and stores in memory can be linked either with Token (if one is remembering an individual) or with Type (if one has learned a category). Proper names appear typically to denote individuals. ☐

Analysis of fusion gene and encoded photopigment of colour-blind humans

Jay Neitz, Maureen Neitz & Gerald H. Jacobs

Department of Psychology and Neuroscience Research Institute,
University of California, Santa Barbara, California 93106, USA

IN humans, long-wavelength-sensitive and middle-wavelength-sensitive cone pigments are encoded by genes lying in a head-to-tail tandem array on the X chromosome. Deficiencies in red-green colour vision seem to arise from unequal recombination of these normal X-linked genes[1,2]. In some dichromats this recombination is believed to yield a fusion gene encoding a product with an absorption spectrum similar to that of one or the other of the normal photopigments[2]. Until now, however, such a relationship between the structure of a pigment gene and the spectral properties of its encoded pigment has not been directly shown. We have now sequenced a fusion gene isolated from a red-green colour-blind human and determined the spectral properties of the pigment that it encodes. The absorption spectrum of the photopigment was very similar to that of normal middle-wavelength-sensitive photopigment, even though about half of its DNA coding sequence seems to be derived from a gene encoding normal long-wavelength-sensitive pigment. These results indicate the regions of the X-encoded photopigment apoproteins that are responsible for differences in their spectral tuning, and imply that the striking variations in colour vision among anomalous trichromats of a particular type are not attributable to anomalous pigments with differing spectral peaks.

We established the colour vision of a 31-year-old male by psychophysical tests in which the appearances of mixtures of red and green primary lights were compared with the appearance of a standard yellow light (the Rayleigh match). He accepted

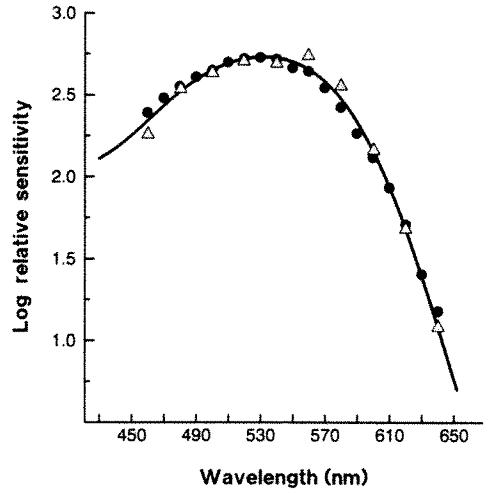

FIG. 1 Comparison of the spectral sensitivity of the MWS cone pigment from a protanope with the MWS cone pigment from a colour-normal human. ●, Protanope ERG sensitivity values corrected for pre-retinal absorption by the lens[12]. △, Spectral sensitivity of MWS cone pigment from a normal trichromat[6]. The wavelength of peak sensitivity for each was determined by translating a standard visual pigment absorption curve[13] on a log-wavenumber axis to obtain the best fit. The two pigment spectra have the same best-fitting curve (solid line; $\lambda_{max} = 530$ nm).

FIG. 3 Sequence of exons 2, 3, 4, and 5 of the MWS pigment gene from a protanope. The locations of the five introns[1] are indicated by arrows. The numbering convention is that of Nathans *et al.*[1]. For the region outside the box (exons 4 and 5), the protanope gene sequence is identical to that of an identified normal MWS pigment gene fragment (gJHN21; ref. 1). For these two exons the underlined nucleotides in the protanope gene sequence are those that differ from corresponding nucleotides in a genomic LWS pigment gene fragment (gJHN33; ref. 1), and the lower amino-acid sequence is that of the identified normal LWS pigment. Exons 2 and 3 (enclosed in the box) of the protanope gene are identical to those of the identified LWS pigment genes in all of the nucleotide substitutions that distinguish the identified normal MWS from the LWS pigment genes[1]. But exons 2 and 3 of the protanope gene differ slightly from those of each of the three genes (one derived from a genomic library and two derived from a human retina cDNA library, no two of which were identical) that Nathans *et al.*[1] identified as encoding normal LWS pigment. For example, exons 2 and 3 of the protanope gene differ from those of the genomic LWS pigment gene fragment (gJHN53; ref. 1) by three nucleotides, but for two of these substitutions the protanope gene is identical to the other two LWS pigment genes, whereas the third is a silent nucleotide substitution (indicated by the asterisk) in which the protanope gene sequence differs from both MWS and LWS sequences. For exons 2 and 3 the nucleotides of the protanope gene that differ from those of a MWS gene fragment (gJHN21; ref. 1) are underlined, and the lower amino-acid sequence is that deduced from the MWS pigment gene (identical amino-acid residues are left blank). A genomic library derived from germ line DNA from the protanope was constructed[14] in the cosmid vector plasmid pWE15 (ref. 15). A fragment containing the protanope MWS pigment gene was identified by its hybridization with a cDNA clone probe. Sequences (both strands) were determined by the dideoxy chain termination method[16].

the red and green mixture of all proportions as matching the yellow light in both small-field (2 degrees) and large-field (11 degrees) versions of the test. The subject was thus a true dichromat[3,4]—a protanope, having only a single X-encoded cone pigment absorbing light of middle to long wavelengths.

We determined the absorption spectrum of this X-encoded cone pigment by analysing a retinal gross potential—the electroretinogram (ERG). To measure relative sensitivity, we adjusted the quantal intensity of a rapidly flickering monochromatic test light to produce a response that matched in amplitude the response to an interleaved flickering reference light[5]. Repetition of this procedure for many test wavelengths yields a curve that accurately characterizes absorption spectra of middle-wavelength-sensitive (MWS) and long-wavelength-sensitive (LWS) cone pigments in dichromatic subjects[5]. The derived sensitivity of the dichromat curve (Fig. 1, ●) thus gave the spectral sensitivity of this MWS pigment. Schnapf *et al.*[6] have measured the spectral sensitivity of normal human cones. The absorption spectra for the protanope MWS cone and the normal MWS cone were very similar (Fig. 1) and the spectral peaks were identical ($\lambda_{max} = 530$ nm).

Southern blots for two different restriction-enzyme digests of genomic DNA from the protanopic subject are shown in Fig. 2. For humans with normal colour vision, similar analysis reveals two hybridizing bands corresponding to two classes of X-linked pigment genes[1]. For the protanopic subject, we observed only a single hybridizing band for each digest, indicating the presence of a single X-linked pigment gene. The earlier identification of the normal pigment genes[1,2] (Fig. 2*a*) enabled us to identify this pigment gene as a fusion gene which had derived its 5′ end from a normal LWS pigment gene and its 3′ end from a normal MWS pigment gene.

We obtained a DNA fragment containing the entire X-linked photopigment gene of the protanope from a library constructed using total genomic DNA, and determined the sequences of exons 2, 3, 4 and 5. Comparison with the normal X-linked pigment genes[1] indicated that this fusion gene had derived its exons 2 and 3 from a normal LWS pigment gene and its exons 4 and 5 from a normal MWS pigment gene (Fig. 3). The fact that the absorption spectrum of the pigment encoded by the fusion gene does not differ from that of a normal MWS pigment indicates that the amino-acid substitutions encoded in exons 2 and 3 have little or no effect on the absorption spectrum of the X-linked photopigments. Nathans *et al.*[1] found no differences between exons 1 or between exons 6 of the MWS and LWS pigment genes. Thus the spectral differences between MWS and LWS pigments seem to be governed entirely by the amino-acid substitutions encoded in exons 4 and 5.

Except for several homologous substitutions[7] (which are not expected to alter the absorption spectrum of the chromophore) all the amino-acid differences between MWS and LWS photopigments that occur in the transmembrane segments encoded by exons 4 and 5 are substitutions of nonpolar groups for hydroxyl-bearing groups[1]. Studies of bacteriorhodopsin demonstrate that similar substitutions of nonpolar for polar groups (for example, Phe for Trp) can have dramatic effects on the absorption spectrum of the chromophore[8]. Depending on their position relative to the chromophore, hydroxyl groups have been proposed to preferentially stabilize or destabilize the ground state relative to the excited state and thus shift the absorption spectrum to the shorter or longer wavelengths[9]. Figure 4 shows the location of all the nucleotide differences responsible for non-homologous amino-acid substitutions that are located in the transmembrane segments encoded by exons 4 and 5. There are two such substitutions in exon 4 and three in exon 5. The most 5′ proximal of these nucleotide substitutions in exon 5 is marked by the restriction site polymorphism that distinguishes fragment D_r from D_g.

The locations and small number of nucleotide substitutions encoding the amino acids that are candidates for producing the spectral difference between X-linked pigments (Fig. 4) limits the number of different pigments with intermediate spectral peaks that can result from genetic recombination. These limitations have implications for understanding the genetic mechanisms underlying the most common forms of defective colour vision—the anomalous trichromacies. Nathans *et al.*[2] propose that the anomalous pigments result from recombination of the identified normal pigment genes. Because all protanomalous individuals that have been studied using Southern blot analysis have fusion genes containing fragment D_g, and all deuteranomalous subjects have fusion genes containing fragment D_r (refs 2, 10), both types of anomalous pigment genes must be produced by crossovers upstream of the D_g-D_r marker. The nucleotide substitutions that give rise to the two hydroxyl-bearing amino-acid substitutions in the MWS exon 4 are separated by only seven nucleotides, so recombination events in the region between them are expected to occur only rarely. These observations suggest that one or both of the substitutions encoded in exon 4 are responsible for the small spectral shift differentiating the X-linked pigments in anomalous trichromats, whereas one or more of the substitutions encoded in exon 5 are

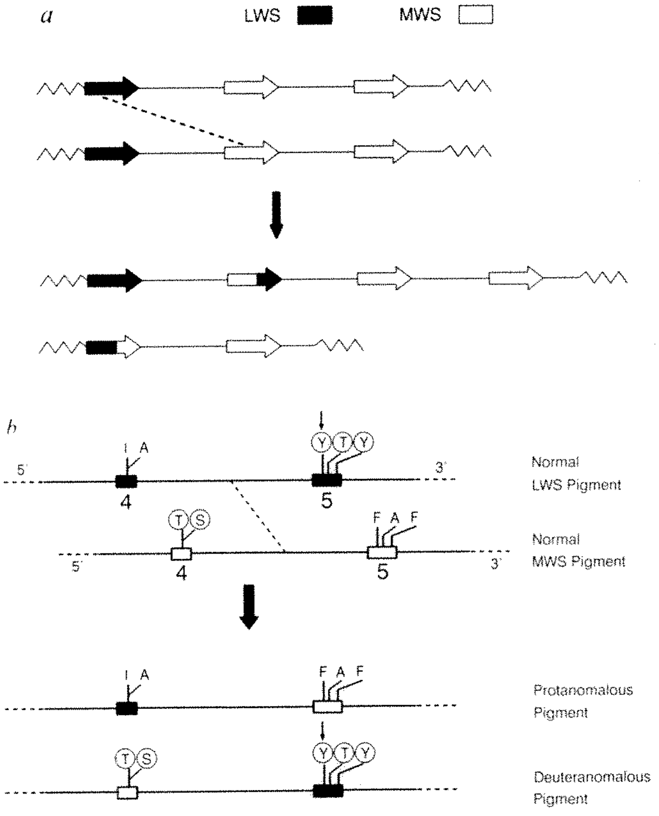

FIG. 4 *a*, Scheme showing how unequal intragenic recombination between normal MWS and LWS pigment genes can produce fusion genes. Each arrow represents a single gene (from ref. 2). *b*, Detail of *a*, showing only exons 4 and 5 of the pigment genes. The locations of nucleotide differences encoding amino-acid substitutions that are candidates for producing the spectral shifts differentiating the products of X-linked pigment genes are labelled according to the amino acid produced. The hydroxyl-bearing amino acids are circled (Y, tyrosine; T, threonine; S, serine), and their nonpolar counterparts are not circled (I, isoleucine; A, alanine; F, phenylalanine). The location of the *Rsa*I site that differentiates restriction fragment D_r from D_g (Fig. 1) is indicated by a small arrow. Cross-overs upstream of the two substitutions in exon 4 produce fusion genes that encode pigments with spectra unchanged from those of products encoded by the original genes. Exchanges in the region between the substitutions in exon 4 and those in exon 5 (such as the one illustrated) are proposed to produce two fusion genes, one that encodes a pigment that is slightly 'red-shifted' from the normal MWS pigment (protanomalous pigment) and a second that is slightly 'green-shifted' from the normal LWS pigment (deuteranomalous pigment).

responsible for the larger spectral shift that differentiates MWS from LWS pigments. It seems that, except for a crossover between the two exon 4 substitutions (Fig. 4), only a single spectrally intermediate protanomalous hybrid pigment and a single spectrally intermediate deuteranomalous pigment could be produced by exchanges upstream of the D_g-D_r marker.

Southern-blot analysis of pigment genes from colour-anomalous subjects does not seem to distinguish between individuals with mild and more extreme forms of anomalous trichromacy. Nathans *et al.*[2] suggest that different locations of crossing over can produce a variety of anomalous pigments with differing spectral peaks, and that this spectral variation accounts for the differences in colour-discrimination ability among anomalous trichromats. The results presented here indicate otherwise—that both mild and extreme forms of protanomalous colour vision are probably based on the same anomalous photopigment and that, similarly, a second anomalous pigment underlies both mild and extreme forms of deuteranomalous colour vision. This conclusion (1) is consistent with recent results from colour matching[3], which show that under conditions designed to maximize colour discrimination, both mild and extreme anomalous subjects make the same colour match and thus seem to have the same anomalous pigment; and (2) reinforces the conclusion reached from psychophysical studies[3,4,11] that tl differences in colour-discrimination ability within each of tl two classes of anomalous trichromats cannot be explained l differences in the absorption spectra of the underlying photopi ments.

COMPELLING evidence indicates that T cells recognize complexes formed by major histocompatibility complex-encoded molecules and antigenic peptide fragments[1-3]. This is based largely on the ability of small synthetic peptides to substitute for naturally processed antigen in stimulating T cells. Naturally processed fragments of exogenous antigen are thought to arise by limited proteolytic degradation of native antigen inside acidic compartments of antigen-presenting cells[3-6], but until now no physiologically processed antigen has been directly analysed. Here we report the characterization of physiologically processed antigen eluted from mouse class II major histocompatibility complex I-E^d molecules. The antigenic material corresponds to a previously described antigenic determinant of hen egg lysozyme (HEL 107-116) and has a relative molecular mass M_r of about 2,000. HPLC analysis identified at least two or three separate molecular species, suggesting limited, albeit significant, heterogeneity of naturally processed peptides. Finally, under our experimental conditions, it was calculated that a substantial proportion (10-40%) of I-E^d molecules were occupied by these HEL-derived antigenic determinants.

Taking advantage of the high stability of the complexes formed between major histocompatibility complex (MHC) molecules and antigenic peptides, we decided to attempt the isolation and characterization of naturally processed HEL peptides from HEL-pulsed A20-1.11 B lymphoma cells (A20 cells). As a first step, we determined whether complexes containing antigenic determinants could be identified in a preparation of affinity-purified class II MHC molecules. For this purpose, I-E^d molecules were purified from a lysate of HEL-pulsed A20 cells (HEL/I-E^d), and inserted into planar membranes[8,9]. These structures strongly stimulated interleukin-2(IL-2) production by the I-E^d-restricted T cell hybridoma 1 H-11.3, for which the sequence HEL 107-116 has previously been identified as th minimal antigenic determinant[7]. Thus, this I-E^d preparatio carried naturally processed material corresponding to the HEI 107-116 determinant (Table 1, first row).

TABLE 1 Isolation of naturally processed antigenic material from antige pulsed B lymphoma cells

Source of I-E^d	Antigen added to purified I-E	IL-2 (U ml)$^{-1}$ produced by 1 H-11.3 T cells
HEL-pulsed A20	Nil	1,280
Unpulsed A20	Synthetic HEL 107-116 (20 ng)	20
Unpulsed A20	Synthetic HEL 107-116 (200 ng)	640
Unpulsed A20	Acid-eluted peptides from HEL/I-E^d	80

A20 cells were grown in RPMI medium supplemented with 5% fetal ca serum, 100 μg ml^{-1} streptomycin, 100 U ml^{-1} penicillin G, and 5 × 10 β-mercaptoethanol. A20 cells were pulsed for 24 h with 1 mg ml^{-1} HE (Grade I, Sigma). I-E^d molecules were purified from both pulsed and unpulse cells by affinity chromatography on 14.4.4 anti-I-E^d monoclonal antibod column[8]. To prepare the acid-eluted peptides, I-E^d (350 μg) was purifie from 1.5 × 10^{10} HEL-pulsed A20 cells (HEL/I-E^d), acetonitrile-precipitate treated for 30 min at 37 °C with 2.5 M acetic acid, and then loaded on Sephadex G-10 column equilibrated with acetate buffer[11]. The peptid material eluted in the void volume was collected and lyophilized twic Complexes between I-E^d and peptides prepared *in vitro* were obtained b dissolving the lyophilized peptides in 10 μl phosphate-buffere saline/100 mM Tris-HCl, pH 7.2, supplemented with 1 mg ml^{-1} sodium azid and a cocktail of protease inhibitors (16 mM EDTA, 2.6 mM 1,10-phenanthrc line, 0.15 mM pepstatin A and 2 mM PMSF) (ref. 10), and 10 μl of a 1 2 mg ml^{-1} I-E^d preparation. After incubating for 1 d at room temperatur the samples were diluted to 250 μl with PBS containing 1 mg ml^{-1} sodiur azide, 1% *n*-octyl-β-D-glucopyranoside (Sigma), 175 μg ml^{-1} L-α-phos phatidylcholine (Sigma), and 25 μg ml^{-1} cholesterol (Sigma). I-E^d-peptid complexes were inserted into planar membranes and tested in a T-ce stimulation assay as described[8,9].

The next step in this series of experiments would be to dissoci ate the antigenic determinants from the I-E^d molecules an biochemically characterize them. For this purpose, it wa necessary to devise as sensitive an assay as possible. To decreas the amount of antigenic material required to trigger IL-2 releas by the 1 H-11.3 T cell hybridoma, we formed I-E^d/peptid complexes *in vitro*, under conditions already established a optimal[10], and used these complexes, inserted into planar mem-

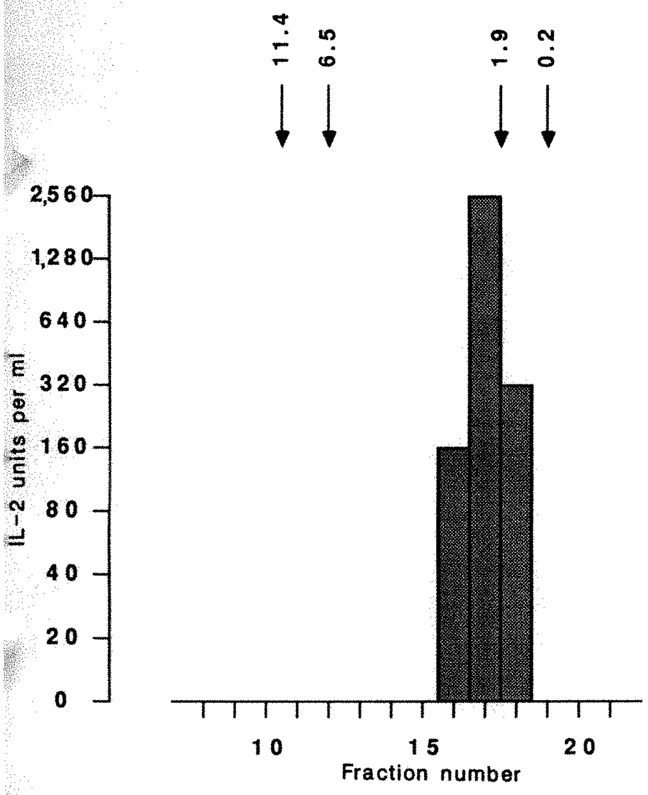

FIG. 1 Gel filtration analysis of a naturally processed I-E^d-restricted determinant of lysozyme.

METHODS. Acid-eluted material obtained from 600 μg HEL/I-E^d complexes (Table 1) was loaded on a Sephadex G-50 column (1.5 × 90 cm) equilibrated with 60 mM ammonium acetate buffer, pH 4.8 (ref. 11). Fractions (8 ml) were collected and lyophilized twice. One-fifth of each fraction was tested as described in the legend to Table 1. The positions of molecular weight markers are indicated (M_r 11.4 K, cytochrome *c*; 6.5 K, aprotinin; 1.9 K, Y-HEL 105–120; 0.2 K, $Cr_2O_7^{2-}$). In this experiment, I-E^d complexes prepared with 20 ng and 200 ng synthetic HEL 107–116 peptide stimulated 1 H-11.3 T cells to produce 1,280 U ml^{-1} IL-2 and >2,560 U ml^{-1} IL-2, respectively.

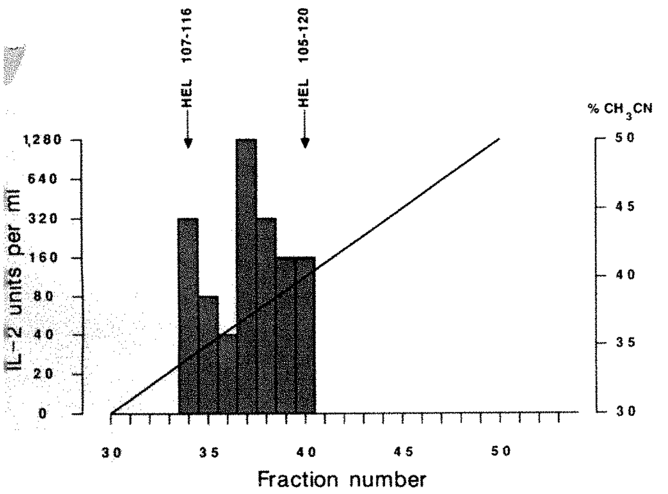

FIG. 2 Reverse-phase HPLC analysis of a naturally processed I-E^d-restricted determinant of lysozyme.

METHODS. Acid-eluted material obtained from 350 μg HEL/I-E^d complexes (Table 1) was separated on a μ-Bondapak C-18 reverse-phase HPLC column (Waters System) by forming a linear gradient of 0.08% trifluoroacetic acid in water and 0.08% trifluoroacetic acid in acetonitrile (1% per min). Fractions (1 ml) were collected, lyophilized, and tested as described in the legend to Table 1. The elution positions of the synthetic HEL 107–116 and HEL 105–120 peptides are indicated.

branes, in the T cell hybridoma stimulation assay[8,9]. Following this approach, we could detect as little as 20 ng HEL 107–116 peptide (Table 1), whereas, if directly added to antigen-presenting cells, 250 ng were required to reach similar levels of T-cell stimulation (ref. 7, and data not shown).

A crude preparation of peptides bound to HEL/I-E^d complexes was obtained by acid treatment of acetonitrile-precipitated HEL/I-E^d material, followed by Sephadex G-10 chromatography[11]. As assessed by SDS-gel electrophoresis, this step completely depleted the acid-eluted HEL/I-E^d peptide preparation of I-E^d molecules (data not shown). The acid-eluted HEL/I-E^d peptides were then incubated with I-E^d molecules purified from A20 cells grown in the absence of any HEL material, and the putative complexes were inserted into planar membranes as already described. These antigen-presenting structures stimulated IL-2 release from 1 H-11.3 T cells, indicating that peptide material containing the HEL 107–116 sequence had been eluted from the I-E^d isolated from cells incubated with HEL, and that these peptides could be rebound to I-E^d molecules (Table 1, last row). Similar data were obtained in the case of an I-A^d-restricted and ovalbumin 323–339 peptide-specific T cell hybridoma (data not shown).

To initiate the characterization of this acid-eluted HEL/I-E^d material, the molecular weight was estimated by gel filtration on a Sephadex G-50 column. Each fraction was tested for its capacity to produce, when recombined to I-E^d, complexes antigenically active for 1 H-11.3 T cells. Stimulatory material was eluted in a single homogeneous peak, with an apparent relative molecular mass of ~2,000 (M_r 2K) (Fig. 1).

To further characterize the naturally processed HEL-derived material, an acid-eluted peptide preparation was subjected to reverse-phase HPLC and each fraction was tested for its capacity, when incubated with I-E^d, to form T-cell stimulatory complexes. Material antigenic for 1 H-11.3 T cells was eluted between 34–40% acetonitrile. The activity profile suggested that at least two or three peptide species were produced by A20 cells during processing of HEL molecules (Fig. 2). The synthetic peptides HEL 107–116 and HEL 105–120 eluted at 34% and 40% acetonitrile, respectively, suggesting that the HEL fragments generated by A20 cells are not grossly dissimilar from these peptides.

To evaluate the possibility that limited degradation of the antigenic material occurred during the isolation procedure, a radioiodinated synthetic peptide corresponding to [^{125}I]Y-HEL 105–120 was purified as described. No degradation could be detected by reverse-phase HPLC, indicating that the antigenic HEL peptides that we characterized were representative of those peptides produced by processing in A20 cells (data not shown).

This assay allowed us to estimate directly the proportion of I-E^d molecules on HEL-pulsed A20 cells that were occupied by peptides containing the HEL 107–116 determinant detected by 1 H-11.3. We therefore compared the antigenicity of an I-E^d preparation from HEL-pulsed A20 (HEL/I-E^d) with synthetic HEL 107–116/I-E^d complexes prepared *in vitro*. The amount of synthetic HEL 107–116 peptide bound to I-E^d molecules was first determined by Scatchard analysis, as previously described[10]. Thus it was calculated that under saturating concentrations of HEL 107–116 peptide (>10 μg ml^{-1}), 7.5% of I-E^d molecules were occupied by this peptide. Then various amounts of synthetic HEL 107–116/I-E^d complexes were inserted into planar membranes, and the capacity to stimulate 1 H-11.3 T cells was measured for each (Fig. 3). The total amount of I-E^d molecules inserted into each planar membrane sample was kept constant by adding I-E^d molecules purified from unpulsed A20 cells, to obtain a direct correlation between the T-cell response and the density of antigenic complexes borne by the planar membranes. The response to the synthetic HEL 107–116 peptide/I-E^d complexes was then compared with naturally processed HEL. It was found that HEL/I-E^d complexes inserted at 16 nM into planar membranes stimulated 1 H-11.3 T cells to produce 640 U ml^{-1}

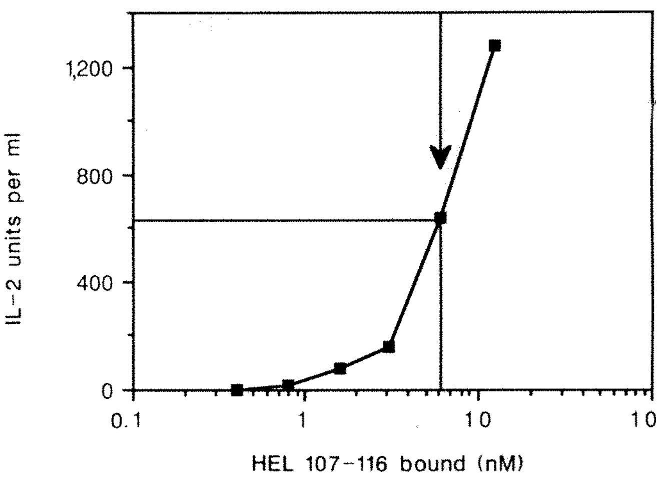

FIG. 3 Occupancy of I-E^d molecules purified from HEL-pulsed B lymphoma cells by HEL 107–116-containing determinants. To generate a standard curve, various concentrations of synthetic HEL 107–116 peptide bound to I-E^d molecules and inserted into planar membranes were tested for their ability to trigger 1 H-11.3 T cell stimulation. Then a known concentration of I-E^d purified from HEL-pulsed A20 cells (16 nM) was inserted into planar membranes and used to stimulate 1 H-11.3 T cells. An equivalent stimulation to 6 nM of synthetic peptide HEL 107–116/I-E^d complexes was obtained. METHODS. The concentration (nM) of purified I-E^d molecules able to bind antigen was determined by Scatchard analysis[10]. The amount of synthetic HEL 107–116 peptide necessary to fully saturate the same I-E^d molecules was measured by testing a dose range of synthetic HEL 107–116 peptide for its capacity to abrogate binding of ^{125}I-radiolabelled λ-repressor 12–26 peptide[10]. I-E^d molecules (0.5 mg ml^{-1}) were then incubated with 1 mg ml^{-1} synthetic HEL 107–116 peptide (30-fold excess over the saturating dose), using the same conditions as in the binding assay (see Table 1 legend). After the incubation, I-E^d molecules were recovered from free peptide by passage over a Sephadex G-50 column and inserted into planar membranes[8,9]. The total amount of I-E^d molecules inserted was kept constant (10–25 μg ml^{-1}) by adding I-E^d molecules purified from unpulsed A20 cells. In parallel, I-E^d molecules were prepared from HEL-pulsed A20 cells, inserted into planar membranes, and tested for 1 H-11.3 T cell stimulation. As before, I-E^d concentration was adjusted at ~25 μg ml^{-1} by the addition of I-E^d purified from unpulsed A20 cells.

IL-2. A similar T-cell activation was reached with 6 nmol synthetic HEL 107–116 peptide bound to I-E^d molecules (Fig. 3). Assuming that HEL 107-116/I-E^d complexes were as stimulatory as naturally processed HEL/I-E^d complexes, these data would indicate that 38% of the I-E^d molecules expressed by HEL-pulsed A20 cells were occupied by HEL 107-116-like determinants.

An independent estimate of the extent of occupancy was based on the amount of antigenic peptides eluted from an HEL/I-E^d preparation after its separation by G-50 gel filtration separation. In this experiment, antigenic material obtained from 2 nmoles of I-E^d yielded T-cell stimulatory activity corresponding to 2,000–3,000 U ml^{-1} IL-2 (Fig. 1). Similar levels of IL-2 production were attained using ~0.2 nmol synthetic HEL 107-116 peptide. So by this calculation it seems that ~10% of the I-E^d molecules purified from HEL-pulsed A20 cells carried HEL 107-116 determinants. This value is probably a minimal estimate as the G-50 fractions would also be expected to contain non-HEL-derived I-E^d-binding peptides which would tend to compete with and lower the efficiency of binding of the HEL peptides to I-E^d (ref. 11).

In conclusion, the preparation of complexes between MHC molecules and antigenic peptides allowed us to characterize a naturally processed determinant of HEL. The heterogeneity of the antigenic peptides produced by A20 cells may be due to cleavages at different positions in the HEL sequence, reflecting the use of either different proteases or proteases displaying a broad substrate specificity.

Quantitation of the proportion of I-E^d from HEL-pulsed A20 cells bearing HEL 107-116-containing determinants gave surprisingly high estimates (10–40%). These data can be rationalized, at least in part, by considering that HEL represented, under our experimental conditions, about one-third of the total extracellular protein (1 mg ml^{-1} HEL and 2–3 mg ml^{-1} of fetal calf serum proteins). Furthermore, the HEL 107-116 peptide region is the chief I-E^d binding site of HEL (ref. 7). We cannot exclude the possibility, however, that there are covalent modifications of antigenic material which increase its antigenic potency[12]. Direct sequencing of naturally processed antigenic peptides should solve these issues. □

EXCITATORY amino acids (EAAs) are important neurotransmit ters in the vertebrate central nervous system[1]. Electrophysiologica and ligand-binding studies indicate that at least three differen receptor subtypes for EAAs exist—*N*-methyl-D-aspartate, kainat and quisqualate receptor subtypes—on the basis of the preferre agonist of the receptors[1,2]. We recently purified a kainate-bindin protein (KBP) from frog (*Rana pipiens berlandieri*) brain b domoic acid (a high-affinity kainate analogue) affinit

FIG. 1 *a*, Restriction enzyme map of cDNA clones encoding the KBP. Thick lines represent regions that are used to construct an expressible cDNA containing an entire open-reading frame. Broken line shows the regions not sequenced. Positions of the initiator methionine codon and stop codon of an open reading frame are shown by ATG and TAG, respectively. *b*, Nucleotide and deduced amino-acid sequence (single-letter code) of the KBP cDNA. Only the sequences used for the expression studies are shown. Nucleotides and amino acids are numbered in order, starting with the first residues. Amino-acid residues with asterisks show the chemically obtained KA2 sequence. Individually underlined amino-acid residues show the predicted signal peptide sequence[10]. Underlined sequences indicate the putative transmembrane domains predicted by regional hydropathy analysis[16,17]. Potential *N*-linked glycosylation sites[11] are indicated by #.

METHODS. KBP was isolated from frog brain by domoic-acid affinity chromatography[3]. The protein was further purified by SDS-PAGE. The main band migrating to a position corresponding to an M_r of 48,000 was excised, digested with *S. aureus* V8 protease in a stacking gel, and fractionated by electrophoresis on a 15% SDS-polyacrylamide gel. The gel was electroblotted onto an Immobilon membrane (Millipore, Bedford, Massachusetts). After staining with Coomassie blue, pieces containing the main digested fragments were excised and microsequenced. One long amino-acid sequence (KA2) was obtained from one of the fragments (single-letter code): SSYMFGFLNPFSKELXIGIIISYVIT, where X is an unidentified residue. Sense and antisense 20-base oligonucleotides were made using all possible codon combinations encoding the sequence near the N and C termini of KA2, respectively: 5′-TAYATGTTYGGNTTYYTNAA-3′, 5′-ACRTANSWDATDATDATNCC-3′. R, A or G; S, C or G; W, A or T; Y, C or T; D, A or G or T; and N, A or C or G or T. PCR (ref. 8) was performed using the oligonucleotides as primers and frog liver genomic DNA as a template. Frog liver genomic DNA was prepared by a standard method[24]. Annealing reactions were performed at 50 °C for 2.5 min, followed by a 3.5-min extension at 72 °C and 1-min denaturation at 94 °C. After 35 rounds of amplification, PCR-extended fragments of 65-bp were purified, subcloned into the *Sma*I site of the plasmid pGEM 3Z (Promega, Madison, Wisconsin) and sequenced[25]. Based on this resultant sequence, 65-base oligonucleotides were prepared and used to screen a frog brain cDNA library (Clontech, Palo Alto, California) in λgt11 vector: 5′-TACATGTTCGGGTTTCTGAACCCTTTCTCCAAGGAGCTGTGTATCGGCATCATCATAACCTACGT-3′. Hybridization and washing of filters were carried out according to a standard method[24]. The isolated cDNAs were subcloned into the plasmid pBluescript KS (+) (Stratagene, La Jolla, California) and sequenced[25]. Some nucleotide sequence differences were found between the PCR product and the KBP cDNA. These could have been due to replication errors of the reverse transcriptases and DNA polymerases used, and/or to genetic polymorphism among frogs.

chromatography[3], and showed that the kainate-binding activity was associated with a protein of relative molecular mass 48,000 (M_r 48 K)[3,4]. The pharmacological properties and the anatomical distribution of KBP were consistent with those of a kainate receptor–ionophore complex[3–5]. We have now isolated a complementary DNA encoding KBP of M_r 48 K. The deduced amino-acid sequence of the KBP has similar hydrophobic profiles to those found in other ligand-gated ion channel subunits[6], and shows some amino-acid sequence similarities to the corresponding regions of brain nicotinic acetylcholine receptor subunits[7]. Localization of the KBP messenger RNAs by *in situ* hydridization histochemistry is compatible with the results of immunohistochemistry and receptor autoradiography studies[5]. COS-7 cells transfected with the cDNA encoding the KBP show high-affinity kainate-binding activity with pharmacological properties similar to those of the biochemically purified KBP (ref. 3). These results provide the first molecular characterization of an EAA-binding site and raise the possibility that the KBP cDNA encodes a ligand-binding subunit of a kainate receptor–ionophore complex.

A sequence of 26 amino-acid residues (referred to as KA2), as well as other shorter sequences, was obtained from the peptide fragments of the purified KBP which had been digested with *Staphylococcus aureus* V8 protease. Because none of the peptide sequences contained a suitable region to make oligonucleotide probes with little degenerativity, we used the polymerase chain reaction (PCR) procedure[8] to obtain a precise nucleotide sequence for KA2 (see Fig. 1 legend for experimental details). A fragment of genomic DNA of the expected length was amplified from a pool of frog liver genomic DNA. Sequenc analysis of the fragment revealed a nucleotide sequence tha encoded the KA2 sequence between the two regions used t prepare the primers. The revealed nucleotide sequences and th primer sequences in the PCR product were used to make a lon oligonucleotide probe to screen a frog brain cDNA library i λgt11 vector. From 7×10^5 recombinants, four clones were isolated and used to obtain longer cDNA clones. Four overlappin longer clones (FKA16A, FKA27C, FKA17A and FKA15C) wer obtained from a total of 1.4×10^6 recombinations and studie further (Fig. 1*a*).

Sequence analysis of these clones showed a 1,461-base-pai (bp) open-reading frame potentially encoding 487 amino-aci residues (Fig. 1*b*). The sequence around the predicted initiato methionine codon (ATG) agrees with the consensus sequenc described by Kozak[9]. The deduced amino-acid sequence show a hydrophobic segment at the N terminus, which probabl encodes a signal peptide. The N terminus of the mature protein was predicted by the method of von Heijne[10]. The proposed mature protein is preceded by a signal peptide of 17 residues and composed of 470 amino-acid residues with a calculated M of 52.5 K. Two potential *N*-linked glycosylation sites[11] are found at position 78 and 96 in the putative N-terminal extracellular segment. The amino-acid sequence of the predicted mature protein contains the KA2 sequence at residues 150–175. Other shorter amino-acid sequences obtained by the microsequencing of the V8 protease-treated fragments are also found at residues 57–66, 62–74, 110–125 and 353–366.

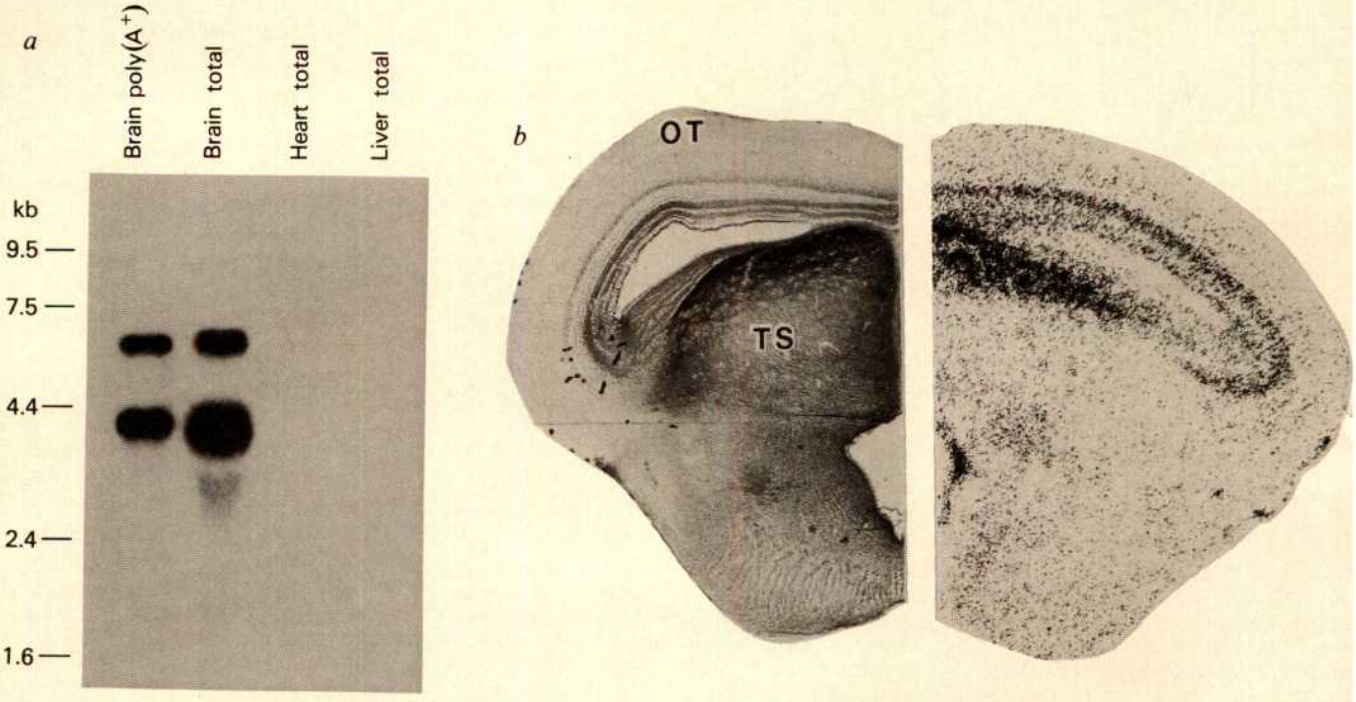

FIG. 2 *a*, Northern-blot analysis of the KBP mRNA. *b*, Comparison of labelling pattern in frog brain with immunostaining of KBP (left) and *in situ* hybridization histochemistry of KBP mRNA (right). Coronal sections of mesencephalon and optic tectum are presented. TS, Torus semicircularis; OT, Optic tectum.

METHODS. *a*, Frog brain total and poly(A)$^+$ RNA, and frog heart and liver total RNAs were prepared using a standard method[26]. Each total RNA (10 μg) and 0.5 μg poly(A)$^+$ RNA were electrophoresed on a 1% formaldehyde-agarose gel and blotted onto a nitrocellulose membrane. Hybridization was carried out in a buffer containing 5×SSC and 50% formamide at 42 °C. The pBluescript plasmid containing the expressible KBP cDNA sequence was used as a probe. The membrane was washed with 2×SSC at 55 °C and exposed overnight. The same pattern of signals was obtained after a very high stringency wash with 0.1×SSC at 70 °C. *b*, Immunohistochemistry was performed as previously described[5]. After incubating with the monoclonal antibody, KAR-A1 (refs 4, 5), immunostaining was visualized with avidin–biotin–peroxidase complex. *In situ* hybridization histochemistry was performed on freshly frozen frog brain sections. Sections (15 μm) were cut on a cryostat and mounted onto gelatin- and poly-L-lysine-coated slides. After fixation in phosphate buffer containing 4% paraformaldehyde for 10 min at 4 °C followed by rinsing in 2×SSC, sections were hybridized with ^{35}S-labelled oligonucleotide probes overnight in buffer containing 5×SSC and 50% formamide at 37 °C. Two 48-base oligonucleotides complementary to the sequences at residues 421–468 and 469–516 (Fig. 1) were used as probes. After hybridization, slides were washed in 0.5×SSC at 40 °C, dehydrated and exposed to X-ray films for 20 days. For higher resolution studies, slides were then dipped in Kodak NTB-3 nuclear emulsion and exposed for 3 weeks. An oligonucleotide probe encoding the sense strand (residues 421–468) was used as a negative control. Both antisense oligonucleotide probes gave the same results.

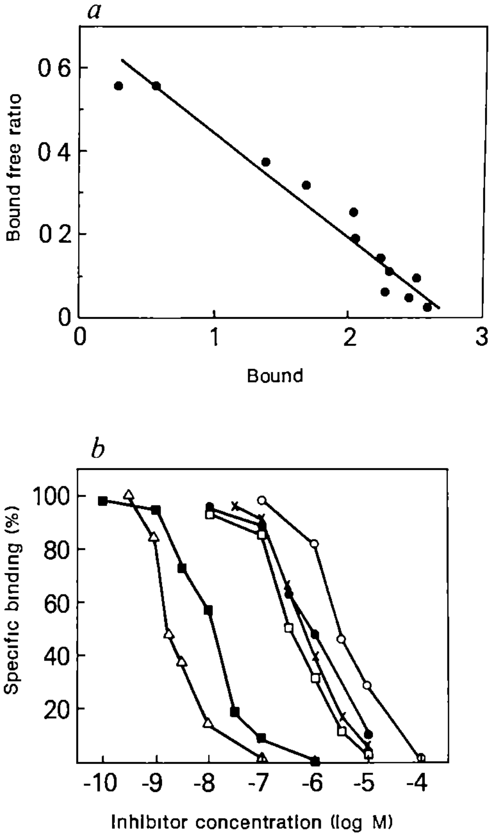

FIG 3 *a*, Scatchard analysis of ^{3}H-labelled kainate binding to transfected COS-7 cell membranes Binding was performed at concentrations of 0 5–100 nM Data were analysed using the LIGAND program[13], and found to fit a single-site model A K_d of 5 6 ± 0 7 nM (mean ± s d , $n = 3$) was obtained Values for the maximum number of binding sites were 2 8 and 3 1 pmol per mg protein for two separate batches of cells Bound are expressed as pmol ^{3}H-labelled kainate per mg protein and bound free ratio is expressed as pmol ^{3}H-labelled kainate per mg protein per nM *b*, Inhibition profiles of various ligands for ^{3}H-labelled kainate binding to the transfected cells Values of 50% inhibitory concentration IC$_{50}$ (mean ± s d , $n = 3$) were 2 7 ± 0 7 nM for domoic acid (△), 13 2 ± 0 5 nM for kainate (■), 0 59 ± 0 35 μM for quisqualate (□), 0 80 ± 0 35 μM for glutamate (●), 0 83 ± 0 13 μM for 6-cyano-7-nitroquinoxaline-2,3-dione (×), and 4 1 ± 1 2 μM dihydrokainate (○)

METHODS An expressible cDNA containing an entire open-reading frame was constructed as follows (see also Fig 1) The cDNA insert of FKA 27C was subcloned into *Eco*RI site of the plasmid bBluescript KS(+) (Stratagene) The *Hin*dIII-*Kpn*I fragment of FKA 17A, the *Kpn*I-blunt-ended *Acc*I fragment of FKA 15C and the *Hin*dIII-*Hin*cII fragment of the plasmid containing FKA 27C cDNA were ligated to yield FKA 271715 The *Bgl*II-*Acc*I fragment of FKA 16A and the *Bam*HI-*Acc*I fragment of the FKA 271715 were ligated to yield FKA 16271715 The *Xba*I-*Apa*I fragment of the plasmid FKA 16271715, containing the expressible cDNA, was subcloned under the SV40 early promoter of a modified form of the plasmid, pcD2 (ref 12) The modified pcD2 plasmid was made by the introduction of multiple cloning sites at *Pst*I and *Bam*HI sites of the original plasmid pcD2 vector The sequence encoding the introduced multiple cloning sites was 5′-TGCAGTCTAGACCCGGGAATTCGGGCCCGGATC-3′ COS-7 cells (5 × 10^5 per 10-cm plate) were cultured overnight and transfected with 20 μg plasmid pcD2 DNA containing the expressible FKA cDNA insert by a calcium phosphate method[12] After 24 h, the medium was changed and plates were incubated for an additional 4 days Cells were collected in distilled water, centrifuged at 54,000*g* for 20 min, resuspended with a polytron in distilled water, and centrifuged at 54,000*g* for 20 min Membrane fractions were frozen as pellets and stored at −70 °C For binding studies, frozen membranes were resuspended with a polytron in 50 mM Tris-HCl, pH 7 0, and centrifuged at 54,000*g* for 20 min The membranes were washed two additional times and subjected to ^{3}H-labelled kainate binding as previously described[3] Untransfected COS-7 cells had no binding activity for ^{3}H-labelled kainate For displacement studies, inhibitors were incubated with membranes for 10 min before addition of ^{3}H-labelled kainate at a final concentration of 5 nM

Northern blot analysis with KBP cDNA probe showed that two principal transcripts of 6 and 4 kilobases were found in frog brain (Fig 2*a*) *In situ* hybridization histochemistry on frog brain sections demonstrated that the pattern of expression of the KBP transcripts was similar to those of the biochemically purified KBP and ^{3}H-labelled kainate-binding sites (Fig 2*b*, and ref 5) The KBP transcripts were abundantly expressed in the torus semicircularis and the optic tectum Higher resolution study revealed that the transcripts were distributed in layers 2, 4 and 6 of the optic tectum Dendrites from neurons in these layers project into layers 3 and 5, where immunostaining was apparent[5]

An expressible cDNA containing the entire open-reading frame was constructed using appropriate restriction-enzyme-digested fragments from the four positive clones in Fig 1*a*, and subcloned under the SV40 early promoter in a modified form of the plasmid pcD2 vector[12] The plasmids were transfected into COS-7 cells by a calcium phosphate method[12] Membrane fractions of the transfected cells were prepared 4 days after transfection and assayed for ^{3}H-labelled kainate-binding activity Scatchard analysis[13] indicated that the membrane fraction of the transfectants contained a single class of ^{3}H-labelled kainate-binding sites with a dissociation constant (K_d) of 5 6 nM (Fig 3*a*) Purified frog brain KBP has both a high ($K_d = 5\ 5$ nM)- and a low ($K_d = 34$ nM)-affinity binding site for ^{3}H-labelled kainate[3] Lack of the low-affinity binding site in the transfectants could indicate the existence of another subunit in the purified frog brain protein Alternatively, different post-translational modifications between frog brain and transfected COS-7 cells could explain the absence Displacement of ^{3}H-labelled kainate binding with selective ligands showed similar patterns to those found in the biochemically purified KBP (Fig 3*b*, and ref 3) Immunoblotting analysis of the membrane preparation using polyclonal antisera against the purified frog KBP revealed that the isolated KBP cDNA produced a protein with a migration rate on SDS-PAGE similar to that of the purified KBP of M_r 48 K (data not shown)

Although the expressed protein in transfected cells could bind kainate, injection of mRNA, transcribed *in vitro* using the bacterial RNA polymerase from the cDNA encoding the entire KBP, did not produce a detectable electrophysiological response to perfused kainate in *Xenopus laevis* oocytes by a two-microelectrode voltage-clamp method In preliminary experiments, co-injection of oligonucleotides complementary to the KBP cDNA sequence with frog brain poly(A)$^+$ RNA[14 15] did not significantly repress an electrophysiological response to kainate compared with control

Analysis for regional hydrophobicity[16,17] of the deduced amino-acid sequence for the KBP revealed four putative transmembrane domains The distribution and spacing of the domains are similar to those seen in various subunits of ligand-gated ion channels, including nicotinic acetylcholine receptors (nAChRs)[7], glycine receptor[14] and γ-aminobutyric-acid receptors[18] (Fig 4*a*) This hydrophobic profile is one of the common structural features presumed to be important for the function of the ligand-gated ion channels[6] But neither the two cysteine residues in the predicted N-terminal extracellular segment nor the proline residue in the first proposed transmembrane domain, which are other important structural features conserved in ligand-gated ion channel subunits[6], is found in the KBP The KBP has a shorter N-terminal and a longer C-terminal hydrophilic segment than do the ligand-gated ion channel subunits

Although homology search in a sequence bank (NBRF) revealed no strong similarities to known proteins, some amino-acid sequence similarity to neuronal nAChR subunits[7] could be found in particular segments, especially in the proposed fourth transmembrane domain (Fig 4*b*) The sequence alignment of the KBP and neuronal nAChR α_2-subunit shows that the serine residue in the proposed second transmembrane domain is conserved (Fig 4b) The equivalent residue in *Torpedo* and muscle nAChR subunits is important for ion transport[19,20] The KBP has negatively charged amino-acid residues around the second putative transmembrane domain Negatively charged amino-acid residues seen in the homologous region of the *Torpedo* nAChR subunits have been proposed to form anionic rings, which are important determinants of the cation transport rates[21] Like the nAChRs, kainate receptors are known to be cation-transfer ion channels[1]

The results presented here show that the KBP cDNA encodes a kainate-binding protein that cannot form a functional channel when expressed alone There are two general interpretations for this finding The first is that the KBP cDNA does not encode a neurotransmitter receptor subunit, but rather an uncharacterized kainate-binding molecule, which may or may not be related to EAA neurotransmission The preliminary results of the complementary oligonucleotide blocking experiments and the lack of certain common structural features in the KBP, which are presumed to be important for channel function and found all ligand-gated ion channel subunits sequenced so far, coul support this interpretation Because KBP is the principal kai ate-binding protein in frog brain[3-5], this interpretation woul imply that most or all of the kainate-binding sites are n associated with a kainate receptor-ionophore complex The fa that the KBP has some structural properties of known ligan gated ion channel subunits indicates that such a binding prote is evolutionarily and functionally related to a recepto ionophore complex

The second interpretation is that the KBP cDNA encodes subunit of a kainate-gated ionophore that requires an addition subunit(s) for physiological activity The requirement of mult ple subunits to produce a functional receptor-ionophore con plex is well documented for nAChRs (refs 7, 22, 23) Injectio of *Torpedo* nAChR α-subunit mRNA alone produces a prote with ligand-binding activity but no channel activity in *Xenop* oocytes[22] Furthermore, the following observations in the prese study support the idea that the KBP is related to a function receptor-ionophore complex (1) COS-7 cells transfected wi the KBP cDNA could bind kainate, (2) hydrophobic profil of the KBP were similar to those of other ligand-gated io channel subunits, (3) some sequence similarities to nACh

FIG 4 *a*, Comparison of hydropathy profiles of the KBP α_2-subunit of rat nAChR[7], strychnine-binding subunit of rat glycine receptor (GlyR)[14] and β_1 subunit of bovine γ-aminobutyric acid receptor (GABAR)[18] Scores of hydropathy were computed according to Kyte and Doolittle[16] (solid line) and Engelman, Steitz and Goldman[17] (broken line) with window sizes 9 and 20, respectively Solid bars indicate proposed transmembrane domains

b, Alignment of the amino-acid sequence of the KBP and nAChR α_2 subunit[7] in the putative transmembrane domains Identical residues are indicated by vertical lines Colons indicate conservative substitution of amino-acid residues[27] Gaps of sequence are inserted to achieve maximum similarities Dashes show the sequences not compared TMD, Transmembrane domains subunits were found in certain segments, and (4) there could be an additional homologous subunit(s) forming a functional receptor together with the KBP This possibility is supported by the fact that two bands were detected by northern blotting at high stringency, and that multiple proteins at positions corresponding to a M_r of 48,000 on an SDS-polyacrylamide gel were recognized by immunostaining using polyclonal and monoclonal antibodies against the KBP (refs 3, 4) Furthermore, the KBP cDNA encodes a protein that produces only a high-affinity binding site for kainate in COS-7 cells Although the lack of the previously observed lower-affinity site[3] could be due to different post-translational modifications between frog brain and transfected COS-7 cells, it raises the possibility that a second protein, which contains the low-affinity binding site, is necessary for a physiologically functional receptor

This study provides the first molecular characterization of a component of a kainate receptor-binding system that could be involved in EAA neurotransmission Recent evidence has shown that EAAs are important neurotransmitters in the central nervous system and could be involved in neurotoxicity and several other neurological disorders[1 2] This provides an impetus to characterize their receptors and related proteins Further studies focused on isolating and expressing additional subunits of KBP should help elucidate the precise role of the protein and its relationship to neurotransmission and kainate neurotoxicity ☐

KAINATE receptors mediate some of the excitatory transactions carried out in the central nervous system by the neurotransmitter glutamate[1] They are involved in neurotoxicity[2], possibly in neurodegenerative disorders[3] and it has been suggested that they have a role in long-term potentiation[4] Kainate receptors are present both on neuronal[1] and glial[5–7] cell membranes where they regulate the gating of a voltage-independent ion channel[8] Nothing is known about their molecular structure Taking advantage of the unusually high abundance of ^{3}H-kainate binding sites in the chick cerebellum[9,10], we have isolated an oligomeric protein that displays a pharmacological profile similar to that of a kainate receptor, and have demonstrated, using the monoclonal antibody IX-50, that this protein is composed of a single polypeptide of M_r 49,000 which harbours the specific kainate recognition site[11] The structure of this kainate binding protein (KBP) is also of interest because of its exclusive cerebellar localization on Bergmann glial membrane[12] in close proximity to established glutamatergic synapses[13] We now report the isolation of the complementary DNA containing the complete coding region of the kainate binding protein The predicted structure of the mature protein has four putative transmembrane domains with a topology analogous to that found in the superfamily of ligand-gated ion channels[14–16] This raises the possibility, that kainate binding protein may form part of an ion channel and may be a subunit of a kainate subtype of glutamate receptor

The chick cerebellar kainate binding protein (KBP) was isolated as previously described[11], as a single polypeptide of M_r 49K with a purity, estimated on SDS-polyacrylamide gels, of 80–95% KBPs with similar M_r values have been isolated from frog[17] and pigeon[18] brain Microsequencing of the N terminus of purified KBP produced only one sequence To obtain internal amino-acid sequences of KBP, the latter was fragmented with cyanogen bromide and the five most prominent peptides (I–V), obtained on separation by reverse-phase HPLC, were submitted to N-terminal sequence analysis (P G and V I T, manuscript in preparation) All sequences determined chemically are shown (solid lines) in Fig 1

As peptide IV was immunopositive with monoclonal antibody IX-50 and polyclonal antibodies (data not shown) we synthesized a set of 20-nucleotide-long oligodeoxyribonucleotides (oligo(dT)) corresponding to its N terminus (probe IV, see Fig 2 legend) To establish its suitability for screening libraries and the optimal hybridization conditions, probe IV was used to analyse RNA blots As shown in Fig 2*a* (panel A), probe IV hybridized mainly to a 3 9-kilobase (kb) RNA, but also to a 6-kb RNA Both of these are much more abundant in the cerebellum than in the cerebrum and not detectable in the liver This tissue distribution correlates very well with that of kainate-binding sites[19] and with anti-KBP immunoreactivity (data not shown) Analysis of RNA blots with probe I, derived from the sequence of peptide I, gives an identical pattern to the one shown in Fig 2*a*, panel A

An oligo(dT)-primed chick cerebellar cDNA library, constructed in phage λgt-10, was screened with the probe IV (for methods, see Fig 2 legend) Positive phages were rescreened with probe I and cDNAs KBP-2 9 and KBP-2 2 were isolated Radiolabelled KBP-2 2 cross-hybridizes to KBP-2 9 and gives the anticipated hybridization pattern on northern blots (Fig 2*a*, panel B) Rescreening the same library with restriction fragments of cDNA KBP-2 2 resulted in isolation of the clone KBP-3 3, which has the complete coding region of KBP The maps of clones used to establish the coding DNA sequence of KBP are shown in Fig 2*b*

The entire protein-coding DNA sequence and deduced amino-acid sequence of KBP are shown in Fig 1 The mature protein is predicted to have 464 amino acids and an M_r of 51 8K The 23 residues preceding the N-terminal sequence probably constitute the signal peptide The first methionine is preceded by an in-frame stop codon and has a sequence context consistent with its use as a translation start site[20] Although we have not formally shown that the cloned cDNA expresses a protein with kainate-binding properties, several arguments indicate that the derived amino-acid sequence corresponds to that of KBP First, the deduced amino-acid sequence contains all the peptide sequences derived from the pure 49K polypeptide harbouring the kainate-binding site[11] Second, two of the encoded peptides (IV and V) provide determinants for polyclonal antibodies directed against KBP and peptide IV is recognized by the anti-KBP monoclonal antibody IX-50 Third, the amino-acid composition and size of the deduced sequence are, within limits of error, consistent with those of isolated KBP Finally, the preferential cerebellar localization of the RNA species hybridizing to the cloned cDNA is strictly in line with the selective tissue distribution of KBP

Data-base searches did not reveal any significant sequence homology of KBP to other proteins A comparison of the overall pattern of hydrophobic residues for KBP with such patterns for known ligand-gated channels (Fig 3), however, revealed some similarities The KBP contains several hydrophobic regions including prominent ones near the N and C termini of the protein In addition, there are three stretches of hydrophobicity between residues 140 and 240, each of which is long enough to span a lipid bilayer in an α-helical configuration One interpretation of these data is that the first hydrophobic region functions as a signal peptide and that the other four regions (M1-M4) serve as membrane spanning regions The size of KBP and the overall placement of the putative membrane spanning regions of KBP are similar to the size of known ligand-gated ion channel proteins and to the placement of putative membrane spanning regions of these proteins indicating that KBP has a general architecture similar to that of the chemically gated ion channels If KBP resembles ligand-gated ion channels, the N and C termini are probably located extracellularly This assignment is supported by the presence of putative N-glycosylation sites at positions 81 and 421, in the putative N- and C-terminal extracellular regions, and by the presence of putative phosphorylation sites

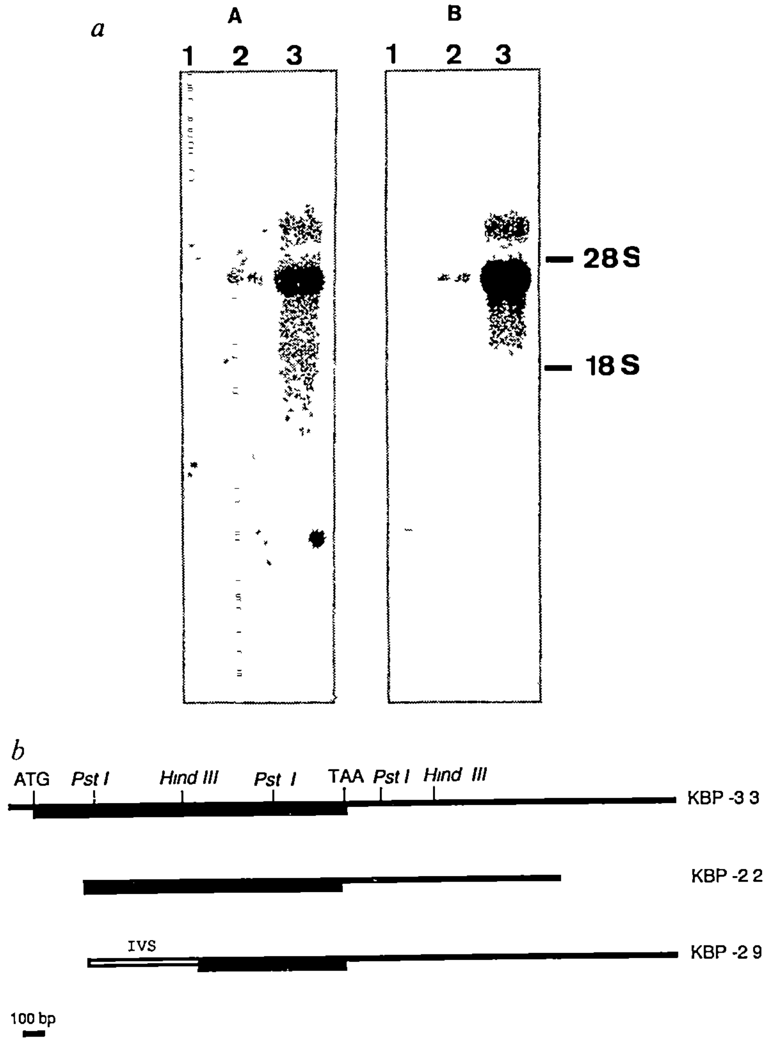
FIG 1 DNA sequence and deduced amino-acid sequence of the chick cerebellar kainate binding protein. Nucleotides are numbered at left and amino acids above the sequence The first in-frame stop codon in the 5′ untranslated sequence and the stop codon at the end of the coding region are labelled with asterisks Amino-acid numbering is from the first residue of the mature N-terminal sequence as established by direct N-terminal sequencing of the kainate binding protein The presumptive signal peptide sequence is indicated by negative numbering Peptide sequences determined chemically are denoted by solid lines and uncertain or unidentified residues by broken lines Signal peptide cleavage site is indicated by arrow The proposed membrane-spanning hydrophobic sequences are indicated by double lines (M1-M4) The putative extracellular N-glycosylation sites are labelled with two dots and the putative intracellular phosphorylation sites by a solid bar

METHODS The cDNA inserts of positive phages were subcloned into Bluescript phagemid pKS vectors (Stratagene) and sequenced by the dideoxy chain termination method[30] The sequence presented is combined from all cDNAs and both strands were analysed The 3′ untranslated regions of the cDNA clones beyond the *Pst*I site were not sequenced completely on both strands and are not shown



IG 2 Molecular cloning of the KBP cDNA *a*, Northern blot nalysis of chick RNA with oligodeoxyribonucleotide oligo-(dT) robe IV corresponding to peptide IV (panel A) and with cloned BP-2 2 cDNA (panel B) Line 1, liver, line 2, cerebrum, line 3, erebellum *b*, cDNA clones and partial restriction map All DNAs have their cognate 3′ poly-A sequences The 3′ ntranslated region of KBP-2 2 beyond the *Hind* III site is ifferent from KBP-3 3 and KBP-2 9, probably as a result of lternate 3′-end processing The open reading frame of KBP-9 was truncated at its 5′ side, probably as a result of complete splicing Solid box, protein coding region, IVS, resumed intervening sequence

/IETHODS Standard recombinant DNA methods were as lescribed[25] Based on the sequence of peptide IV, the oligo-dT) 5′-AARGCGTAGTTGSWCTCCAT-3′ (where R=A or G, S=C r G, W=A or T)[26] was synthesized (probe IV) and labelled o high specific radioactivity with [γ-^{32}P]ATP[27] Total RNA was solated[28] from adult chick tissues, 25 μg per line was electrophoresed on a 1% formaldehyde agarose gel, blotted on itrocellulose membrane (Hybond-C, Amersham) and hybridized overnight with the radiolabelled oligo-(dT) probe at 37 °C n 5×SSPE (1×SSPE contained 0 18 M NaCl, 0 01 M sodium hosphate, 1 mM EDTA, pH 6 8) as described[27] The high stringency wash was at 37 °C in 0 5×SSPE for 1 h Antisense robe I based on peptide I sequence was synthetized as an oligonucleotide mixture 5′-TAIGTIACIACIAGIACRTGRTCICAIC-QCTTRTTC-3′ (where I=inosine, Q=G or T and R=A or G), nd radiolabelled as above To isolate KBP cDNAs, an oligo-dT)-primed cDNA library in phage λgt-10 (ref 29) was constructed from cerebellar poly(A)$^+$-RNA of hatching chicks Double-stranded cDNA was synthesized, fitted with *Eco*RI inkers, and cDNAs were size fractionated on 1% agarose gel Fragments larger than 1 5 kb were isolated and ligated with *Eco*RI cut λgt-10, resulting in 150,000 independent ecombinants of which at least 50% carried inserts The ibrary was amplified and ~160,000 phages screened with robe IV as described above, positives were rescreened with robe I resulting in isolation of KBP-2 9 and KBP-2 2 clones A screen of 300,000 phages, under high stringency conditions, with the 0 8 kb *Pst*I-*Pst*I and 0 1 kb *Eco*RI-*Pst*I fragments derived from the 5′ end of KBP-2 2, led to the isolation of the clone KBP-3 3

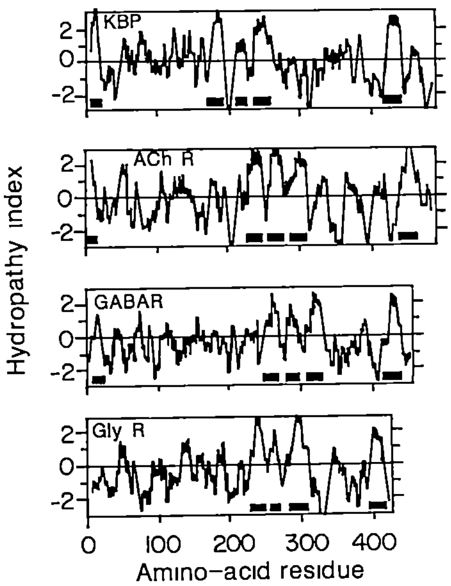


FIG 3 Structural similarity of the KBP to subunits of ligand-gated ion channels Hydropathy profiles computed according to Kyte and Doolittle[31], averaged over a window of 9 residues and plotted with a 1-residue interval Solid box, putative signal peptide and membrane spanning regions AChR, α2 chick acetylcholine receptor subunit[32], GABA R, γ-amino-butyric acid receptor α subunit[15], Gly R, glycine receptor[16]

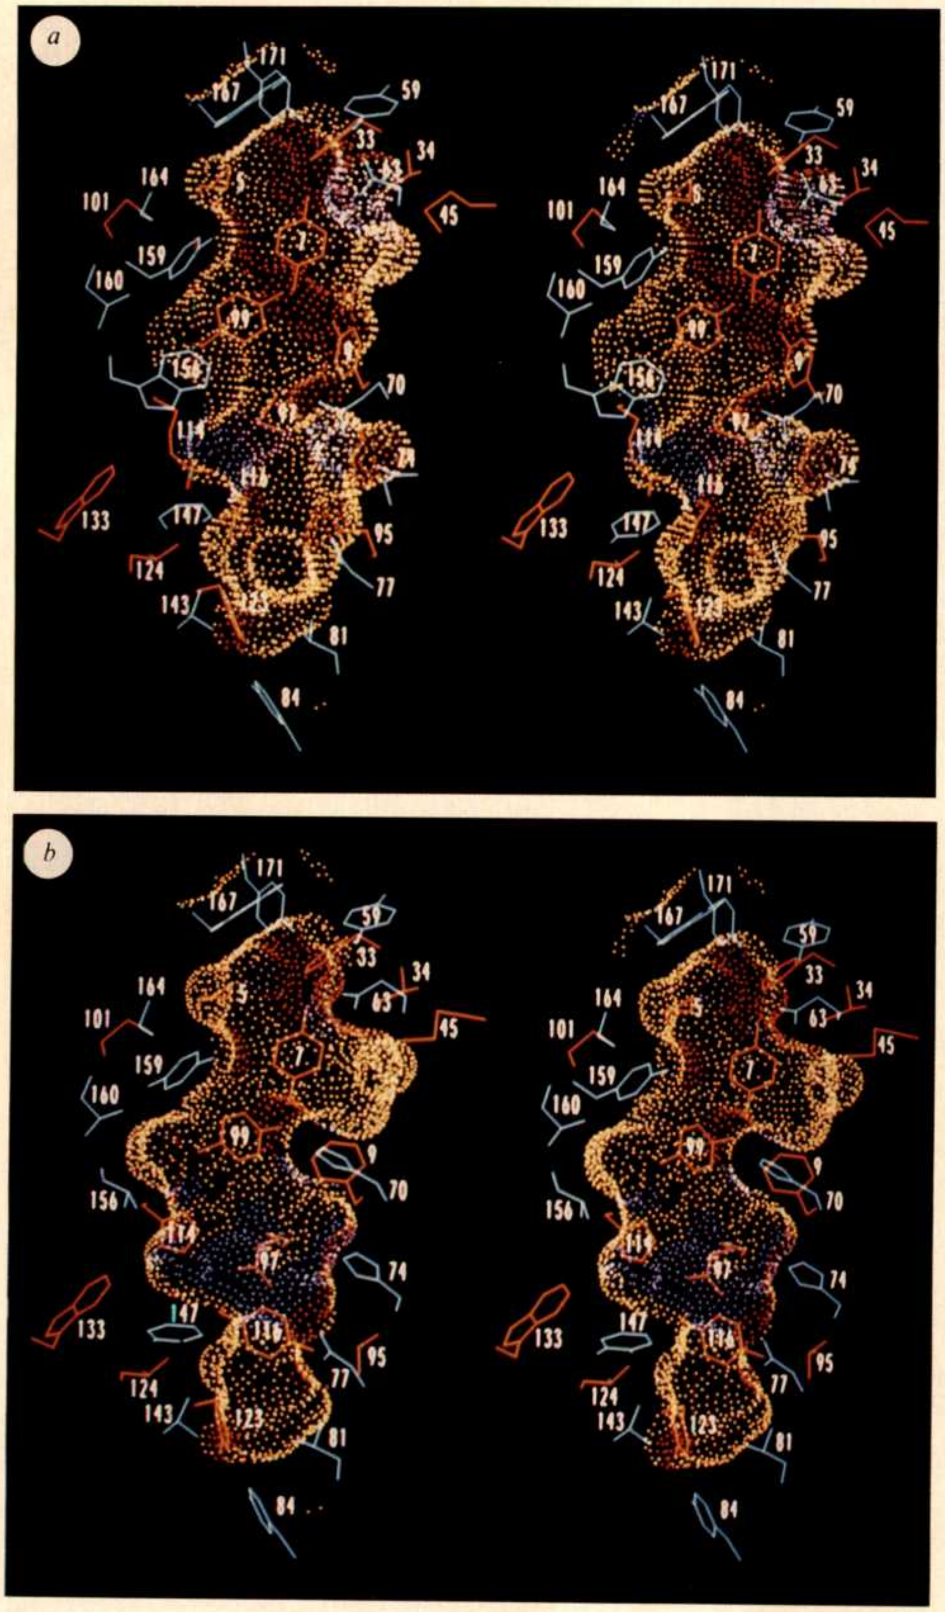
at positions 357 and 385, in the putative intracellular region between M3 and M4

Further analysis of KBP structure shows the presence of features compatible with channel function, particularly in its putative M2 transmembrane segment Indeed, the M2 domain of the various nicotinic acetylcholine receptor (AChR) subunits[14], which is essential to channel function[21-23], contains polar uncharged residues and is preceded by hydrophilic negatively charged residues Similar features in the equivalent region of KBP are observed, indicating, only by analogy, a possible role in ion permeation As mentioned above, KBP also contains potential phosphorylation sites, a finding consistent with the reported modulation of kainate-gated currents by protein kinase[24] If indeed, KBP forms part of an ion channel, its sequence does not display the homologies that have been used to group the various chemically gated ion channels in a single family The structure of KBP must therefore reflect its idiosyncratic properties, one of which is its unusually high density in the cerebellum and exclusive presence on Bergmann glia (ref 12 and P Somogyi, N Eshhar, V I T & J D Roberts, unpublished observations) Although its function is not yet known, its localization on Bergmann glial membranes surrounding the parallel fibre—Purkinje cell glutamatergic synapse indicates a role in modulation of synaptic efficacy Of relevance are our recent findings that isolated Bergmann glial cells in culture display high levels of KBP, depolarize in response to kainate and release GABA (γ-aminobutyric acid) (ref 12 and A Ortega and V I T, unpublished observations) The structural data presented here, together with the above observations, indicate therefore that KBP may be a subunit of a glial subtype of kainate receptor/cation channel ☐

provides the basis for allele-specific nonresponsiveness to certain immunological challenges[10,11,15,16]. Here we report the structure of HLA-Aw68 refined to a resolution of 2.6 Å, which when compared with the 2.7 Å resolution structure of HLA-A2 (M.A.S. *et al.*, manuscript in preparation, and ref. 17) suggests mechanisms for both the broad specificity and the allelic selectivity of peptide binding.

The structure of papain-solubilized HLA-Aw68 was determined and refined to 2.6-Å resolution (see ref. 18 for details) from orthorhombic crystals isomorphous to HLA-A2 crystals[19]. The overall structure, excluding the 13 amino-acid differences, is very similar to that of HLA-A2 refined to high resolution from both monoclinic crystals (2.7 Å; M.A.S. *et al.*, manuscript in preparation) and orthorhombic (2.5 Å) crystals[17]. Figure 1b shows the α-carbon backbone of HLA-Aw68 overlaid on the coordinates of the 2.7 Å resolution monoclinic crystal structure of HLA-A2 and lists root mean square (r.m.s.) deviations in coordinates between domains of the two structures. The average deviations are within the expected experimental error in the coordinates of these structures (Fig. 1*b*, legend).



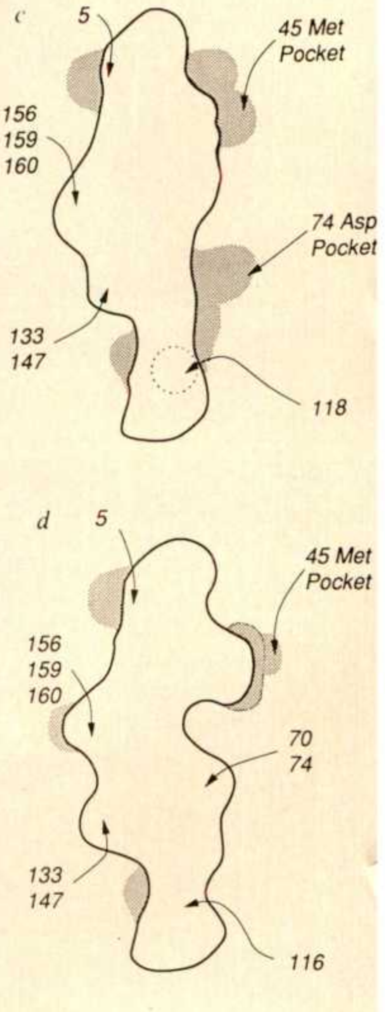


FIG. 3 Top view, comparison of binding site of HLA-Aw68 with HLA-A2. Stereograms show solvent contact surfaces of the clefts coloured by side-chain atom type: red, oxygen; blue, nitrogen; yellow, carbon; purple, sulphur. Side chain colours indicate secondary structure: red side chains, β-sheet; blue side chains, α-helix. *a*, HLA-Aw68 shows prominent new pockets near positions 74 and 116 and a ridge at positions 156 and 70. *b*, HLA-A2 shows Arg 97, Tyr 116, and His 74 filling the pockets. Both clefts have a pocket at 45. *c*, *d* Schematic outline of HLA-Aw68 (*c*) and HLA-A2 (*d*) cleft with pockets labelled. *a*, *b*, Constructed with HYDRA (R. Hubbard, unpublished) and surfaces were calculated using the program MS (ref. 29). Single-letter amino-acid code.

be present but that the Asp 74 pocket would probably be blocked by Arg 97 and Tyr 116 (as in HLA-A2), possibly explaining why one HLA-A2-specific peptide antigen also interacts with HLA-Aw69 (ref. 23).

Comparison of the three-dimensional structures of HLA-Aw68 and HLA-A2 demonstrates how different pockets or subsites within the cleft of the class I histocompatibility glycoproteins are produced by substitutions at positions of amino-acid polymorphism (compare Fig. 3*c* and *d*). The difference between these two allele products is typical of MHC allelic diversity, and so the same degree of structural change in pockets and subsites should be observed for other alleles. In the case we have described, polymorphism results in limited local structural changes; the backbone structure is generally not altered (Fig. 1*b*), and residues identical in both structures remain essentially unperturbed[18]. The observed effects of polymorphism were on the shape (for example, intrusions and ridges) an charge-distribution of the antigen-binding site, and on som local pockets, resulting in changes in their specificity and i their distribution in the site. These structural changes provid the basis for allelic specificity in peptide affinity[11,15,16] and th resultant non-responsiveness (and possibly hyper-responsiveness) to certain immunological challenges[10]. Because amino acid side chains from antigenic peptides could bind in thes pockets, peptides binding to one MHC allelic product coul then have a particular pattern of side chains[24,25] to fit the pockets Moreover, because the affinity of antigenic peptides fo individual histocompatibility glycoproteins may depend on onl a few of an antigenic peptide's side-chains fitting into a subse of the available pockets[26,27], a broad range of peptides coul be accommodated by the various combinations of filled an empty pockets. □

ACKNOWLEDGEMENTS. We thank Anastasia Haykov for technical assistance, Ted Jardetzky and Peter Parham for comments on the manuscript, and acknowledge support from the NIH and Howard Hughes Medical Institute. We also thank Drs Dean Mann (NIH), D. Michael Strong and James Wood (US Nava Research Unit) and Don Giard (MIT Cell Culture Facility) for provision of cells. Coordinates of HLA-Aw68 have been deposited in the Brookhaven Protein Data Bank (Accession no. 2HLA).

Limited receptor repertoire in a mycobacteria-reactive subset of $\gamma\delta$ T lymphocytes

THE physiological role of lymphocytes bearing the $\gamma\delta$ T-cell receptor (TCR) is still unclear. A function for a subset of these cells, however, is inferred from the finding that certain $\gamma\delta$ chain-bearing lymphocytes are stimulated in a receptor-dependent fashion by mycobacterial antigens[1–5]. We found that hybridomas derived from such cells in newborn murine thymus not only responded to mycobacterial purified protein derivative (PPD), but also exhibited an apparent autoreactivity[1]. In neither response was haplotype-specific major histocompatibility (MHC) restriction demonstrable. To investigate the nature of antigen recognition by these $\gamma\delta^+$ cells, we sequenced the γ- and δ-chains from 28 PPD-reactive hybridomas, and found that a specific γ-chain, together with one of a limited set of δ-chains, was needed to generate the PPD specificity. The reactive $\gamma\delta$ pairs exhibited considerable junctional diversity, which may act to produce differences in the fine specificities of the responding cells.

The TCR proteins from several PPD-reactive $\gamma\delta$ T-cell hybridomas[1] were compared with those from a collection of non-PPD-reactive $\gamma\delta$-hybridomas[1] by SDS-PAGE (Fig. 1, and data not shown). Most of the PPD-reactive hybridomas shared a δ-chain (the upper band of the receptor doublet) that was not frequently found among the nonreactive population (see also ref. 1). Although γ-chains showed a wider variability in relative molecular mass (M_r) than did δ-chains, all of the PPD-reactive and two of the nonreactive hybridomas possessed a γ-chain of the same M_r (39,000; the lower band of the receptor doublet). The size of this γ-chain indicated that it contained Cγ4 segment (ref. 6). Using a $V\gamma 1$-$C\gamma 4$ combination of oligonucleotide primers, polymerase chain reaction (PCR) amplification products were generated from the messenger RNA of all 28 of the PPD-reactive hybridomas and from 7 of the 25 non-PPD-reactive hybridomas. Sequence analysis revealed an in-frame $V\gamma 1JC\gamma 4$ transcript[7] (Fig. 2*a*) in all of the PPD-reactive hybridomas and only two of the non-PPD-reactive hybridomas. There did not seem to be selection for a particular *VJ* junctional sequence among the PPD-reactive hybridomas (Fig. 2*b*).

Based on our previous analysis, δ-chain gene oligonucleotides were designed that would amplify the $V\delta 6.1$ gene segment ($V\delta m23$ in refs 1 and 8), as well as the closely related $V\alpha 7$ and $V\delta 6$ gene family members[8–12]. Amplification products were generated with these oligonucleotides from 25 of the PPD-reactive and 3 of the non-PPD-reactive hybridomas. Sequence analysis revealed the use of two different *V* region gene segments (Fig. 2*a*). One was identical to the previously described $V\alpha 7.1$ (ref. 10). We have designated this $V\delta$ gene segment $V\delta 6.3$. The partial sequence obtained from the other *V* gene segment was identical to that previously described for the plasmid pλ12 member of the $V\delta 6$ family[13]. The predicted junctional amino acids for all of the $V\delta 6$ chains are listed in Fig. 2*b*, with the three non-PPD-reactive hybridomas indicated by asterisks. All of the $V\delta 6.3$ and $V\delta 6$ ($p\lambda 12$)-expressing hybridomas used the $D\delta 2$ and $J\delta 1$ gene segments, as do most $\gamma\delta$ T cells[8,11,14,15]. Characteristic of adult (as opposed to fetal) $\gamma\delta$ cells[11,14], $D\delta 1$ sequences were present in two of the hybridomas (BNT-9.12 and BNT-21.32), each in a different reading frame. This, and the presence of substantial

N region diversity in most of the PPD-reactive hybridomas, indicate that these cells appear relatively late in ontogeny[11]. All three different reading frames of the *Dδ2* gene segment could be used with retention of PPD specificity. Also, expression of different *N* region-encoded amino acids did not abolish the reactivity.

In both the δ- and the γ-chain, there were no apparent differences between the junctional regions in PPD-reactive versus non-PPD-reactive hybridomas that could account for the difference in reactivity. Instead, PPD-reactivity seems to result from the pairing of a Vγ1JCγ4 chain with a Vδ6-bearing chain. Twenty-five of the twenty-six hybridomas having this in-frame *V* gene combination exhibited PPD-reactivity; it is not yet clear why the remaining hybridoma (BNT-11.54) was nonreactive. Thus, whereas specificity for both the antigen and the presenting molecule seems to be encoded by the germline *V* gene segments, the diversity seen in the VD and VDJ joints of reactive hybridomas could serve simply to fine tune the response.

We next attempted to identify the *Vδ* gene segments used in the three *Vδ6*⁻ but PPD-reactive hybridomas (BNT-21.2, 41BNT-24 and 41BNT-117). Based on previous hybridization data[1], we performed PCR analysis with a *Vα2* oligonucleotide. We found that 41BNT-117, as well as two of the non-PPD-reactive hybridomas, possessed an in-frame transcript containing a new *Vδ* gene, which we have designated *Vδ8*. Both the nucleotide sequence and predicted corresponding amino-acid sequence of *Vδ8* (Fig. 3*a* and *b*, respectively) are >90% identical to those of members of the *Vα2* gene family. The Vδ8⁺ PPD-reactive hybridoma expressed an in-frame Vγ1JCγ4 transcript, whereas the two non-reactive Vδ8⁺ hybridomas did not.

A summary of *Vγ* and *Vδ* gene segment use in the 28 PPD-reactive and 25 non-reactive hybridomas is given in Table 1. The absolute requirement for the Vγ1JCγ4 chain in the PPD-reactive hybridomas is conspicuous. Note that the *Vγ2* gene, although nearly 90% identical to *Vγ1* at the predicted amino-acid level[7], was never found to encode the γ-chain expressed

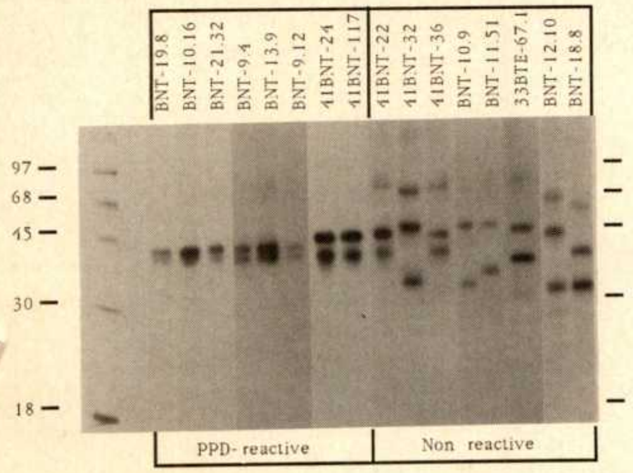

FIG. 1 Examination of surface TCR on γδ hybridomas by SDS-PAGE under reducing conditions. Hybridomas were generated and tested for antigen reactivity as previously described[1,27]. Representatives from both the PPD-reactive and the non-reactive collections are grouped accordingly. Bands corresponding to M_rs of >50,000 (50K) are residual nonreduced heterodimer.

METHODS. Cell-surface radioiodination of T-cell hybridomas was performed using Iodogen (Pierce, Rockville, Illinois) as described previously[28]. Cell lysates were prepared by detergent lysis using 1% digitonin[29]. Immunoprecipitations of the cell lysates were performed as described previously using the anti-CD3 monoclonal antibody HMT3-1 (R.T.K. *et al.*, manuscript in preparation) with protein A-Sepharose (Sigma)[30]. The immunoprecipitates were solubilized by boiling in Laemmli sample buffer[30] containing 0.01 M iodoacetamide, and electrophoresed on a SDS-PAGE gel (10% polyacrylamide). After electrophoresis, the gel was stained, destained, dried and autoradiographed for 18 h. Using the autoradiograph to localize the γδ heterodimer, each γδ band was excised from the dried gel and rehydrated in Laemmli sample buffer containing 5% 2-mercaptoethanol for 1–2 h. The gel slices were loaded onto a second SDS-PAGE gel (10% polyacrylamide) and electrophoresed to resolve the γ- and δ-subunits. The autoradiographs were developed after 3–5-days exposure. The positions of M_r protein standards ($M_r \times 10^{-3}$) are indicated on the left.

FIG. 2 *a*, Predicted amino-acid sequences encoded by the *Vγ1* and *Vδ6* gene segments (single-letter amino-acid code). Nucleotide sequences are identical to those previously published for *Vγ1* (ref. 6), *Vα7.1* (ref. 10) and *Vδ6(pλ12)* (ref. 12). Vδ6.3 and Vδ6(*p*λ12) have 69% amino-acid identity; the *Vδ6.3* gene segment is more closely related to the *Vδ6.1* (refs 8, 12; 86% amino-acid identity) and *Vδ6.2* (ref. 12; 97% amino-acid identity) family members. *b*, Predicted amino-acid sequences of the V–J junctional regions of the δ- and γ-chain mRNA found in the 28 Vδ6⁺ hybridomas. Hybridomas are from the 'BNT' collection (ref. 27; for example, BNT-9.12) unless otherwise noted. Hybridomas marked with an asterisk do not demonstrate PPD reactivity. No γ-chain junctional sequence is shown for those hybridomas which do not possess a functional *Vγ1JCγ4* transcript (BNT-18.8 and BNT-13.13). This γ-chain gene is not rearranged in the BW fusion line[14]. All clones bearing identical amino-acid sequences in the junctions were identical at the nucleotide level as well.

METHODS. RNA was isolated as previously described[31]. PCR amplification and sequence analysis of the amplified products was performed as previously described[32] using the following oligonucleotide primers (5′ to 3′): 5′*Vα7–Vδ6* external, GGATCTAATGTGGCCGAGA or GGATCTAATGTGGCCCAGA (amino-acid position, −4 to +3); 5′*Vα7* internal, AAGTGATTCAGGTCTGGTCA (amino-acid position, +3 to +9); 5′*Vδ6* internal, AGAAAGTGACTCAGGTCCAG (amino-acid position, +2 to +8); 5′*Cδ* external (antisense), ACAAGCAACATTTGTTCCAT (amino-acid position, +8 to +15 of *Cδ*); 5′*Cδ* internal (antisense), TTTTCATGATGAAACAGAT (amino-acid position, +15 to +21 of *Cδ*); 5′ *Vγ1* external, GGGCTTGGGCAGCTGGAGCA (amino-acid position, −3 to +4); 5′ *Vγ1* internal, AGTATCTAATATATGTCTCA (amino-acid position, +1 to +7); 5′ *Cγ4* external (antisense), GAAGGAAGGAAAATAGTAGG (amino-acid position, +12 to +18 of *Cγ*); 5′ *Cγ4* internal (antisense), GGAGAAAAGTCTGAGTCAGT (amino-acid position, +4 to +10 of *Cγ*).

FIG. 3 Nucleotide sequences (*a*) and corresponding predicted amino-acid sequences (*b*) of *Vα2.1* (isolated from C57BL/Ka (ref. 10) but identical to C57BL/10 (M.P.H., D. DiGiusto and E.P., unpublished observation)), *Vα2.2* (isolated from BALB/c mice; M. Zauderer, personal communication) and *Vδ8* (designated *Vδ7* in ref. 1 just before a different *Vδ7* sequence was described in ref. 14; isolated from C57BL/10 and C57BL/6 strain mice).

METHODS. As in Fig. 2, with the addition of the following *Vα2* oligonucleotides (5′ to 3′): 5′ *Vα2* external, AGCAGCAGGTGAGACAAAGT (amino-acid position, +1 to +7); 5′ *Vα2* internal, CCCCAATCTCTGACAGTCTG (amino-acid position, +8 to +14).

in any of the PPD-reactive cells. But the *Vγ2* gene segment has only been found to rearrange the *JCγ2* gene cluster, which differs considerably from the *JCγ4* gene cluster to which the *Vγ1* gene segment generally rearranges. Thus the use of *Vγ1JCγ4* can be dictated as much by the need for the *JCγ4* gene segments as by the need for the *Vγ1* gene segment. It is clear that not all *Vδ* gene segments are permissive for PPD-reactivity, but Table 1 does include at least four that are: *Vδ6.3*, *Vδ6* (pλ12), *Vδ8* and at least one more unidentified *Vδ*.

The *Vδ6*-expressing hybridomas that we analysed represent all of the *Vδ6*-expressing surface receptor-bearing cells that we have so far generated; they are all derived from newborn thymus and are not a subset selected on the basis of reactivity. The apparent 'predisposition' of these cells to express a specific γ-chain gene (26 out of 28 express *Vγ1JCγ4*, see Table 1) indicates that this is another instance of restricted γ-δ-chain pairing[12,15,16]. In support of this observation, a *Vδ6*-bearing hybridoma generated by McConnell *et al.*[12] expressed a Vγ1Cγ4 protein, and several T-cell lines producing Vδ6 mRNA also expressed the *Vγ1Cγ4* gene product. The tendency for these two chains to be associated with one another could simply be due to physical constraints, or to the ontogenetic timing of *V* gene rearrangements. A third possibility, supported by the fact that the frequently appearing Vδ6–Vγ1JCγ4 combination produces a defined antigen specificity, is that the limited pairing seen is due to a selective pressure to generate this antigen specificity (that is, 'functional constraints').

Finally, the PPD-reactivity of most hybridomas expressing Vγ1JCγ4 is reminiscent of the ability of certain *Vβ* gene segments to confer reactivity to *Mls* gene products or staphylococcal enterotoxins (the proposed 'superantigens') in 80–90% of the $\alpha\beta^+$T-cells in which they are expressed[17-23]. Such $\alpha\beta^+$T-cell responses are unusual in that they seem to involve recognition of relatively nonpolymorphic determinants of MHC gene products. Some $\gamma\delta^+$ T-cell responses involve specific MHC class I molecules (refs 24, 25), or *TL* (ref. 24) or *Qa* (ref. 26) gene products, but the presenting molecule for mycobacterial antigens has so far not been identified. This molecule seems to be relatively nonpolymorphic in some instances[1,3] but not in others[4,5]. It remains to be seen whether the use of only one *Vγ* gene in all of the PPD-reactive hybridomas indicates that PPD represents a superantigen for these cells, or that the cells all recognize one particular antigenic epitope or presenting molecule, but the observations presented here should be useful in elucidating the nature of antigen recognition by the γδTCR. □

TABLE 1 Summary of *Vγ* and *Vδ* gene usage in PPD-reactive and non-reactive $\gamma\delta^+$ T-cell hybridomas

Vγ→ Vδ↓	PPD-reactive		Non-reactive	
	Vγ1Jγ4	Other *Vγ*	*Vγ1Jγ4*	Other *Vγ*
Vδ6.3	21	0	1	1
Vδ6 (*p*λ*12*)	4	0	0	1
Vδ8	1	0	0	2
Vδ1	0	0	0	10
Other *Vδ*	2	0	2	8
Total	28	0	3	22

Vγ gene usage is classified as *Vγ1Jγ4* or non-*Vγ1Jγ4* as determined by sequencing of PCR amplification products (see Fig. 2 legend). The use of *Vδ6.3*, *Vδ6*(*p*λ*12*) or *Vδ8* was determined first by RNA hybridization analysis[1] and then by sequencing of PCR amplification products (see Fig. 2 legend). The use of *Vδ1* was determined by RNA hybridization analysis only[1], therefore not all may be rearranged in frame. Unidentified *Vδ* genes are grouped as 'other *Vδ*'.

Note added in proof. A small portion of a probable *Vδ*, isolated from a thymocyte circular DNA library[33], is closely related to the *Vδ8* gene we describe here.

The colony stimulating factor-1 receptor associates with and activates phosphatidylinositol-3 kinase

COLONY stimulating factor-1 (CSF-1) is a lineage-specific growth factor required for proliferation and survival of mononuclear phagocytes and their precursors. The CSF-1 receptor belongs to a family of ligand-activated protein-tyrosine kinases. Activation of the platelet-derived growth factor receptor, but not the CSF-1 receptor, leads to an increase in phospholipase C activity and a subsequent elevation in intracellular calcium. Recent studies have shown that a novel phosphoinositol (PtdIns) kinase, termed PtdIns-3 kinase, is stimulated by the platelet-derived growth factor receptor and certain oncogenes in the protein-tyrosine kinase family. PtdIns-3 kinase phosphorylates the D-3 hydroxyl position of the inositol ring of PtdIns, and its products do not participate in the generation of the second messenger inositol 1,4,5-trisphosphate ($Ins(1,4,5)P_3$). Here we report that addition of CSF-1 is followed by activation of PtdIns-3 kinase in a macrophage cell line (P388 D1), which contains CSF-1 receptors, and in BALB/c fibroblasts made to express the human CSF-1 receptor. Furthermore, we show that activation of the CSF-1 receptor results in the accumulation in intact cells of polyphosphoinositides phosphorylated at the D-3 position of the inositol ring. Thus activation of the CSF-1 receptor stimulates PtdIns-3 kinase activity, indicating a novel pathway for CSF-1 receptor-mediated signal transduction.

CSF-1 activity is mediated through a single class of high-affinity receptors[1-3]. The gene encoding the CSF-1 receptor (c-*fms*) is the normal cellular homologue of the v-*fms* oncogene and belongs to a family of structurally related transmembrane growth-factor receptors with ligand-activated protein-tyrosine kinase activity. Other members of this family include the receptor for platelet-derived growth factor (PDGF) and the c-*kit* gene product, the ligand for which is unknown. These receptors are unique among protein-tyrosine kinases in that their kinase domains contain an insert of 70–100 amino acids. Although the PDGF and CSF-1 receptors are structurally similar, there are differences in the cellular responses that follow their activation. For example, PDGF activates PtdIns turnover and increases intracellular calcium[4,5], whereas CSF-1 does not affect PtdIns turnover or cytosolic calcium in murine macrophages[6].

Recent studies have identified a unique PtdIns kinase activity associated with certain activated tyrosine kinases[7,8]. This PtdIns kinase, called PtdIns-3 kinase, physically associates with $pp60^{v\text{-}src}$ and polyoma middle T/$pp60^{c\text{-}src}$ complexes[9], and is also detected in antiphosphotyrosine immunoprecipitates from cells transformed with v-*src*, v-*fms* and v-*abl*, and in quiescent fibroblasts and smooth muscle cells after stimulation with PDGF[7,10,11]. PtdIns-3 kinase phosphorylates PtdIns at the D-3 position of the inositol ring of PtdIns to form a novel product, phosphatidylinositol 3-phosphate (PtdIns(3)P)[12].

We investigated whether PtdIns-3 kinase is activated in response to CSF-1. Human CSF-1 receptor was expressed in murine fibroblasts at $\sim 0.5\text{–}1 \times 10^4$ receptors per cell. Full-length complementary DNA clones for the human CSF-1 receptor gene and feline v-*fms* were introduced into recombinant retrovirus pLJ (ref. 13). BALB/c fibroblast cell lines expressing these constructs were generated by retroviral infection as previously described[14]. Immunoblot analysis was used to screen cells for *fms*-encoded proteins (Fms) and the expression of CSF-1 receptor protein was confirmed by [^{35}S]methionine labelling and immunoprecipitation with monoclonal anti-Fms antibodies. Fibroblasts make CSF-1, but no autocrine effect was observed because murine CSF-1 does not stimulate human CSF-1 receptor, although human CSF-1 stimulates human and murine receptors[15-17]. Therefore, no alterations of cell growth or serum requirements were detected in the c-*fms*-expressing cells.

PtdIns kinase activity was detected in immunoprecipitates of CSF-1-stimulated cells (Fig. 1). Confluent serum-starved BALB/c fibroblasts which express CSF-1 receptor were stimulated with human recombinant CSF-1, lysed and immunoprecipitated with anti-phosphotyrosine antibodies. The greatest production of phosphatidylinositol phosphate (PtdInsP) was observed when c-*fms*-expressing cells were stimulated with 20 ng ml^{-1} of human recombinant CSF-1 (results not

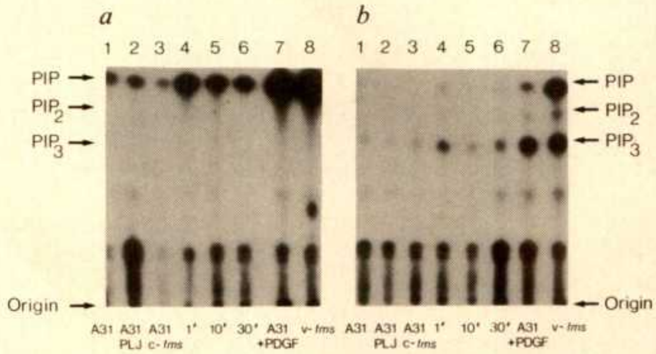

FIG. 1 Time course of CSF-1 dependent activation of PtdIns kinase in anti-phosphotyrosine immunoprecipitates. *a*, TLC analysis of products of lipid kinase assay of anti-phosphotyrosine immunoprecipitates using PtdIns as substrate: A31 parent BALB/c fibroblast cell line (lane 1); A31 cells transfected with the vector alone (lane 2); quiescent A31 fibroblasts expressing human CSF-1 receptor (lane 3); A31 cells expressing human CSF-1 receptor stimulated for 1,10 and 30 min with 20 ng ml^{-1} of human recombinant CSF-1 (lanes 4, 5 and 6); A31 cells expressing human CSF-1 receptor stimulated for 10 min with 10 ng ml^{-1} of recombinant PDGF-BB (lane 7); and v-*fms*-transformed fibroblasts (lane 8). Identification of the product was performed using commercial PtdInsP (PIP) as standard. The migration of the standards (visualized by iodine staining) are indicated by the arrows. Phosphoinositide formation in lanes 1–3 was identified as PtdIns(4)P after deacylation and HPLC analysis. *b*, TLC analysis of the products of lipid kinase assay of anti-phosphotyrosine immunoprecipitates using $PtdIns(4,5)P_2$ as substrate. Lanes are the same as in *a*. PtdIns and PtdIns(4)P contaminants in the commercial $PtdIns(4,5)P_2$ resulted in some formation of PIP and $PtdInsP_2$ (PIP_2). The migration of $PtdInsP_3$ (PIP_3) standard synthesized from polyoma middle T/$pp60^{c\text{-}src}$ immunoprecipitates is indicated by the arrow. METHODS. Confluent cultures of BALB/c fibroblasts were placed in serum-free DME medium supplemented with 1% BSA for 24 h to induce quiescence. Recombinant human CSF-1 (courtesy of S. Clark, Genetics Institute) was added to cells for indicated times (prime symbols denote min). Cells were lysed in a 25 mM HEPES buffer, pH 7.5, containing 137 mM NaCl, 1 mM EDTA, 200 μm sodium vanadate, 10% glycerol, 1% Nonidet P-40, 10 μg ml^{-1} aprotinin and 1 mM phenylmethylsulphonyl fluoride, and immunoprecipitated by incubation for 4 h with anti-phosphotyrosine monoclonal antibody linked to solid support as described by Frackelton *et al.*[24]. The immunoprecipitates were washed twice with each of the following: (1) ice-cold PBS; (2) 0.5 M LiCl and 0.1 M Tris buffer, pH 7.4; and (3) 0.1 M NaCl, 1 mM EDTA in 0.1 M Tris buffer, pH 7.4 (ref. 9). PtdIns kinase activity was assayed in the immunoprecipitates in the presence of 25 mM HEPES buffer, pH 7.4, and 10 mM $MgCl_2$. A mixture of 0.1 mg ml^{-1} PtdIns (*a*) or PIP_2 (*b*) and 0.1 mg ml^{-1} phosphatidylserine, dispersed by zonication in 25 mM HEPES buffer pH 7.4 and 1 mM EDTA, was added to the immunoprecipitates. The reaction was initiated by addition of 20 μCi of [γ-^{32}P]ATP and 100 μM ATP as previously described[12]. The products were separated by TLC in 1-propanol:acetic acid (2*N*) [65:35 (v/v)], visualized by autoradiography and identified by comparison with non-labelled standards.

---

‡ Present address: Department of Medicine, Howard Hughes Medical Institute, University California, San Francisco, California 94143, USA.

shown). This concentration of CSF-1 was used in all subsequent experiments, and is equivalent to 3,000 U ml^{-1} (1U is equivalent to 0.44 fmol); and is comparable to the amount of CSF-1 that elicits a maximal mitogenic response in murine macrophages which express a similar number of CSF-1 receptors[18,19]. Increased immunoprecipitable PtdIns kinase activity was detected within 1 min after addition of CSF-1 (Fig. 1*a*). No CSF-1-dependent PtdIns-3 kinase activity was detected when parent BALB/c fibroblasts or cells infected with the vector alone were used (results not shown). The PldIns-3 kinase activity detected in antiphosphotyrosine immunoprecipitates of PDGF-stimulated cells was fivefold higher than that detected in CSF-1-stimulated cells (lanes 5 and 7, Fig. 1*a*). These activities correspond to the relative abundance of each receptor. Antiphosphotyrosine immunoprecipitates of v-*fms*-transformed cells had elevated PtdIns-3 kinase activity in the absence of exogenous CSF-1 (lane 8, Fig. 1*a*).

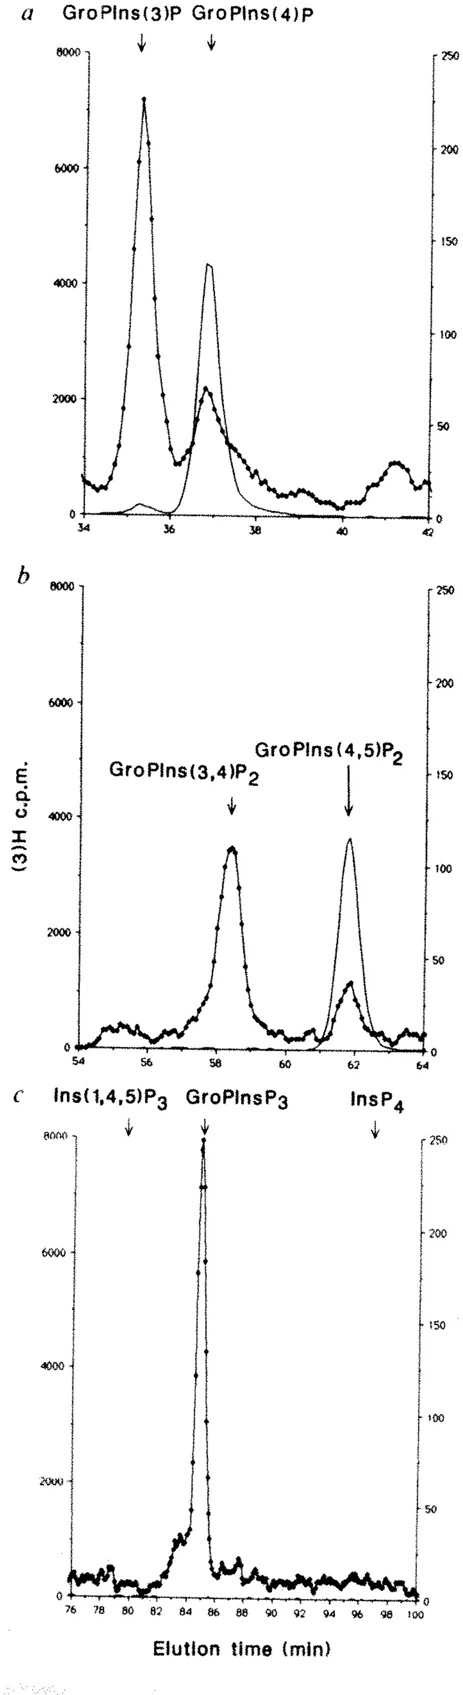

FIG. 2 HPLC identification of polyphosphoinositides generated from antiphosphotyrosine immunoprecipitates of CSF-1-stimulated cells. *a*, HPLC separation of the deacylated product of PtdIns kinase assay of anti-phosphotyrosine immunprecipitates from CSF-1-stimulated cell. The [^{32}P]PtdInsP was produced and deacylated with methylamine reagent as previously described[19]. Solid line represents [^{3}H]GroPIns(4)P standard. ■, Deacylated ^{32}P-labelled PtdInsP generated from fibroblasts which express human CSF-1 receptor after exposure to 20 ng ml^{-1} of human recombinant CSF-1 for 5 min. The migration position of GroPIns(3)P was determined from a parallel run of [^{32}P]GroPIns(3)P standard generated from middle T/pp60$^{c\text{-}src}$ immunoprecipitates. *b*, HPLC separation of the deacylated product generated as above except using PtdIns(4)P as substrate. Solid line represents [^{3}H]GroPIns(4,5)P$_2$ standard. Closed squares represent deacylated ^{32}P-labelled PtdInsP$_2$. The migration position of the GroPIns(3,4)P$_2$ was determined from a parallel run of [^{32}P]GroPIns(3,4)P$_2$ standard generated from middle T/pp60$^{c\text{-}src}$ immunoprecipitates. *c*, HPLC separation of the deacylated product generated as above, except using PtdIns(4,5)P$_2$ as substrate. Closed squares represent deacylated ^{32}P-labelled PtdInsP$_3$. Arrows indicate the migration position from a parallel run of [^{3}H]Ins1,4,5P$_3$ and [^{3}H]Ins1,3,4,5P$_4$ standards (NEN), and the position of [^{32}P]GroPInsP$_3$ generated from middle T/pp60$^{c\text{-}src}$ immunoprecipitates.

METHODS. Deacylated phospholipids were suspended in 400 μl H$_2$O with appropriate standards and separated by anion exchange HPLC using a Partisphere Sax column with a gradient from 0 to 1.0 M (NH$_4$)$_2$HPO$_4$ (pH 3.8) developed over 130 min[11]. Isotope detection was performed using an on-line continuous flow scintillation detector (Radiomatic Instruments) which separates ^{3}H, ^{32}P counts, and a parallel reading of UV channel for detection of non-labelled ADP and ATP standards.

Antiphosphotyrosine-antibody immunoprecipitates from CSF-1-stimulated cells also had lipid kinase activities which used phosphatidylinositol 4-phosphate (PtdIns(4)P) and phosphatidylinositol 4,5-biphosphate (PtdIns (4,5)P$_2$) as substrates. Figure 1b presents the results of an experiment in which PtdIns (4,5)P$_2$ was used as a substrate. The product of this reaction migrated with phosphatidylinositol trisphosphate (PtdInsP$_3$) standard on TLC. A significant increase in PtdIns(4,5)P$_2$ kinase activity was detectable within 1 min (the decrease in activity seen at 10 min in Fig. 1*b*, lane 5, was not reproduced in three other experiments). Elevated PtdIns(4,5)P$_2$ kinase activity was also detected in immunoprecipitates from v-*fms*-transformed cells and in BALB/c control cells stimulated with PDGF. When PtdIns(4)P was used as a substrate, a PtdIns P$_2$ was produced with a similar CSF-1 dependence (data not shown). HPLC identification of the products obtained in these reactions is shown in Fig. 2. The lipids were deacylated and identified by comparison of their HPLC-migration positions with those of standards: [^{32}P]PtdIns(3)P, [^{32}P]PtdInsP$_2$ and [^{32}P]PtdInsP$_3$ standards were synthesized using middle T/pp60$^{c\text{-}src}$ immunoprecipitates[19]; [^{3}H]PtdIns(4)P and [^{3}H]PtdIns(4,5)P$_2$ standards were from a commercial source. No D-3 phosphorylated polyphosphoinositides were detected in control lanes. The deacylation product of the PtdInsP which was produced by antiphosphotyrosine immunoprecipitates from CSF-1-stimulated cells comigrated with glycerophosphoinositol 3-phosphate (GroPIns(3)P); the deacylated PtdInsP$_2$ comigrated with glycerophosphoinositol 3,4-bisphosphate (GroPIns(3,4)P$_2$) standard, and the deacylated PtdInsP$_3$ comigrated with glycerophosphoinositol-trisphosphate (GroPInsP$_3$) standard. Thus, CSF-1 receptor seems to stimulate the same lipid kinase activities as those associated with middle T/pp60$^{c\text{-}src}$ and PDGF receptor[19].

A monoclonal antibody which specifically recognizes the N-terminal domain of both *c-fms* and v-*fms* proteins was used to investigate whether PtdIns-3 kinase directly associates with the CSF-1 receptor. Increased phosphorylation of PtdIns was detected in immunoprecipitates from CSF-1-stimulated cells when anti-Fms antibodies were used. HPLC analysis of the deacylated lipid showed that although some PtdIns(4)P was produced by the immunoprecipitates, the principal lipid was PtdIns(3)P. A similar result was detected using immunoprecipitates from v-*fms*-transformed cells (Fig. 3). These results indicate that PtdIns-3 kinase is physically associated with ligand-activated CSF-1 receptor and with v-Fms oncoprotein.

We also investigated the ability of CSF-1 to stimulate PtdIns-3 kinase in a cell line which expresses endogenous CSF-1 receptor. P388 D1 is a murine macrophage cell line which expresses 3.5×10^3 CSF-1 receptors per cell[2]. After addition of recombinant human CSF-1, an increase in PtdIns-3 kinase activity was detected in anti-phosphotyrosine immunoprecipitates (data not shown). Thus, activation observed with the transfected receptor is not merely a consequence of expression of the receptor in fibroblasts.

The polyphosphoinositides produced by PtdIns-3 kinase in immunoprecipitates from CSF-1-stimulated cells were also elevated in response to CSF-1 in intact cells. P388 D1 macrophage cells were starved of serum for 14 h and labelled with $^{32}PO_4^{3-}$ for 3 h. Analysis of deacylated phospholipids from starved murine macrophage cells showed small but detectable amounts of ^{32}P-labelled lipids which comigrated with deacylated PtdIns(3)P, PtdIns(3,4)P_2 and PtdInsP_3 standards. These lipids each represented, respectively, 3.2%, 0.7% and 0.2% of the ^{32}P label incorporated into PtdIns(4)P in the same HPLC analysis. This observation differs from results obtained from serum-starved fibroblasts and smooth muscle cells where no PtdIns(3,4)P_2 or PtdInsP_3 was detected[19], and could be due to the difficulty in synchronizing these macrophages into a G_0 state. Addition of human recombinant CSF-1 for 5 min resulted in a 70% increase in PtdIns(3,4)P_2, and a 300% increase in PtdInsP_3. The levels of these lipids declined but remained above control values at 30 min (Fig. 4). No CSF-1-mediated changes in the content of PtdIns(3)P were seen. Similar results were observed in smooth muscle cells[11] after addition of PDGF, suggesting that intracellular PtdIns(3)P levels do not change during mitogenic response.

The physiological significance of PtdIns-3 kinase remains to be determined. None of the products of this kinase are in the pathway for generating the Ca^{2+}-regulating second messenger, Ins(1,4,5)P_3, suggesting that these lipids provide signals independent of the conventional PtdIns turnover response. Evidence for the importance of PtdIns-3 kinase for growth and transformation is provided by studies of mutants for the polyoma middle T gene and mutants for the PDGF receptor gene. In most middle T gene mutants which are defective in cell transformation, PtdIns-3 kinase fails to associate with the middle T/pp60$^{c\text{-}src}$ complex[9,20]. Included in this group of transformation-defective genes are mutants in which the middle T protein associates with and activates the protein-tyrosine kinase activity of pp60$^{c\text{-}src}$, but fails to associate with or activate PtdIns-3 kinase. A similar phenotype has been observed for a mutant PDGF receptor in which 83 of the 100 amino acids in the protein-

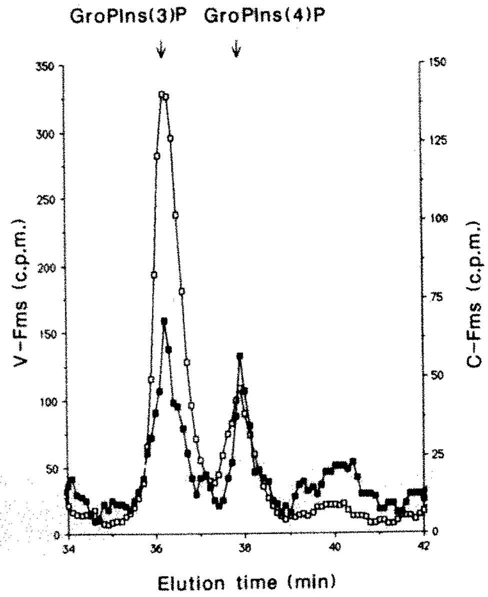

FIG. 3 HPLC analysis of the deacylated PtdInsP product produced by the anti-Fms immunoprecipitates of c-Fms expressing fibroblasts which were stimulated with CSF-1- and v-Fms-transformed cells. ■, Deacylated ^{32}P-labelled PtdInsP generated from immunoprecipitates of *c-fms*-expressing cells stimulated with CSF-1. □, Deacylated ^{32}P-labelled PtdInsP generated from immunoprecipitates of v-*fms*-transformed cells (no CSF-1 added). CSF-1-stimulated fibroblasts which express the CSF-1 receptor and v-*fms*-transformed cells were lysed, equalized for the amount of protein, and reacted with rat monoclonal anti-Fms antibody for 6 h. An anti-rat polyclonal antibody linked to a solid support (Cooper Diagnostics) was used as a second antibody. PtdInsP generated by immunoprecipitable PtdIns kinase was analysed as indicated in Fig. 2.

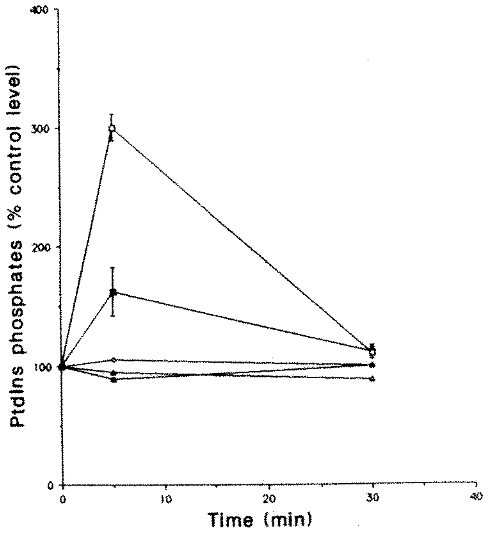

FIG. 4 Time course of the levels of polyphosphoinositides in intact murine macrophages after stimulation with CSF-1: *In vivo* levels of PtdInsP_3 (□); PtdIns(3,4)P_2 (■); PtdIns(3)P (△); PtdIns(4)P (◇) and PtdIns(4,5)P_2 (▲) are expressed as percentages of the control level. Each point represents three independent experiments. The error bars represent s.d. Murine macrophages were grown to confluency in RPMI, 10% FCS and deprived of serum for 14 h. Cells were washed with phosphate-free MEM supplemented with 1-glutamine and 1% BSA, and labelled for 3 h with 0.1 mCi $^{32}PO_4^{3-}$ ml^{-1}. The medium was removed, cells were rinsed with the same medium without $^{32}PO_4^{3-}$, and stimulated with 10 ng ml^{-1} human recombinant CSF-1 at time =0. At the end of the periods indicated, the medium was removed and 1 M HCl was added to the plate. Cells were gathered with the aid of a Teflon cell scraper and the phospholipids were extracted into methanol:chloroform (1:2, v/v)[11]. The phospholipids were deacylated as indicated in the legend to Fig. 2 and identified on HPLC by comparison with deacylated standards. Between 0.8 and 2×10^6 ^{32}P c.p.m. were used per HPLC run. In a typical experiment (1×10^6 c.p.m. injected into HPLC), the total counts incorporated at time zero were 177,206 for PtdIns(4)P, 219,936 for PtdIns(4,5)P_2, 5,818 for PtdIns(3)P, 1,252 for PtdIns(3,4)P_2, and 366 for PtdInsP_3.

tyrosine kinase domain insert are deleted[21,22]. This receptor retained PDGF-stimulated protein-tyrosine kinase activity, stimulated PtdIns turnover and calcium elevation, but did not associate with PtdIns-3 kinase and failed to mediate PDGF-dependent DNA synthesis. These results indicate that activation of PtdIns-3 kinase could be essential for the growth and transformation response of these genes. But transformation-defective mutants of middle T protein (ref. 23, and B.D. and T.R., unpublished observations) and of p60$^{v\text{-}src}$ (ref. 20) which retain wild type levels of PtdIns-3 kinase have been found, suggesting tha this activation alone is not sufficient for transformation. W have shown that the CSF-1 receptor has similar properties t the PDGF receptor with respect to activation of the PtdIns- kinase pathway, indicating that production of D-3 phosphory lated phosphoinositides could be critical for the growth-stimu lating activities of these two receptors.

RETINOIC acid has profound effects on vertebrate limb morphogenesis (refs 1–6, reviewed in refs 7–9), including in the mouse, where it can act as a teratogen generating phocomelia and bone defects[10–12]. A retinoic acid gradient[13–15], possibly amplified by a graded distribution of cellular retinoic acid-binding protein (CRABP)[16], could provide positional information across the antero-posterior axis of the chick limb bud. The discovery of nuclear retinoic acid receptors (RARs)[17–22] acting as retinoic acid-inducible enhancer factors (reviewed in refs 23, 24) provided a basis for understanding how retinoic acid signals could be transduced at the level of gene expression[25]. We have now used *in situ* hybridization to study the distribution of messenger RNA transcripts of the three murine receptors (mRARs) and CRABP during mouse limb development. Both mRARα and mRARγ transcripts, but not those for mRARβ, are present and uniformly distributed in the limb bud at day 10 post-coitum, whereas CRABP transcripts have a graded proximo-distal distribution, indicating that differential expression of CRABP, but not of mRARα or mRARγ, could participate in the establishment of the morphogenetic field. At later stages, mRARγ transcripts become specific to the cartilage cell lineage and to the differentiating skin and mRARβ transcripts are mostly restricted to the interdigital mesenchyme. CRABP transcripts, however, are excluded from regions expressing mRARγ and mRARβ. These results indicate that all three RARs and CRABP have specific functions during morphogenesis and differentiation of the mouse limb.

We synthesized ^{35}S-labelled antisense RNA probes from mRARα, mRARβ and mRARγ (ref. 21) and murine CRABP (ref. 26) complementary DNA clones, and hybridized them to serial sets of contiguous histological sections. Three stages of the mouse limb development were studied, corresponding to nondifferentiated limb buds (day 10 post-coitum (p.c.)), the appearance of precartilaginous blastemas (day 12.5 p.c.) and the beginning of ossification and digit separation (day 14.5 p.c.). Forelimb bud sections at day 10 p.c. showed that mRARγ (Fig. 1*a*, *b*) and mRARα (data not shown) transcripts were homogeneously distributed throughout the limb bud. The signal for mRARγ transcripts stopped at the proximal limit of the buds, whereas that for mRARα transcripts extended into adjacent tissues. mRARβ transcripts were detected only in the most proximal region of the limb buds and in the mesenchyme of the flank (data not shown). Whereas CRABP transcripts were abundant and uniformly distributed in posterior sections of the forelimb (Fig. 1*a*, R), there was a gradual proximal-to-distal increase in transcripts in more anterior sections (Fig. 1*a*, L; *b*), so that no labelling was seen in the proximal core of the bud, whereas it was maximal at the distal tip. No CRABP transcripts were detected in the ectodermal layer (Ec), except in the apical ectodermal ridge (AER), where only the most dorsal cells were repeatedly labelled, irrespective of their antero-posterior location (Fig. 1*a*–*c*). By contrast, both the AER and ectoderm were devoid of mRARγ transcripts (Fig. 1*c*). The immunohistochemistry study of Maden *et al.*[16] has similarly revealed a higher concentration of CRABP in the distal progress zone of the chick limb bud. Moreover, the existence of an antero-posterior gradient of CRABP in this zone, with opposite polarity to that of retinoic acid[13] has been reported[16]. We did not find an equivalent gradient of CRABP transcripts. Further studies are required to establish whether such a gradient of CRABP exists. The results described here, however, indicate that there could be a proximo-distal gradient of CRABP, which is maximal distally. This could create a gradient of free retinoic acid across the limb bud, which may be interpreted by the uniformly expressed mRARα or mRARγ, or both, at the time when positional information is to be specified.

By day 12.5 p.c., a remarkable segregation of the domains of expression of mRARγ and CRABP was apparent. Murine RARγ transcripts were proximally restricted to central precartilaginous blastemas (PB) of both forelimb (Fig. 1*d*) and hindlimb (Fig. 1*e*), and more homogeneously distributed in the distal undifferentiated mesenchyme of both limbs. By marked contrast, CRABP transcripts appeared to be excluded from the central PB and were most abundant in cells underlying the ectoderm

IG. 1 Detection of mRARs and CRABP transcripts in the developing murine limbs by gestational days 10 and 12.5 p.c. Bright-field views of selected section planes are shown in left panels for histological identification. The right and middle panels are dark-field views showing autoradiography signal (white grains) on contiguous sections hybridized with mRARs and CRABP probes, as indicated. Sections hybridized to CRABP probes were exposed half as long as all others. *a, b*, Two serial transverse sections across the forelimb buds of a 10-day-p.c. embryo. The section shown in *b* is more anterior than in that shown in *a*. Because the section plane is slightly biased, the left limb (L) is cut more anteriorly. Bar, 160 μm. *c*, Higher magnification of the distal region of the forelimb bud (including the AER as indicated) of a 10-day-p.c. embryo. Note that absence of labelling in the ectoderm (Ec) with both probes (the short white arrows point to the same Ec position in the dark-field views as the black arrow in the bright-field view), and the selective labelling of the dorsal part of the AER with the CRABP probe (curved arrow). Bar, 50 μm. *d*, Longitudinal section of a 12.5-day-p.c. forelimb. Bar, 200 μm. *e*, Sagittal section of a 12.5-day-p.c. hindlimb extremity; the footplate points to the right. L, left limb bud; R, right limb bud; AER, apical ectodermal ridge; Ec, ectoderm; Pr, proximal; Di, distal; PB, precartilaginous blastemas; BV, blood vessels.

METHODS. Murine RARα, mRARβ, mRARγ (ref. 21) and CRABP (ref. 26) full-length cDNAs subcloned into plasmid pSG5 (ref. 34) in an antisense orientation were used as templates in a T7 polymerase *in vitro* transcription reaction. α-^{35}S-labelled CTP (Amersham) was added to the reaction to yield antisense RNA probes of specific activity ~5.10^{8} c.p.m. μg^{-1}. Probe average length was reduced to ~100 nucleotides by limited alkaline hydrolysis. Collection, paraformaldehyde fixation, paraffin embedding and sectioning of mouse embryos were carried out as described in ref. 35. The *in situ* hybridization protocol was previously described[35], except that the prehybridization step was omitted. Contiguous sections (5-μm thick) were hybridized respectively to each of the four probes, in a sequentially repeated manner so that 50-μm regularly spaced section planes were analysed. Emulsion autoradiography exposures were for 14 days for mRARs probes, and for 7 days for the CRABP probe. Specificity controls included hybridization of parallel sections to α-^{35}S-labelled dATP tailed oligonucleotide probes corresponding to regions of least homology across the mRARs. These probes resulted in the same signal distribution as that obtained with riboprobes, but longer exposure times were required.

(Fig. 1*d, e*) and surrounding the limb axial blood vessels (Fig. 1*d*, BV), with very little CRABP expression in the distal mesenchyme where mRARγ transcripts were homogeneously distributed. At the same stage, mRARα transcripts were widely distributed (Fig. 1*e*), whereas mRARβ transcripts (Fig. 1*e*) were only expressed in a discrete proximal region of the hindlimb mesenchyme, distinct but adjacent to the zeugopod PB, and in several regions of loosely packed cells in the forefoot and hindfoot plates, similar to that shown in Fig. 1*e*.

By day 14.5 p.c., mRARγ transcripts were found exclusively in the epidermal and dermal layers of the fetal skin (Fig. 2*a, d*) and in the cartilage cells of every bone model (Fig. 2*a, b*), with maximal expression in their growing extremities (for example, that of humerus in Fig. 2*a*) and no significant expression in ossification centres. Nevertheless, mRARγ labelling remained more diffuse in the extremities of the fingers (Fig. 2*c*) where bones, muscles and skin had not yet differentiated (see legend to Fig. 2). By contrast, the mRARα gene was expressed in all tissues including muscle, skin and perichondrium, but at lower levels in cartilage (Fig. 2*a–d*). Murine RARβ transcripts were highly restricted to mesenchymal cells located in the interdigital regions (Fig. 2*b, c*). CRABP transcripts were selectively distributed at the periphery of cartilaginous bone models and in the dermis, but not in the epidermal layer, nor in muscles (Fig. 2*a–d*). It is interesting that CRABP transcripts were not detected in the precise regions of the digits where the genes encoding mRARβ and mRARγ were maximally expressed, although they were clearly seen in the surrounding mesenchyme (Fig. 2*b, c*).

The fact that the genes encoding the three RARs are differentially expressed at the time of cytodifferentiation in the murine

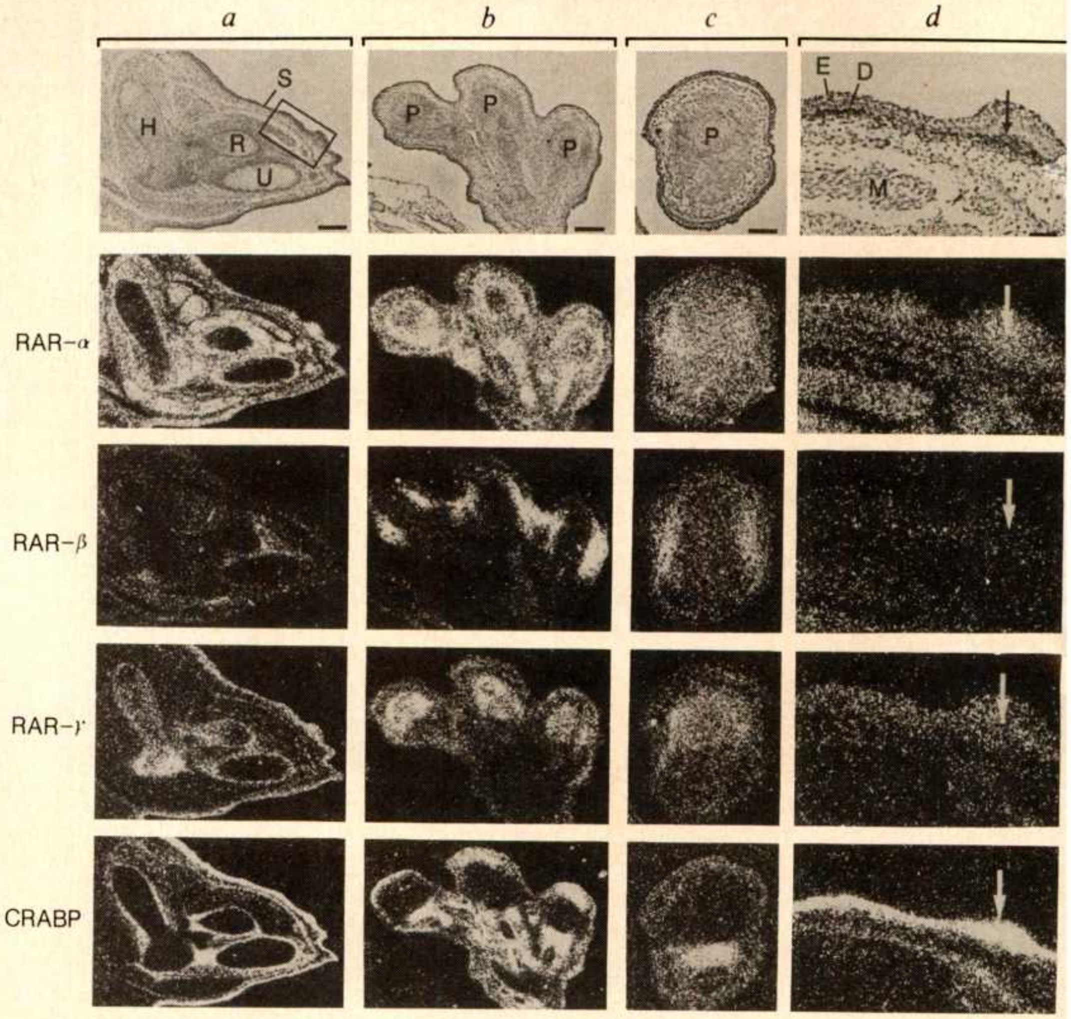

FIG. 2 Distribution of mRARs and CRABP transcripts in the limbs by gestational day 14.5 p.c. Top panels are bright-field views and lower panels show dark-field views of contiguous sections hybridized to mRARα, mRARβ, mRARγ and CRABP probes as indicated. *a*, Sagittal section of the elbow region, crossing the fetal humerus, radius and ulna. Note that at this stage of development the distal region of the humerus (H) and the proximal region of the radius (R) which are seen in this section contain both cartilaginous areas (lower part in the humerus, left part in the radius) and an ossification centre (upper part in the humerus, right part in the radius), whereas the section crosses the ulna essentially in an ossification centre. Bar, 200 μm. *b*, Section across the extremity of the hindlimb, crossing three digits. Bar, 160 μm. *c*, Transverse section of a forelimb finger extremity, just distal to the interdigital cleft. The distal regions of the fingers are still poorly differentiated; this is particularly clear in the case of the skin where the epidermis and dermis are not yet differentiated (compare with upper panel of *d*) and for the central condensation where chondrogenesis is not yet complete. The mRARβ signal is restricted to the mesenchyme facing the adjacent digits, whereas the mRARγ signal is more evenly distributed, although enhanced in the central condensation. Bar, 100 μm. *d*, Higher magnification of the region of the forelimb boxed in *a*. The arrows point to the basal lamina separating the dermis (D) and the epidermis (E); mRARα labelling appears ubiquitous (including muscles (M), whereas no significant mRARβ labelling is seen, mRARγ appears to be expressed both in dermis and epidermis, and CRABP is expressed in the dermis to such a great extent that the autoradiography grain is visible on the bright-field view (top panel), but not in the epidermis or in muscles. Bar, 75 μm. H, humerus; R, radius; U, ulna; S, skin; P, phalangeal bone anlagen; E, epidermis; D, dermis; M, muscle.

limb, strongly supports the idea that each RAR performs specific functions[21,22]. The specific localization of mRARγ transcripts in the cartilaginous cell lineage and in the differentiating skin, which extends throughout the embryo[27], indicates that mRARγ could mediate the effects of retinoic acid on chondrogenesis[11,28,29] and on skin differentiation[30]. The expression of the gene encoding mRARβ could be associated with programmed cell death[31], because it is highly restricted to the mesenchyme of the interdigital regions at the time of digit separation, and to their possible precursor areas in the differentiating footplates. CRABP transcripts are generally excluded from the areas expressing the mRARβ and mRARγ genes (although they are present in the surrounding regions) and to a large extent from those areas expressing the gene encoding mRARα. Thus, it seems possible that CRABP is not directly involved in the transduction of the retinoic acid signal by RARs. Whether it has a role in the control of free retinoic acid levels as previously suggested by its gradient distribution in the chick limb bud[16] is unknown. It is noteworthy that CRABP transcripts are preferentially localized in the skin dermal layer, whereas the genes encoding mRARα and mRARγ are expressed in both dermis and epidermis, because skin differentiation could be programmed by progressive migration of keratinocytes away from the dermal vascular source of retinoids[32,33]. □

THE *p53* gene has been a constant source of fascination since its discovery nearly a decade ago[1,2]. Originally considered to be an oncogene, several convergent lines of research have indicated that the wild-type gene product actually functions as a tumour suppressor gene[3-9]. For example, expression of the neoplastic phenotype is inhibited, rather than promoted, when rat cells are transfected with the murine wild-type *p53* gene together with mutant *p53* genes and/or other oncogenes[3,4]. Moreover, in human tumours, the short arm of chromosome 17 is often deleted (reviewed in ref. 10). In colorectal cancers, the smallest common region of deletion is centred at 17p13.1 (ref. 9); this region harbours the *p53* gene, and in two tumours examined in detail, the remaining (non-deleted) *p53* alleles were found to contain mutations[9]. This result was provocative because allelic deletion coupled with mutation of the remaining allele is a theoretical hallmark of tumour-suppressor genes[11]. In the present report, we have attempted to determine the generality of this observation, that is, whether tumours with allelic deletions of chromosome 17p contain mutant *p53* genes in the allele that is retained. Our results suggest that (1) most tumours with such allelic deletions contain *p53* point mutations resulting in amino-acid substitutions, (2) such mutations are not confined to tumours with allelic deletion, but also occur in at least some tumours that have retained both parental 17p alleles, and (3) *p53* gene mutations are clustered in four 'hot-spots' which exactly coincide with the four most highly conserved regions of the gene. These results suggest that *p53* mutations play a role in the development of many common human malignancies.

To search for mutations, two approaches were used, both based on the polymerase chain reaction[12] (PCR) (Fig. 1). For tumour cell lines and for xenografts passaged in athymic nude mice, complementary DNA was generated from messenger RNA using oligo(dT) as a primer. A 1,300 base-pair (bp) fragment including the entire *p53* coding region was generated from the cDNA using PCR, and this fragment was cloned and sequenced in its entirety. For primary tumours, sufficient RNA was often not available for the first approach, and PCR was used to generate a 2.9-kilobase (kb) fragment from tumour DNA. This was the longest fragment that we could reproducibly amplify from the *p53* locus, and included all of the exons found to contain mutations through the first approach.

Using these approaches, we analysed *p53* sequences of tumours derived from the breast, lung, brain, colon or mesenchyme. Tumours of these types have been previously shown to exhibit frequent deletions of chromosome 17p when studied by restriction-fragment length polymorphism (RFLP) methods[10]. To test for allelic deletions, tumour DNA samples were digested with *Hin*fI and, following Southern transfer, hybridized sequentially to two probes (p144D6 (ref. 13) and pYNZ22.1 (ref. 14)) detecting variable-number tandem-repeat ('VNTR' or 'minisatellite') sequences. DNA samples from normal tissues exhibited two alleles with at least one of these probes in 29 of 31 different individuals tested. Because of this high degree of polymorphism, allelic loss could be assessed with greater than 95% certainty in cell lines and xenografts, even when corresponding normal tissue was not available for comparison.

Nineteen tumours with allelic deletions of chromosome 17p were selected for sequence analysis. Thirteen of the tumours were found to contain a single missense mutation, two tumours each contained two missense mutations, one tumour contained a frame-shift mutation at codon 293, and no mutation was detected in three tumours (Table 1). The PCR reaction is known to be associated with a relatively high rate of base misincorporation[12], and we confirmed this observation by noting several sequence variants (13 out of 34,000 bp sequenced) in individual clones that were not reproducibly present in other PCR reactions from the same tumour sample. All of the mutations listed in Table 1 were confirmed by performing a second PCR reaction and re-sequencing the products *en masse* as described in the legend to Fig. 2.

Two observations indicated that the nucleotide substitutions described in Table 1 represented somatic mutations. First, none of these presumptive mutations have been observed in the sequences of human *p53* genes derived from normal cells, SV40-transformed fibroblasts, or lymphoblastoid cell lines (ref. 15, and references therein). Second, in six cases (tumours 2, 3, 9, 12, 13, 16), normal tissue from the patients whose tumours are described in Table 1 were available for study. To test for the presence of the presumptive mutations in the germline of these patients, a strategy was devised that used both PCR and cloning. Although direct sequencing of PCR products has been shown to be possible by several methods, we found that none of the published methods could be reproducibly applied to all parts of the *p53* coding region. To circumvent this difficulty, we cloned the PCR products into a phagemid vector and used the DNA pooled from 10^3 to 10^4 independent phage clones as a template for DNA sequencing (see legend to Fig. 2). This procedure resulted in sequence data quality as high as that produced using individual plasmid DNA clones as templates, and was used to demonstrate that in each of the six cases noted above, the mutations in the tumour DNA were not present in the germline of the patient (examples in Fig. 2).

The data described above indicated that most tumours with one *17p* allele contained a mutation of the *p53* gene in the remaining allele. To begin to assess the status of tumours that had not lost a 17p allele, we examined cDNA clones from three such tumours. In each case, two cDNA clones derived from PCR products, generated as described in the legend to Fig. 1, were sequenced. In one case (tumour 11), both clones contained a single point mutation at codon 134 (Table 1). In the second case (tumour 16), one clone contained a point mutation at codon 281 and one clone was wild-type. In the third case (tumour 17), both clones were wild-type. To assess the relative expression levels of the mutant alleles, the sequencing strategy described

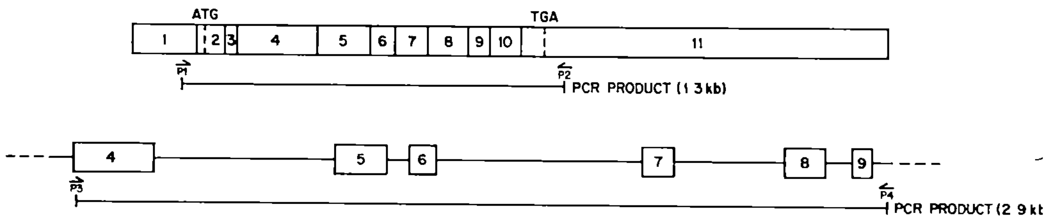

FIG 1 Strategies for amplification of *p53* gene sequences Messenger RNA was used to generate a cDNA template for a polymerase chain reaction (PCR) using primers P1 and P2 (top) The PCR product was 1 3 kb long and included the entire coding region Alternatively, total genomic DNA was used in a PCR reaction using primers P3 and P4 The PCR product was 2 9 kb long and included exons 4–9 (bottom) The numbered boxes indicate exons and the vertical dotted lines indicate the start (ATG) and stop (TGA) codons respectively

METHODS RNA was purified using guanidium isothiocyanate and mRNA selected by binding to Messenger Affinity Paper (Amersham) Complementary DNA was synthesized from 500–750 ng of mRNA using oligo(dT) as a primer The oligo(dT) primer was removed by isopropanol precipitation, 10 μg of transfer RNA and sodium perchlorate (to a final aqueous concentration of 0 5 M) were added to the reaction, and this was followed by addition of 1/2 volume of isopropanol[27] The cDNA was pelleted by centrifugation for 15 min at room temperature and used in a 50-μl PCR reaction consisting of 35 cycles of 93 °C (1 min), 58 °C (1 min), and 70 °C (2 min) Genomic DN (2 μg) was used in a 200-μl PCR reaction consisting of 30 cycles at 95 ° (1 min), 58 °C (1 min), and 70 °C (4 min) PCR reactions contained magnesiu chloride at a final concentration of 2 mM The primers used were P 5′-GGAATTCCACGACGGTGACACG-3′, P2, 5′-GGAATTCAAAATGGCAGGGG AGGG-3′, P3, 5′-GTAGGAATTCGTCCCAAGCAATGGATGAT-3′, P4, 5′-CATCGA ATTCTGGAAACTTTCCACTTGAT-3′ All primers had extraneous nucleotide comprising *Eco*RI sites at their 5′ ends to facilitate cloning The PCR product were digested with *Eco*RI, fractionated by electrophoresis, and followin purification from agarose, ligated to *Eco*RI digested Bluescript vector (Strategene) Individual clones were sequenced with primers derived fro the p53 coding and intron sequences[15] using T7 polymerase

in the legend to Fig 2 was used using cDNA from tumour mRNA as a template In tumour 11, only the mutant allele was expressed (data not shown), in tumour 16, the mutant and wild-type alleles were expressed at approximately equal levels (Fig 2, panel 4)

The fact that three (tumours 5, 8 and 10) of the 19 tumours with single chromosome 17p alleles did not contain *p53* gene mutations has potentially important practical and conceptual implications At least three explanations could account for this result First, it is possible that mutations existed in these three tumours but were outside the region sequenced Such mutations could affect the transcription of *p53* mRNA, its stability or translational capacity Experiments to test this possibility are in progress, but it is notable that although tumour 5 expressed *p53* mRNA, no p53 protein could be detected on western blots (S E Kern and J M N , unpublished data) Alternatively, it is possible that a second tumour suppressor gene on chromosome 17p exists and was the target of allelic deletion in some tumours Finally, the possibility that some allelic deletions represent 'nonselected losses', coincidently occurring with other independent mutations elsewhere in the genome, cannot be excluded

Neurofibrosarcomas are tumours that predominantly occur in patients with neurofibromatosis type I This syndrome can be inherited in an autosomal dominant fashion, and the gene responsible for it (*NF*) has been mapped to chromosome 17q near the centromere[16] Interestingly, chromosome 17 sequences are lost from neurofibrosarcomas from these patients, but the region of deletion sometimes includes the short arm and does not include the region of 17q harbouring the *NF* gene (T G and B Seizinger, unpublished data) The result shown in Table 1 (tumour 12) suggests that a target of allelic deletion, in at least one neurofibrosarcoma, was *p53*

Altogether, 20 point mutations (19 missense, 1 frameshift) were identified in the present study These are mapped in Fig 4, together with the two human *p53* gene missense mutations previously described[9] Several features are notable Although the sample size is limited, the mutations tended to be clustered in four hotspots which accounted for 86% of the 21 missense mutations (five mutations in region A, codons 132–143, five mutations in region B, codons 174–179, three mutations in region C, codons 236–248, five mutations in region D, codons 272–281) There have been two missense mutations identified in murine tumour cells, both in the carcinogen-induced fibrosarcoma cell line Meth A one allele contained a mutation in region A, and the other contained one mutation in region C and one mutation in region D[17,18] Interestingly, the four hotspots for *in vivo* mutation coincided exactly with the four most highly conserved

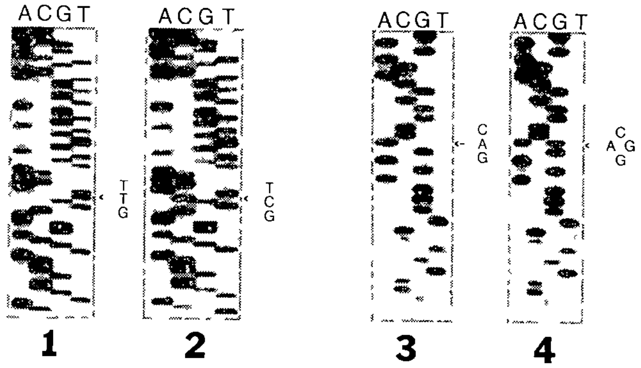

FIG 2 Examples of sequencing reactions demonstrating *p53* gene mutations The templates used for the sequencing reactions shown in panels 1–4 consisted of pools of greater than 10^3 clones generated from PCR products Tumour 13 genomic DNA contained a mutation at codon 239 (antisense GCT, panel 2), instead of the wild-type sequence (GTT) found in the genomic DNA from normal lymphocytes from the same patient (panel 1) Panel 4 shows a sequencing reaction of pooled cDNA clones from tumour 16 showing that both wild-type codon 281 (GAC) and mutant codon 281 (GGC) were both expressed Only the wild-type sequence (GAC) was found in pooled genomic DNA clones from normal lymphocytes of this patient (panel 3)

METHODS PCR reactions were carried out as described in the legend to Fig 1, and the reaction products digested with *Eco*RI The entire reaction was ligated to 0 25 μg of λ ZAP phage vector arms (Stratagene) and packaged using 1/4 of a GIGA-Pack extract (Stratagene) *Escherichia coli* BB4 cells were then infected, and 10^3–10^4 phage clones plated on a 7-cm Petri dish The λ ZAP vector contains the sequences for a phagemid into which the PCR inserts were cloned, and single-stranded DNA phage can be rescued from the λ phage clones using a helper phage[28] An overnight culture of XL-1 Blue cells (Stratagene) was grown in 0 4% maltose and resuspended in 1 5 volumes of 10 mM magnesium sulphate Phages were eluted from the 7-cm dish in 5 ml phage-dilution buffer (100 mM sodium chloride, 10 mM magnesium sulphate, 20 mM Tris, pH 7 5, 0 02% gelatin) for 2 h at room temperature with gentle agitation Fifty microlitres of eluate was used to infect 200 μl of XL-1 Blue cells (Stratagene) in the presence of 1 μl helper phage R408 (10^{11} P F U per ml) After 15 min at 37°, 5 ml of 2 × YT broth was added and the culture shaken for 3 h at 37 °C, then heated to 70 °C for 20 min Cell debris was pelleted at 3,000*g* for 5 min, and 10 μl supernatant, containing single-stranded DNA phage, was used to infect 200 μl of XL-1 Blue cells, prepared as described above After 15 min at 37 °C, 100 μl of the mixture (containing over 10^4 clones determined by titration on XL-1 Blue cells) was inoculated into 50 ml L-broth and shaken overnight at 37 °C Double-stranded DNA was isolated by alkaline lysis and sequenced as described in the legend to Fig 1 The primer used for sequencing in panels 1 and 2 was 5′-GAGGCAAGCAGAGGCTGG-3′ The primer used for sequencing in panels 3 and 4 was 5′-TGGTAATCTACTGGGACG-3′

TABLE 1 *p53* gene mutations in human tumours

Tumour	Tumour name	Tumour type*	Tumour cells tested†	Number of 17p alleles‡	Codon	Mutation

* The brain tumours were glioblastoma multiforme, the colon and breast tumours were adenocarcinomas, the NFS tumour was a neurofibrosarcoma developing in a patient with type-I neurofibromatosis, H231 was a small cell carcinoma of the lung, and the other two lung tumours were non-small-cell carcinomas

† B, Tumour biopsy, C, cell line passaged *in vitro*, X, xenograft derived from biopsy, passaged in athymic nude mice Whenever two sources of tumour cells are listed, both contained the indicated mutation

‡ The number of alleles was determined by RFLP analysis, as described in the text

regions of the *p53* gene, previously identified by Soussi *et al*[19] Of the 41 amino acids contained within regions A–D, 93% are identical in the wild-type *p53* genes of amphibian, avian and mammalian species, compared to a conservation of only 51–57% over the entire *p53* coding sequence The clustering of mutations and evolutionary conservation of regions A–D suggest that they play a particularly important role in mediating the normal function of the *p53* gene product

Previous cytogenetic and RFLP studies have shown that allelic deletions of chromosome 17p occur in at least 60% of tumours of the colon, breast, lung, ovaries, cervix, adrenal cortex, bone and bladder, and in at least 30% of brain tumours[10,20-23] These tumour types account for most of the neoplasms occurring in humans Our data suggest that the great majority of tumours with 17p allelic deletions contain mutant *p53* genes, and similar mutations occur in at least some tumours without 17p allelic deletions

These data lead to the following hypothesis Mutations in the *p53* gene occur during the process of tumorigenesis, and through a dominant negative effect[3-5,9,24], cause tumour progression The dominant negative effect may be mediated by binding of the mutant p53 product to the wild-type product, creating an inactive oligomeric complex[18,25] Because wild-type products remain in the cell, however, a further loss of growth control can be exerted when the wild-type allele is deleted, leaving the cell with only a mutant allele The first example of an intermediate step in this scheme is provided by tumour 16, which had not lost a chromosome 17p allele, but had developed a *p53* gene mutation and expressed both the wild-type and mutant alleles (Table 1 and Fig 2) We imagine that tumour 16, had it not been surgically removed, would have eventually lost the wild-type *p53* gene through allelic deletion Indeed, it has been shown that the loss of a chromosome 17p allele is significantly associated with tumour progression in the human host[26] Although this model requires much further study before it can be verified, it is now supported by several lines of research, including the demonstration of mutant *p53* genes in most tumours with 17p allelic losses ☐

THE *ZFY* gene in the sex-determining region of the human Y chromosome encodes a protein with 13 zinc fingers, and may determine whether an embryo develops as a male or female[1]. *ZFX*, a related gene on the human X chromosome, may also function in sex determination; it encodes a protein with a very similar zinc-finger domain and escapes X inactivation[1,2]. *ZFY* and *ZFX* diverged from a common ancestral gene before the radiation of placental mammals, and retain a similar genomic organization[2]. Analysis of complementary DNAs from the mouse Y-chromosomal homologues of *ZFY* indicates that these genes encode probable transcription activators[3,4] Here, we report that *ZFX* encodes a protein composed of a highly acidic amino-terminal domain, a basic putative nuclear-localization signal, and a carboxy-terminal zinc-finger domain. This combination of features, also found in the *ZFY* gene product, is typical of transcription activators. Alternative splicing generates *ZFX* transcripts encoding isoforms of 575 and 804 amino acids. These ZFX protein isoforms differ in the length of their acidic domains and may be functionally distinct.

ZFX is transcribed in all human cells analysed[2] We cloned *ZFX* cDNAs from a male lymphoblastoid cell line Analysis by restriction mapping and hybridization with genomic probes revealed three distinct types of cDNAs Whereas two types were represented by a single clone each (cDNAs 1 and 3), a third type was represented by three clones (cDNAs 2, 4 and 5)

We determined the nucleotide sequence of one cDNA of each type (Fig 1) Comparison of cDNAs 1, 2, and 3 showed that alternative splicing and polyadenylation had produced structurally distinct 5′ untranslated, coding, and 3′ untranslated regions (Fig 2*a*) Differential splicing involved an invariant donor site (nucleotide −378) and alternative acceptor sites (at nucleotides +647, −28 and −377, in cDNAs 1, 2 and 3, respectively) Each cDNA contains a single long open reading frame (ORF), and in each case the first ATG occurs in a sequence context favourable for initiation of translation[5] Complementary DNAs 2 and 3, with identical ORFs, encode a protein of 804 amino acids (ZFX^{804}), whereas cDNA 1 encodes an isoform of 575 amino acids (ZFX^{575}) (Alternatively, with cDNA 1, translation initiation at a second ATG, whose context is highly favourable, would result in production of an isoform of 573 amino acids) *In vitro* transcription and translation of cDNAs 3 and 1 yielded the predicted full-length and truncated proteins, respectively (data not shown) Both ZFX protein isoforms contain three domains—an N-terminal acidic portion (25% aspartic and glutamic acid), a small basic domain, and a C-terminal run of 13 zinc fingers, each with two cysteines and two histidines (Cys-Cys/His-His zinc fingers) The isoforms differ in that the acidic domain of ZFX^{575} is half that of ZFX^{804}

FIG 1 Composite nucleotide sequence of *ZFX* cDNAs 1, 2 and 3 (Fig 2*a*) and predicted amino-acid sequences Numbering of nucleotides and amino acids is with reference to the first in-frame ATG codon in cDNAs 2 and 3 Known splice sites are indicated by upward arrows Alternative starts of poly(A) tails are indicated by downward arrows Complementary DNA 1 begins at nucleotide −527, uses a splice donor site at −378 and an acceptor site at +647, a tail of 20 adenosines follows nucleotide 2,585 Complementary DNA 2 starts at nucleotide −426, uses the same donor, but a different acceptor at −28, a tail of 46 adenosine residues follows nucleotide 5,450 Complementary DNA 3 starts at nucleotide −426, uses the same donor, but yet another different acceptor at −377, a tail of 26 adenosines follows nucleotide 3,298 Complementary DNAs 2 and 3 contain the same ORF with the first in-frame ATG codon at nucleotide 1, the predicted protein of 804 amino acids is composed of an acidic N-terminal domain, a small basic domain (residues 391–406, boxed), and 13 zinc fingers (cysteines of the Cys-X-X-Cys repeats are circled) Complementary DNA 1 has a shorter ORF with the first in-frame ATG codon at nucleotide +688, encoding a protein of 575 residues The 3′ UTR of cDNA 2 contains an *Alu* sequence[16] (nucleotides +3,959 to +4,250, boxed) An AATAAA polyadenylation signal[17] occurs 20 nucleotides 5′ of the poly(A) tail of cDNA 2 Similar sequences are present 5′ of the poly(A) tails in cDNAs 1 and 3

METHODS Complementary DNA libraries were prepared[3] using poly(A)$^+$ RNA prepared[2] from human male lymphoblastoid cell line WHT1659 Five million recombinant phages from unamplified libraries were screened using plasmids pDP1007, pDP1041 and pDP1006 (*ZFY* genomic fragments which cross-hybridize to *ZFX*)[1,2] as probes Complementary DNA inserts of seven phages were subcloned into Bluescript vectors (Stratagene) The full DNA sequences of three inserts and partial sequences of the other four inserts were determined[2] As judged by comparison with genomic sequences, five cDNAs originated from *ZFX* and two from *ZFY*

Comparison of *ZFX* cDNAs with the genomic locus by restriction mapping and oligonucleotide hybridization gave an overview of the intron-exon organization (Fig 2*a*) The C-terminal zinc-finger domain and 3′ untranslated region (UTR) are encoded by a single exon, whereas the N-terminal acidic domain is encoded by a minimum of four exons for ZFX^{575} (cDNA 1) and a minimum of six exons for ZFX^{804} (cDNAs 2 and 3) The cDNAs span 67 kilobases (kb) in the genome

Of the three types of cDNAs, type 2, encoding ZFX^{804}, seems to be most representative of the 6 3- and 8-kb transcripts observed on northern blots[2] First, the coding exon defined by oligonucleotides ‘150’ and ‘637’ is present in cDNAs 2 and 3 but not in cDNA 1 (Fig 2*a*) Northern analysis using the corresponding genomic DNA fragment revealed that this exon is present in the 6 3- and 8-kb transcripts (not shown) Second, northern analysis indicated that the polyadenylation site used in cDNA 2 corresponds, at least roughly, to the 3′ end of the main *ZFX* transcripts (data not shown) Clone 2, which is 5 6 kb long, could represent a 6 3- or 8-kb transcript that is incomplete at the 5′ end

Transcripts corresponding to cDNA 1, encoding ZFX^{575}, have not been detected by northern analysis Using polymerase chain reaction (PCR) amplification, however, we confirmed the differential splicing predicted from cDNA analysis and crucial to the generation of ZFX protein isoforms (Fig 2*b*) We designed splice-specific 5′ primers spanning splices of the invariant donor site at nucleotide −378 to alternative acceptor sites at nucleotides +647, −28 and −377, as in cDNAs 1, 2 and 3, respectively The

3′ primer was common to all three cDNAs Bulk cDNA generated by reverse transcription of male or female lymphoblastoid RNA was used as template Fragments predicted from the sequences of cDNA clones 1, 2 and 3 were amplified (Fig 2*b*), confirming the differential splicing shown in Fig 2*a* Some unanticipated fragments were simultaneously amplified (Fig 2*b*)

The ZFX^{804} protein has a primary sequence strikingly similar to those encoded by the mouse *ZFY* homologues (*Zfy*-1 and *Zfy*-2)[3,4], with which it shares virtually identical N and C termini ZFX^{804} and ZFX^{575} proteins are also similar to the human ZFY protein (ref 1, and P B -R and A S -G, unpublished results) Each of these proteins is composed of an acidic domain, a small basic domain, and 13 Cys-Cys/His-His zinc fingers This combination of features is reminiscent of those of eukaryotic transcription activators[6] By analogy, we assume that ZFX and ZFY proteins activate transcription in a sequence-specific fashion When fused to the DNA-binding domain of GAL4, the acidic domains of mouse Zfx and Zfy-2 do activate transcription in yeast[7]

Are the various ZFX and ZFY proteins functionally distinct? All share a small basic domain, which could localize the proteins to the nucleus[8,9] Cys-Cys/His-His zinc-finger domains[10,11] bind to nucleic acids in a sequence-specific fashion The zinc-finger domains of ZFX^{804} and ZFX^{575} are identical and differ from the zinc-finger domain of human ZFY at only 10 of 393 amino acids[2] Thus ZFX^{804}, ZFX^{575} and ZFY proteins could all recognize the same nucleic-acid target sequences, and thereby perhaps regulate transcription of the same genes

The N-terminal portions of the ZFX and ZFY proteins are highly acidic Acidic domains mediate activation in several eukaryotic transcription factors[12-15] The potency of such activating domains may depend more on the number and density of acidic residues than on particular primary sequences[5] In ZFX^{804} and mouse Zfx, Zfy-1 and Zfy-2, the acidic domains are of similar size, each with ~25% of residues acidic By contrast, ZFX^{575} contains an abbreviated acidic domain ZFX^{804} and ZFX^{575} might be expected to have quantitatively different activating potencies Furthermore, acidic domains of transcription factors are believed to interact with other proteins in transcription complexes Truncation of the acidic domain in ZFX^{575} could alter its interactions with other factors, resulting in qualitatively different regulatory properties (Internal ATG codons in human *ZFY* and mouse *Zfx*, *Zfy-1* and *Zfy-2* could allow production of similarly truncated isoforms)

We compared the human *ZFX* cDNA sequence with that of a murine *Zfx* cDNA (ref 7, Fig 3) The coding regions of *ZFX* and *Zfx* show a high degree of similarity It is of interest that the 3′ UTR is also conserved Except for an *Alu* insertion in the human sequence, the entire human 3′ UTR of 3 kb shows over 80% nucleotide identity with the murine 3′ UTR

Given the similarity in the primary structure of the ZFX protein and its Y chromosome-encoded homologues, it is conceivable that the products of the *ZFX* and *ZFY* genes are

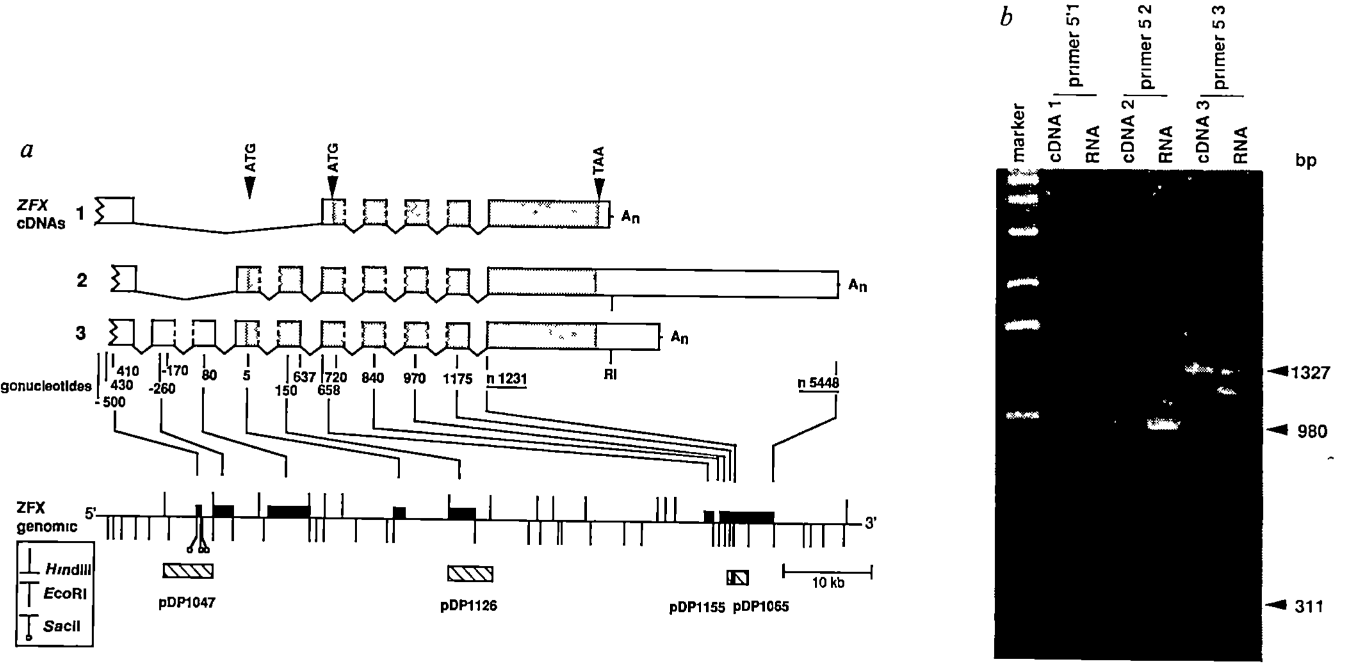

FIG 2 Analysis of alternative ZFX transcripts *a*, Organization of cDNAs and genomic locus Top boxes indicate the minimum number of exons and, with the exception of the 3′-most exon, are not to scale, coding regions are shaded Several splice sites (solid vertical lines of boxes) were defined by DNA sequence comparison among cDNA clones 1, 2 and 3 or by comparison with genomic sequences Additional splices (dashed vertical lines of boxes) are not precisely defined but inferred from comparison of cDNA and genomic restriction maps Boxes bounded by dashed lines may contain more than one exon each Genomic DNA fragments[2] hybridizing (5–10 °C below calculated melting temperature) with *ZFX* oligonucleotides (numbers denote the 11th nucleotide in 20-mer oligonucleotides) are shown by black segments, each contains one or more exons *b*, PCR analysis of differential splicing Three different 5′ primers (20mers) spanning splices unique to cDNAs 1, 2 or 3 have in common the invariant donor site at nucleotide −378, but each includes a unique acceptor (−389 to −378/+647 to +654 (primer 5′1), −383 to −378/−28 to −15 (primer 5′2), −381 to −362 (primer 5′3)) An invariant 3′ primer (+923 to +946) was used Using cDNA clones 1, 2 and 3 as templates, the predicted products were amplified (cDNA 1, 311 base pairs (bp), cDNA 2, 980 bp, cDNA 3, 1,327 bp) Using 'RNA' (bulk cDNA prepared from male lymphoblastoid WHT1659 RNA by reverse transcription) as template, products of the same lengths were obtained In addition, with bulk cDNA, primer 5′2 amplified a 1 1-kb fragment (which may incorporate additional coding exon(s) not detected by cDNA cloning), whereas primer 5′3 amplified a barely detectable 1 4-kb fragment (possibly incorporating additional coding or 5′ UTR exon(s)) and a 1 2-kb fragment (which may lack coding or 5′ UTR exon(s) present in cDNA 3) Controls not shown (1) The 5′ primers are splice specific, yielding products only with the corresponding cDNAs, (2) amplification of cell line RNA, without reverse transcriptase, yielded no products, (3) by using bulk cDNA from female lymphoblastoid cell line WHT1628 as template, products of the same lengths were obtained, and (4) hybridization of Southern blots of these gels verified that the ethidium bromide-detected products originate from *ZFX*

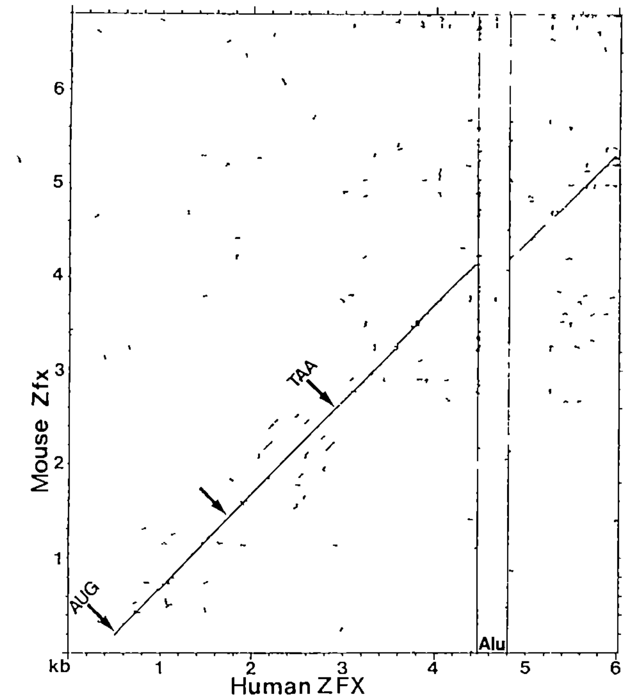
METHODS Poly(A)$^+$ RNA (200 ng) was reverse-transcribed using Moloney reverse transcriptase (Bethesda Research) Forty cycles of amplification were performed using *Taq* polymerase and a DNA Thermo Cycler (Cetus) Each PCR reaction (10%) was separated on an agarose gel and stained with ethidium bromide The marker lane contains a '1-kb ladder' (Bethesda Research)



Homology between human ZFX and mouse Zfx

	% Identity		No of gaps
	DNA	protein	
Coding region			
N-terminal domain	90	92	2
Zinc finger domain	93	99 5	0
3 untranslated region			
5 of *Alu* insertion	85	-	19
3 of *Alu* insertion	81	-	22

FIG 3 Nucleotide and corresponding amino-acid similarity between human *ZFX* (Fig 1) and murine *Zfx* (ref 7) Striking similarity is found not only in the coding region, but also across the entire 3′ UTR (except for an *Alu* insertion, indicated by vertical lines, in the human), and ~20 nucleotides 5′ of the ATG codon Arrows indicate the start codon in *ZFX* cDNAs 2 and 3, the splice site preceding the zinc-finger exon, and the TAA stop codon Numbering (in kb) is with reference to the 5′ ends of the cDNAs The analysis[18] employed a 'window' of 21 and a 'stringency' of 14

functionally interchangeable But the occurrence of isoforms—at least of ZFX—indicates that *ZFX* and *ZFY* could produce transcription factors with qualitatively or quantitatively distinct functions The 3′ UTRs of *ZFX* transcripts are longer and more highly conserved than those found in *Zfy* transcripts[3 4], and could provide a basis for differential post-transcriptional regulation Detailed studies of *ZFX* and *ZFY* transcripts during development should further elucidate their postulated roles in sex determination ☐

THE cascade of biochemical events triggered by growth factors and their receptors is central to understanding normal cell-growth regulation and its subversion in cancer Ras proteins ($p21^{ras}$) have been implicated in signal transduction pathways used by several growth factors, including platelet-derived growth factor (PDGF)[1]. These guanine nucleotide-binding Ras proteins specifically interact with a cellular GTPase-activating protein (GAP)[2] Here we report that in intact quiescent fibroblasts, both AA and BB homodimers of PDGF rapidly induce tyrosine phosphorylation of GAP under conditions in which insulin and basic fibroblast growth factor (bFGF) are ineffective. Although GAP is located predominantly in the cytosol, most tyrosine-phosphorylated GAP is associated with the cell membrane, the site of $p21^{ras}$ biological activity[3,4] These results provide a direct biochemical link between activated PDGF-receptor tyrosine kinases and the $p21^{ras}$-GAP mitogenic signalling system

In human malignancies, *ras* genes are commonly activated as oncogenes and their p21 products are potently mitogenic when microinjected into quiescent fibroblasts[5,6] Yet the function of $p21^{ras}$ proteins in normal mitogenic signal transduction remains unknown It is well established that the GTP-bound forms of $p21^{ras}$ proteins are active and that the GDP-bound forms are inactive[7-9] The GAP protein of relative molecular mass 125,000 ($M_r \sim 125$K) catalyses the conversion of p21-GTP to p21-GDP so that the rate of this recycling is more than 100-fold faster than that intrinsic for p21 (ref 2) GAP has no effect on oncogenic p21 proteins, allowing them to remain in their active GTP-bound states

To investigate whether GAP serves as a substrate for activated growth factor-receptor kinases in intact cells, confluent NIH3T3 cells were rendered quiescent by incubating them overnight in serum-free medium Cells were exposed to saturating concentrations of PDGF BB homodimer for 5 min, after which cell lysates were subjected to immunoblot analysis with an antiphosphotyrosine antiserum (anti-P-Tyr) or anti-GAP peptide serum 638 (ref 10) PDGF BB homodimer induced the specific tyrosine phosphorylation of several proteins (Fig 1*a*) These included the α- and β-PDGF receptors each of M_r 185K (ref 11), a protein of M_r 145K that has been identified as phospholipase C_γ (ref 12), and several other proteins of M_r ranging from 50-125K Anti-GAP peptide serum 638, raised against GAP amino-acid residues 139-152 (ref 10), identified a single band corresponding to a protein of $M_r \sim 125$K, which was not observed in the presence of excess competing peptide (Fig 1*a*, lane 3)

When quiescent cells or cells treated with PDGF BB homodimer were first immunoprecipitated with either polyclonal or monoclonal anti-P-Tyr antibodies followed by immunoblotting with anti-GAP antiserum 638, GAP was detectable only in cells stimulated with PDGF BB homodimer (Fig 1*b*, lane 3) Similar results were observed using anti-GAP peptide serum 677 raised against GAP residues 968-981 (ref 10) Moreover, recovery of GAP by anti-P-Tyr antiserum was specifically inhibited by an excess of competing phosphotyrosine

(Fig 1*b*, lane 4), but not by phosphoserine or phosphothreonine (data not shown) Whereas these experiments were performed using saturating amounts of PDGF BB homodimer (100 ng ml^{-1}), increased levels of anti-P-Tyr-recoverable GAP were also observed using concentrations of PDGF BB that did not maximally induce DNA synthesis (data not shown) Taken together, these results imply that GAP is an early substrate of PDGF-receptor tyrosine kinases or is specifically co-immunoprecipitated with a tyrosine-phosphorylated substrate(s)

When cell lysates were first immunoprecipitated with an antiserum against recombinant GAP, a protein of M_r 125K was detected from either unstimulated (Fig 1*c*, lane 1) or PDGF BB homodimer-stimulated (Fig 1*c*, lane 2) cells Note that we reproducibly observed slightly better recovery of GAP from PDGF-stimulated cell lysates (Fig 1*c*, lane 2) When parallel immunoprecipitates were probed with anti-P-Tyr antiserum, only the 125K GAP band extracted from PDGF-stimulated cells was identified (Fig 1*c*, lane 4) These results confirm that GAP was tyrosine-phosphorylated in response to PDGF BB homodimer The GAP protein contains at least two consensus tyrosine-phosphorylation sites at residues 161 and 720 (ref 13) Recent studies have also indicated that GAP can serve as a substrate of tyrosine kinases *in vitro*[14,15] The precise location of the *in vivo* sites of GAP tyrosine phosphorylation remains to be determined

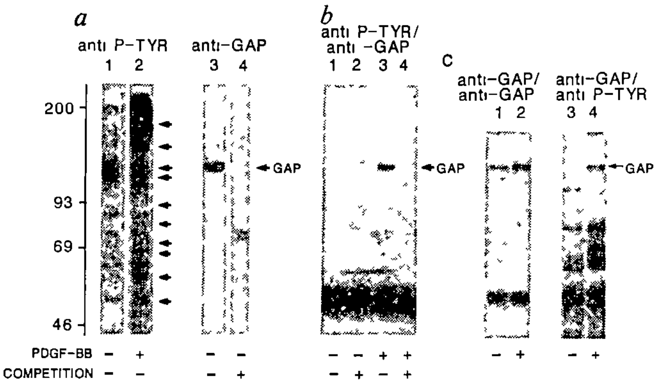

FIG 1 Tyrosine phosphorylation of GAP in PDGF BB homodimer-stimulated NIH3T3 cells *a*, Lanes 1 and 2, immunoblot of total cell lysates (100 μg) using anti-P-Tyr antiserum Cells were either quiescent or treated with PDGF BB homodimer for 5 min as indicated Lanes 3 and 4, immunoblot of cell lysates, using anti-GAP peptide serum 638 (ref 10) in the absence (lane 3) or presence (lane 4) of competing peptide *b*, Immunoblot of anti-P-Tyr antiserum-recovered proteins using anti-GAP antiserum Where noted, phosphotyrosine (5 mM) was added to the lysates before immunoprecipitation for competition Lanes 1 and 2, anti-P-Tyr antiserum immunoprecipitates from quiescent cells, lanes 3 and 4, anti-P-Tyr antiserum immunoprecipitates from PDGF BB homodimer-stimulated cells *c*, Anti-GAP serum 106 immunoprecipitates from quiescent (lanes 1 and 3) and PDGF BB homodimer-stimulated (lanes 2 and 4) cells were analysed by immunoblotting using either anti-GAP peptide serum 638 or anti-P-Tyr antiserum as indicated

METHODS After incubation in serum-free medium for 18 h, confluent NIH3T3 cells were either left untreated or stimulated with PDGF BB homodimer (Amgen) at 100 ng ml^{-1} for 5 min Cultures were rinsed twice in ice-cold PBS containing 1 mM Na_3VO_4, and lysed on ice in 0 5 ml P-Tyr lysis buffer (50 mM HEPES buffer pH 7 5, 1% Triton X-100, 50 mM NaCl, 50 mM NaF, 10 mM sodium pyrophosphate, 5 mM EDTA, 1 mM Na_3VO_4, 1 mM PMSF, in addition to 10 μg ml^{-1} aprotinin, leupeptin, and pepstatin A) Lysates were clarified by centrifugation at 12,000*g* at 4 °C for 10 min, and then immunoprecipitated with affinity-purified anti-P-Tyr antiserum[11,19], monoclonal anti-P-Tyr antibodies (PY 20, PY 69, ICN), or rabbit anti-GAP serum 106 raised against recombinant GAP (residues 128–1,044, J B G, unpublished results) for 2 h on ice Immune complexes were recovered using protein G-agarose (Gammabind G, Genex) Immunoprecipitates were washed five times in P-Tyr lysis buffer and then solubilized in SDS-PAGE sample buffer as previously described[19,29] Aliquots of the whole-cell lysates were removed before immunoprecipitation for immunoblot analysis Gel electrophoresis and immunoblotting were performed as previously described[11,29] Immunoreactive bands were visualized using ^{125}I-labelled protein A followed by autoradiography

We next monitored the recovery of GAP by anti-P-Tyr antiserum at different times after PDGF BB homodimer stimulation of quiescent cells PDGF BB homodimer induced rapid PDGF-receptor autophosphorylation, which increased over the first 10 min and then gradually decreased (Fig 2*a*) Similarly, increased recovery of GAP by anti-P-Tyr was observed within 1 min of PDGF addition, was maximal by $\sim$10 min, and persisted for at least 120 min (Fig 2*b*) In other experiments, we detected increased levels of anti-P-Tyr-recoverable GAP for up to 8 h after PDGF BB homodimer stimulation (data not shown)

GAP has previously been reported to be located in the cell cytosol[2] Because we found that GAP was rapidly tyrosine-phosphorylated in response to PDGF, we performed subcellular fractionation studies to determine the site of GAP tyrosine phosphorylation within the cell In quiescent fibroblasts, GAP was found predominantly in the cystolic fraction (Fig 3*a*, lane 2) But after stimulation of the cells with PDGF BB homodimer for 10 min, we observed a modest but reproducible increase in GAP associated with the particulate fraction concomitant with a slight decrease in the cytosolic component (Fig 3*a*, lanes 3 and 4) Anti-P-Tyr antiserum-recoverable GAP was observed only in the PDGF BB homodimer-stimulated cells and was most abundant in the particulate fraction (Fig 3*b*, lane 3) By comparing the relative signal intensities of anti-GAP immunoblots of anti-P-Tyr-recovered versus total GAP in the respective subcellular fractions, we estimated that at least 15–20% of the membrane-associated GAP protein was recovered by anti-P-Tyr antiserum immunoprecipitation and that <2% of cytosolic GAP could be recovered under the same conditions Because anti-P-Tyr immunoprecipitation is relatively inefficient (C J M , unpublished results), it is probable that a much greater fraction of the particulate (P-100)-localized GAP is tyrosine-phosphorylated in response to PDGF BB homodimer

The specificity of PDGF-induced GAP phosphorylation was analysed by comparing the responses of quiescent NIH3T3 cells to stimulation with saturating concentrations of several growth factors The addition of either PDGF AA homodimer, bFGF, or insulin-induced specific tyrosine phosphorylation of cellular proteins (Fig 4*a*) For example, bFGF caused tyrosine phosphorylation of a previously identified protein of M_r 90K (ref 16), and insulin induced tyrosine phosphorylation of proteins

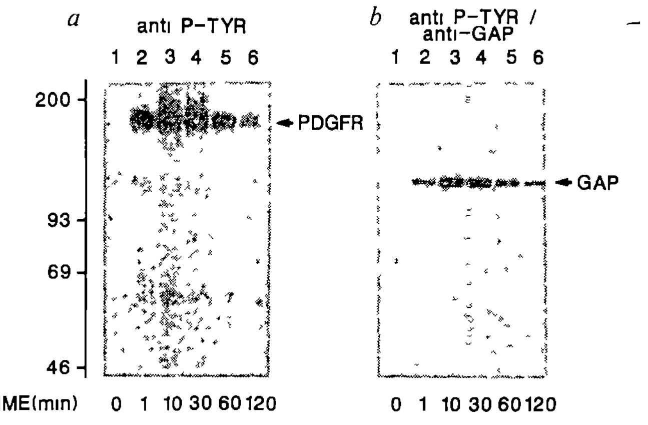

FIG 2 Time course of anti-P-Tyr antiserum recovery of GAP after PDGF BB homodimer stimulation *a*, Anti-P-Tyr antiserum immunoblot analysis of whole-cell lysates from unstimulated cells (lane 1) and cells stimulated by PDGF BB homodimer for the indicated time (lanes 2–6) Arrow denotes the autophosphorylation of PDGF receptors[11] *b*, Anti-GAP peptide serum 677 immunoblot analysis of anti-P-Tyr-antiserum immunoprecipitates from cells either unstimulated (lane 1) or stimulated with PDGF BB homodimer for the indicated times Arrow denotes the immunoreactive GAP protein recovered by anti-P-Tyr antiserum after PDGF BB homodimer stimulation Methods for immunoprecipitation and immunoblotting are described in the legend to Fig 1 Blots were exposed for 15 h using an intensifying screen

with M_rs of 175K and 95K, the latter corresponding to the β-subunit of the insulin receptor[17,18] Stimulation with both PDGF AA and BB homodimers led to increased anti-P-Tyr recovery of GAP (Fig 4*b*, lanes 2 and 3) In other studies using NIH3T3 cells overexpressing epidermal growth factor receptors[19], rapid anti-P-Tyr antiserum recovery of GAP has also been observed after stimulation with epidermal growth factor C J M , unpublished data) By contrast, neither insulin nor bFGF, under conditions in which bFGF was as mitogenically active as the PDGF homodimers, was able to induce detectable GAP tyrosine phosphorylation (Fig 4*b*, lanes 4 and 5) Thus there seem to be differences in the efficiency of GAP tyrosine phosphorylation in response to different growth factors

These studies demonstrate that GAP is tyrosine phosphorylated *in vivo* in response to specific growth factors Recent evidence indicates that PDGF and epidermal growth factor receptor kinases also rapidly induce tyrosine phosphorylation of other proteins, including the c-*raf* gene product[20], phosphatidylinositol kinase[21], and phospholipase C_γ (refs 22-24) The rapid and sustained time course of anti-P-Tyr antiserum recovery of GAP that we observed is very similar to that recently reported for PDGF-stimulated tyrosine phosphorylation of phospholipase C_γ (ref 24) Furthermore, as reported for phospholipase C_γ (ref 24), our preliminary experiments indicate that GAP co-immunoprecipitates with activated PDGF receptors (C J M , unpublished data) Taken together, these findings argue that GAP is an early direct substrate of certain growth factor receptors

Tyrosine phosphorylation is known to modulate the activity of several enzymes, including the *src* gene product[25,26] It is also well established that the $p21^{ras}$ molecule must be located in the membrane to be biologically active[1,3] Thus, our demonstration that GAP recovered by anti-P-Tyr antiserum is associated predominantly with the particulate fraction further indicates that tyrosine phosphorylation may alter the functional interaction of GAP and $p21^{ras}$ In one proposed model, GAP serves as an attenuator of $p21^{ras}$ function[2] If so, tyrosine phosphorylation of GAP could transiently remove its inhibition, allowing the $p21^{ras}$-GTP complex to effect mitogenic signalling through some unknown downstream components Another model proposes that GAP can act as a downstream effector as well as attenuator of $p21^{ras}$ function[2 27 28] Thus, tyrosine phosphorylation of GAP could modulate its effector role, perhaps by coupling the GAP-$p21^{ras}$ complex to other molecules By whatever mechanism tyrosine phosphorylation perturbs GAP-$p21^{ras}$ function, our studies provide direct biochemical evidence linking these important growth regulatory molecules to the mitogenic signalling cascade activated by growth factors ☐

Note added in proof We have also observed tyrosine phosphorylation of GAP in NIH3T3 cells transformed by oncogenes encoding non-membrane-spanning as well as membrane-spanning tyrosine kinases

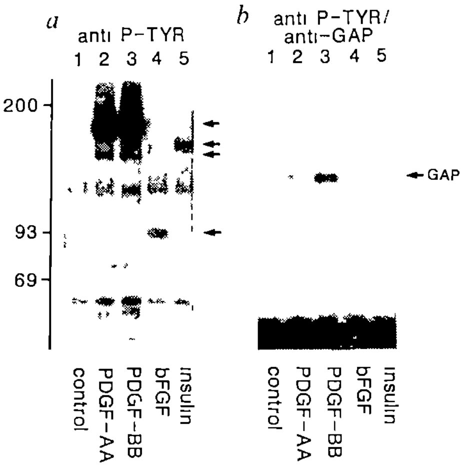

FIG 4 Anti-P-Tyr antiserum recovery of GAP in response to different growth factors *a*, Anti-P-Tyr antiserum immunoblot analysis of whole-cell lysates from unstimulated (lane 1) cells or cells treated for 10 min with PDGF AA homodimer (100 ng ml^{-1}, lane 2), PDGF BB homodimer (100 ng ml^{-1}, lane 3) basic FGF (200 ng ml^{-1}, lane 4), or insulin (100 μg ml^{-1}, lane 5) Tyrosine-phosphorylated bands induced by different growth factors are indicated by arrows *b*, Immunoblot of anti-P-Tyr antiserum-recovered proteins using anti-GAP peptide serum Anti-P-Tyr antiserum immunoprecipitates were prepared from cells treated as in *a* Methods are as described in Fig 1 Blots were exposed to film for 4 days

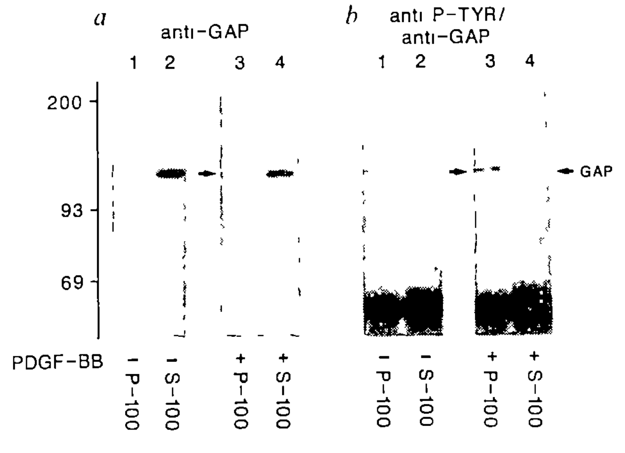

FIG 3 Subcellular localization of GAP following PDGF BB homodimer stimulation *a*, Anti-GAP peptide serum 638 immunoblot of protein extracts (40 μg per lane) from either particulate (P-100) or cytosolic (S-100) cell fractions Cells were either quiescent (lanes 1 and 2) or stimulated with PDGF BB homodimer for 10 min (lanes 3 and 4) *b*, Anti-GAP peptide serum 638 immunoblot of anti-P-Tyr antiserum-recovered proteins from subcellular fractions of unstimulated (lanes 1 and 2) and PDGF BB homodimer-stimulated (lanes 3 and 4) cells Blots were exposed to film for 5 days

METHODS After incubation in serum-free medium for 18 h, confluent NIH3T3 cells (3 × 100-mm plates) were either left untreated or stimulated with PDGF BB homodimer at 100 ng ml^{-1} for 10 min Cultures were then rinsed twice with cold PBS containing 1 mM Na_3VO_4, and then 0 75 ml hypotonic lysis buffer (20 mM HEPES buffer pH 7 4, 5 mM sodium pyrophosphate, 5 mM EGTA, 1 mM $MgCl_2$, 1 mM Na_3VO_4, 1 mM PMSF, in addition to 10 μg ml^{-1} aprotinin, leupeptin, and pepstatin) was added to each plate on ice Cells were collected by scraping into a Dounce homogenizer with a tight-fitting pestle and subsequently lysed with 40 strokes After centrifugation at 1000*g* for 5 min, the supernatant fraction was ultracentrifuged at 100,000*g* for 45 min The cytosolic (S-100) supernatant fraction was removed, and the insoluble pellet was resuspended and recentrifuged The resulting pellet (particulate fraction) was then solubilized in 1 ml P-Tyr lysis buffer (see legend to Fig 1) Cytosolic fractions were concentrated to 1 ml by ultrafiltration using Centricon-10 filters (Amicon) Under these conditions, cell protein recovery in P-100 and S-100 fractions were about equal Aliquots (40 μg) from each fraction were used for anti-GAP peptide serum immunoblot analysis For phosphotyrosine analysis, aliquots of each fraction containing 400 μg protein were first immunoprecipitated with anti-P-Tyr antiserum followed by immunoblotting with anti-GAP peptide serum as described in Fig 1 legend

Sequence-specific RNA binding by the HIV-1 Rev protein

Maria L. Zapp & Michael R. Green

Department of Biochemistry and Molecular Biology, Harvard University,
7 Divinity Avenue Cambridge, Massachusetts 02138, USA

THE human immunodeficiency virus type 1 (HIV-1) Rev protein acts post-transcriptionally to increase the amounts of the viral *gag–pol* and *env* messenger RNAs in the cytoplasm of infected cells[1 2]. The mechanism of Rev action is uncertain. Possibilities include an accelerating effect on the rate of export of its mRNA targets from the nucleus[3–6] and/or modulation of the splicing of pre-mRNAs (reviewed in ref 7) Both the *gag–pol* and *env* mRNAs contain a sequence that is required for responsiveness to Rev—the Rev responsive element, RRE[3,4,6,8]. Here we show that Rev is a sequence-specific binding protein, whose binding site is the RRE. This information should help to clarify the mechanism by which Rev acts.

RNA binding experiments were performed using extracts or fractions containing or lacking Rev expressed in *Escherichia coli* from plasmid pZ76-Rev This plasmid was constructed by inserting a *rev* complementary DNA clone into the the expression vector plasmid pRW76, introduced into *E coli* strain XA-90, and *rev* expression induced by treatment with isopropylthiogalactoside (IPTG) In XA-90 (pZ76-Rev) cells, IPTG specifically induced the expression of a polypeptide of relative molecular mass 18,000 (M_r 18K), which was not observed after IPTG treatment of non-transformed XA-90 cells (Fig 1*a*) An immunoblot analysis using a polyclonal α-Rev antibody confirmed that the IPTG-induced 18K polypeptide was Rev (Fig 1*b*)

An RNase protection-mobility shift assay was designed to test whether Rev binds to RNA The RNA binding substrate was an SP6-derived ^{32}P-labelled RNA containing sequences from the HIV-1 *Bgl*II-*Bam*HI fragment (positions 7,201-7,721, ref 9), which encompasses the RRE (Fig 2, bottom, pGEM-HIV1 RRE) After incubation of the ^{32}P-labelled RNA substrate in the *E coli* extracts, the reaction mixtures were extensively treated with RNases T1 and *A*, and ^{32}P-labelled RNA-protein complexes resolved on a native polyacrylamide-agarose gel

A protein in the Rev-containing extract bound to the RRE-containing ^{32}P-labelled RNA substrate (Fig 2) An RNAse-resistant ^{32}P-labelled RNA fragment of retarded electrophoretic mobility was present in the extract prepared from IPTG-treated XA-90 (p76-Rev) cells (lane 4), but not in extracts prepared from non-induced cells (lane 3), or extracts prepared from IPTG-treated XA-90 cells (lane 2) A partially purified Rev fraction (Fig 1*b*, DEAE, 0 2) also supported formation of the ^{32}P-labelled RNA complex (lane 6), whereas complex formation was not detected in a DEAE fraction that lacked Rev (Fig 1*b*, DEAE, 0 4, Fig 2, lane 5) The ^{32}P-labelled RNA complex was eliminated by addition of SDS (lane 7) or proteinase K (lane 8), indicating that it contained both RNA and protein Finally, the ^{32}P-labelled RNA-protein complex was not formed if th RNase was added before rather than after the addition of th Rev-containing extract (lane 8) Taken together these result indicate that a protein binds to the RRE-containing RNA sub strate and protects a region of it from RNase digestion

Formation of the RNA-protein complex is specific to a RRE-containing substrate An unrelated adenovirus RNA sub strate (MINX, lane 11), or an HIV-1 RNA substrate that con tains sequences upstream of the RRE (580, lane 10), did no

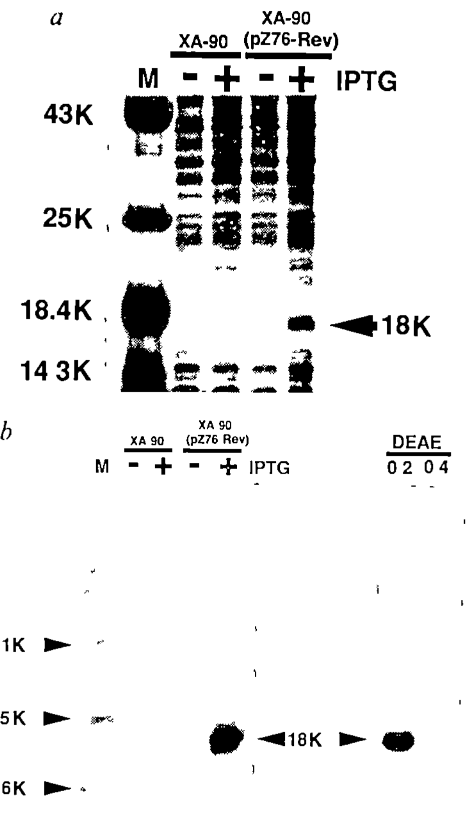

FIG 1 Detection of Rev synthesized in *E coli* *a*, Coomassie blue-stained 12 5% SDS-polyacrylamide gel of protein (~35 μg) from the various extracts Extracts were prepared from either XA-90 or XA-90 (pZ76-Rev) cells with or without IPTG treatment as indicated Migration of protein M_r standards is shown on the left The arrow denotes the IPTG-induced polypeptide in XA-90 (pZ76-Rev) cells of M_r ~18K *b*, Immunoblot analysis Protein (~3 5 μg) from the various extracts was fractionated on a 12 5% SDS-polyacrylamide gel, and Rev detected by immunoblotting using a polyclonal α-Rev antibody The unfractionated extracts (left) were identical to those used in *a* Chromatographic fractions from a DEAE-Sephacryl column loaded with an IPTG-induced XA-90 (pZ76-Rev) extract are shown on the right Migration of ^{14}C-labelled M_r standards (M) is shown on the left

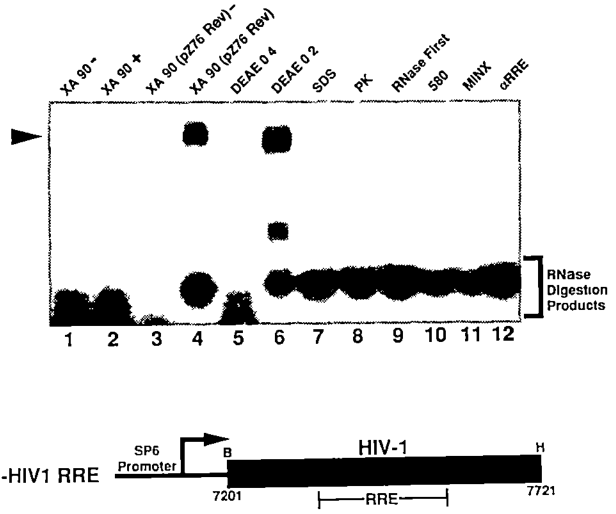
METHODS *a*, Plasmid pZ76-Rev was constructed by inserting the *Eco*NI–*Hin*dIII fragment from the plasmid pcREV (ref 17), which contains a *rev* cDNA clone, between the *Nco*I and *Hin*dIII sites of an *E coli* expression vector plasmid pRW76 (pRW76 is a derivative of the plasmid pLPK76-7, ref 18) The *Eco*NI site (position 6,005) is within the *rev* cDNA ATG translation initiation codon and was joined to the *Nco*I site of pRW76 to restore the translation initiation site and reading frame IPTG-induction and preparation of sonicated *E coli* extracts is described in ref 19 *b*, The α-Rev antibody was prepared by immunizing rabbits with an affinity-purified *E coli*-derived function protein containing Rev sequences encoded by plasmid pSVSX1 (ref 4) The α-Rev antibody (1 1,500 dilution) was incubated with the nitrocellulose for 1 h at 4 °C Antibody–antigen complexes were detected using ^{125}I-labelled protein A (NEN) and autoradiography DEAE fractions were prepared by loading an IPTG-treated XA-90 (pZ76-Rev) extract onto a DEAE-Sephacryl column in buffer A (ref 19) in 50 mM NaCl After collection of a flow-through fraction, the column was eluted with steps of 100 mM, 200 mM, 400 mM and 1 M NaCl Although all fractions contained significant amounts of total protein, immunodetectable Rev was present only in the 200 mM fraction pport formation of the RNA-protein complex Likewise, the rotein also did not bind to the antisense transcript of plasmid GEM-HIV1 RRE (α-RRE, lane 12)

To verify that the RNA-binding protein was in fact Rev, three dditional experiments were performed (Fig 3) First, the size f the RNA-binding protein was determined The proteins in a ev-containing extract were separated by preparative SDS-AGE The gel lane was divided into eight slices, the proteins luted from each slice, the SDS removed by acetone precipitation, and the precipitated proteins resuspended in 6 M guanidine ydrochloride to denature the polypeptide chains[10,11] After moving the guanidine hydrochloride by dialysis, each fraction as assayed for RNA-binding activity All of the RNA-binding ctivity was in the region of the SDS-polyacrylamide gel corresponding to an M_r of 18-20K (Fig 3*a*), the only fraction that ontained Rev (Fig 1*b*, and data not shown)

Next, we asked whether Rev was physically associated with he ^{32}P-labelled RNA substrate If so, an α-Rev antibody should bind to the ^{32}P-labelled RNA-protein complex and alter its electrophoretic mobility ^{32}P-labelled RNA-protein complexes were formed as described above Before loading the complexes on the gel, either the α-Rev antibody or a control pre-immune serum was added to the reaction mixtures (Fig 3*b*) As the amounts of the polyclonal α-Rev antibody added increased, the band corresponding to the normal ^{32}P-labelled RNA-protein complex diminished and concomitantly several bands of reduced electrophoretic mobility appeared By contrast, the addition of comparable amounts of a control pre-immune serum did not affect either the amount or the electrophoretic mobility of the normal ^{32}P-labelled RNA-protein complex



IG 2 Analysis of RNA binding by an RNase protection–mobility shift assay he standard RNA-binding reaction contained the plasmid pGEM-HIV1 RRE ^{2}P-labelled RNA substrate and extract prepared from IPTG-treated XA-90 pZ76-Rev) cells (lane 4) The main variation from this standard reaction is ndicated above each lane Lanes 1–9, plasmid pGEM-HIV1 RRE ^{32}P-labelled NA substrate Lanes 4 and 7–12, extract prepared from IPTG-treated XA-90 pZ76-Rev) cells Lanes 1 and 2, extract prepared from non-induced and PTG-induced XA-90 cells, respectively Lane 3, extract prepared from non-nduced XA-90 (pZ76-Rev) cells Lanes 5 and 6, DEAE (0 4 M) and 0 2-M ractions of an IPTG-treated XA-90 (pZ76-Rev) cell extract, respectively anes 7 and 8, identical to lane 4 except that 0 1% SDS or 0 4 μg proteinase , respectively, were added to the sample before loading on the gel Lane 9, similar to lane 4 except that the ^{32}P-labelled RNA substrates were ncubated with the RNases before addition of the extract Lane 10, HIV-1 580 RNA substrate Lane 11, adenovirus MINX RNA substrate[20] Lane 12, antisense transcript of plasmid pGEM-HIV1 RRE The position of the RNA–protein complex is indicated by the arrowhead The structure of the ^{32}P-labelled RNA probe run-off at the *Hin*dIII site (position 7,721) is shown below the autoradiograph Black box, HIV-1 sequences, B, *Bgl*II site, H, *Hin*dIII site The minimal HIV-1 RRE (positions 7,361–7,569) as defined in ref 3 is indicated

METHODS ^{32}P-labelled RNA probes were synthesized by *in vitro* transcription using SP6 or T7 RNA polymerase and full-length transcripts purified on a 5% denaturing polyacrylamide gel RNA binding reactions contained 10–20 μl extract or fraction, 2 μl ^{32}P-labelled RNA probe (36,000 Cerenkov c p m), and buffer A (ref 19) in a final volume of 25 μl Binding reactions were at 30 °C for 15 min, after which 2 5 U RNase T1 (Pharmacia) and 1 25 μg RNase A (Pharmacia) were added and incubation continued for 10 min The reaction mixtures were directly loaded onto a native 6% polyacrylamide (60 1 cross-linking ratio)–0 5% agarose gel The electrophoresis buffer was 100 mM Tris-HCl, pH 8 8, 50 mM glycine The 580 RNA substrate was synthesized from a plasmid in which the 580-nucleotide *Bgl*II–*Bgl*II HIV-1 DNA fragment (positions 6,621–7,200) was cloned into the *Bam*HI site of the plasmid pGEM3 (Promega) polylinker in the orientation such that the sense strand was transcribed using SP6 RNA polymerase

Finally, we investigated whether Rev could be directly detected in the RNA-protein complex The RNA-protein complex was resolved on a native gel, the band excised, the proteins resolved on a SDS-polyacrylamide gel, and Rev detected by immunoblot analysis The immunoblot (Fig 3*c*) confirmed that the 18K Rev protein was indeed present in the RNA-protein complex

These experiments show that Rev binds specifically to an RRE-containing RNA substrate To demonstrate that Rev bound to the RRE, various derivatives of the RNA substrate were analysed (Fig 4) The 208-nucleotide *Sty*I-*Sau*3AI fragment (positions 7,361–7,569) is the minimal sequence that enables a viral RNA to be affected by Rev (ref 3) Figure 4*a* shows the results of RNA binding experiments using 3′ deletion derivatives of plasmid pGEM3-HIV1 RRE Rev bound equally well to an RNA whose 3′ end was at the *Sau*3AI site (position 7,569) as it did to the original substrate whose 3′ end is at the *Hin*dIII site (position 7,721) But Rev did not bind to an RNA whose 3′ end was at the *Hin*fI site (position 7,540) or the *Alw*NI site (position 7,491) Thus, the 3′ boundary of the region required for Rev binding is within the RRE, between positions 7,540 and 7,569

To determine the 5′ boundary of the Rev-binding site, a comparable 5′ deletion analysis was performed (Fig 4*b*) Rev bound equally well to an RNA whose 5′ end was at the *Mbo*II site (position 7,312) as it did to the original substrate whose 5′ end was at the *Bgl*II site (position 7,201) But further 5′ deletion within the minimal RRE to the *Hae*III site (position 7,424) or *Alw*NI site (position 7,491) eliminated Rev binding Thus, the 5′ boundary of the region required for Rev binding is within the RRE, between positions 7,312 and 7,424

Our *in vitro* binding data is in excellent agreement with the results of a previous *in vivo* study[3], which defined a minimal RRE based on Rev function Deletions that abolish RRE function also prevent Rev binding Therefore the minimal RRE apparently corresponds to the minimal Rev-binding site The RNA region required for Rev binding is relatively large (minimally 116 nucleotides, from the *Hin*fI site to the *Hae*III site) Perhaps Rev binding requires an RNA structure that is formed by two or more non-contiguous RNA regions In fact, the RRE is within an RNA region predicted to have extensive secondary structure[3]

Relatively few sequence-specific RNA-binding proteins have been analysed and only one protein motif, the ribonucleoprotein (RNP) consensus sequence (reviewed in ref 12), has been shown to be involved in sequence-specific RNA binding[13] Rev does not contain an RNP consensus, indicating that its RNA-binding motif could be of a novel class The N-terminal portion of Rev is rich in arginine residues and mutations in this region can interfere with Rev function[14] It is tempting to speculate that this arginine-rich basic region contributes to the RNA-binding activity of Rev

Besides this arginine-rich region, Rev contains at least one other functional domain located near the C terminus[14] Our results imply that one of the functional domains of Rev corresponds to the RNA-binding region (presumably the basic region) The other functional domain(s) presumably provides an effector function, which could interact with a cellular com-

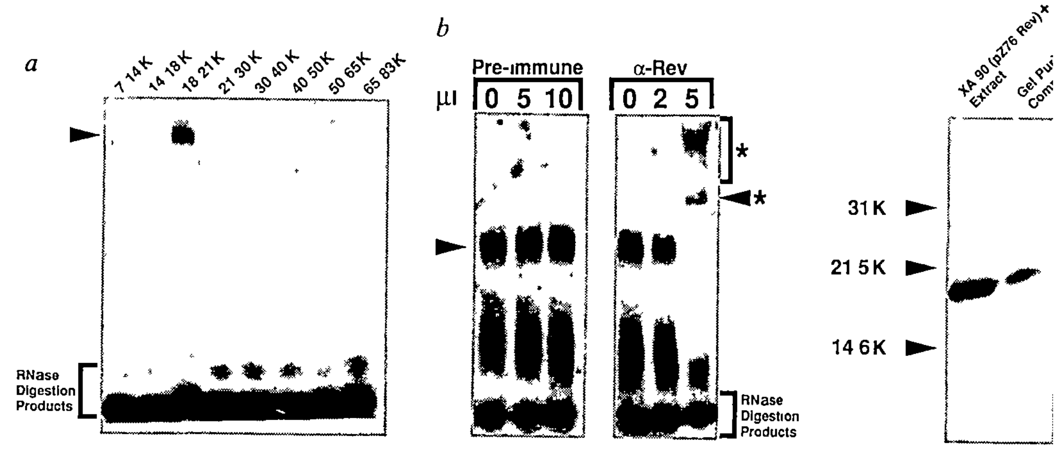


FIG 3 Rev is the RNA-binding protein *a*, Guanidine renaturation of RNA-binding activity Each RNA-binding reaction contained 20 μl of the gel-purified protein fraction indicated above the lane METHODS Extract (2 3 mg) prepared from IPTG-treated XA-90 (pZ76-Rev) cells was fractionated on a preparative 12 5% SDS-polyacrylamide gel The gel lane was divided into eight slices, each slice was diced using a razor blade, and soaked overnight at room temperature in 1 ml elution buffer[10] Polyacrylamide was removed by centrifugation, proteins precipitated by addition of five volumes of 100% acetone and incubation on dry ice for 3 h Precipitated proteins were collected by centrifugation, rinsed in 80% acetone-20% elution buffer without SDS, resuspended in 50 μl of 6 M guanidine hydrochloride-0 1% Nonidet P-40-0 1 M KCl and incubated overnight at room temperature Samples were extensively dialysed against buffer A (ref 19) *b*, An α-Rev antibody alters the electrophoretic mobility of the ^{32}P-labelled RNA-protein complex The type and amount (μl) of antiserum added to the reaction mixtures is indicated above each lane The position of the normal RNA-protein complex is indicated by the arrowhead on the left The positions of RNA-protein complexes of altered electrophoret mobility are indicated by the starred arrowhead and brackets on the rigt The faster-migrating complex is due to partial proteolysis of Rev in th particular extract *c*, Rev is present in the ^{32}P-labelled RNA-protein comple The ^{32}P-labelled RNA-protein complex resolved on a native gel was locate by autoradiography, the gel slice excised, and directly inserted into a lar of a 12 5% SDS-polyacrylamide gel Rev was detected by immunobl analysis using the α-Rev antibody as described in the legend to Fig 1*b*

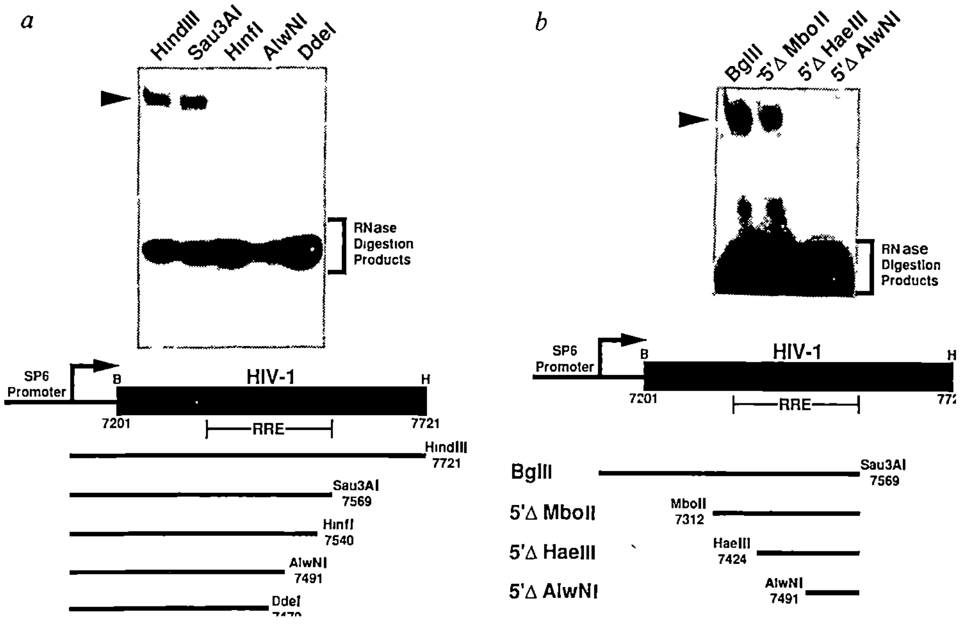

FIG 4 Delineation of the Rev-binding site *a*, 3′ deletion analysis Truncated ^{32}P-labelled RNA substrates were synthesized from the plasmid pGEM-HIV1 RRE DNA templates cleaved at the indicated restriction sites Each RNA binding reaction contained an identical amount of ^{32}P-labelled RNA substrate A schematic diagram of the ^{32}P-labelled RNA substrates is shown below the autoradiograph *b*, 5′ deletion analysis Each RNA-binding reaction contained an identical amount of ^{32}P-labelled RNA substrate A schematic diagram of the ^{32}P-labelled RNA substrates is shown below the autoradiograph
METHODS 5′ deletion constructs were prepared by inserting either the *Mbo*II-*Hin*dIII (positions 7,312-7,721), *Hae*III-*Hin*dIII (positions 7,424-7,721), or *Alw*NI-*Hin*dIII (positions 7,491-7,721) HIV-1 DNA fragments between the *Hin*cII and *Hin*dIII sites of plasmid pGEM4 (Promega) SP6-transcription templates were prepared by cleaving these constructs with *Sau*3AI

ponent involved, for example, in mRNA nuclear export or pre-mRNA splicing Some mutations within this C-terminal domain have a dominant-negative phenotype[14] A Rev protein that contains an RNA-binding domain but lacks the putative effector function would compete with wild-type Rev for binding to the RRE and thus have a dominant-negative phenotype

The HTLV1 Rex protein seems to function similarly to Rev (see refs 15, 16) It is therefore likely that Rex is also a sequence-specific RNA-binding protein Rex can functionally substitute for Rev in co-transfection experiments[15] This raises the possibility that Rev and Rex bind to the same RNA site even though they have no detectable amino-acid similarity ☐

Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

An Important New Title from Macmillan

Principles and Techniques of Electron Microscopy

Biological Applications

Third Edition

M A Hayat, Professor of Biology, Kean College, New Jersey, USA.

Principles and Techniques of Electron Microscopy is an essential tool for all biologists using electron microscopes - it is a textbook, a laboratory manual and a reference volume. It discusses in detail the biological principles governing the processing of biological specimens and step-by-step procedures used in the laboratory. Information is presented in the same sequence as it is needed in the laboratory and is illustrated wherever appropriate.

The third edition of this standard text on electron microscopy has now been thoroughly revised and updated, with the addition of two new chapters. Major features of this new edition are:

- New chapters on cryofixation and negative staining
- New and more effective illustrations
- More information on the principles and theory of methodology

November 1989 490 pp 246 x 189 mm

Pre-Christmas product selection

A gel elutor for extracting nucleic acids or protein, a cryopreservation system for freezing/thawing mouse embryos and a neurotoxicological evaluation service based on the leech brain are just a few of the products outlined below.

NEW from Bioproducts for Science, Inc. is a **mouse anti-rat natural killer cell monoclonal antibody** that recognizes and reacts with all rat NK cells, large granular lymphocytes and neutrophils (*Reader Service No. 100*). The mouse anti-rat NK cell mAb has applications in the study of transplant immunology and in studies requiring *in vivo* depletion of NK cells. The mAb is available in three forms: 5-ml vials of culture supernatant with 5 μg/ml of antibody; 0.25-ml vials of ascites with 1–2 mg/ml of antibody; and as a $F(ab')_2$ FITC conjugate in 1-ml vials containing 700 μg/ml of antibody. All products are supplied with a procedures guide.

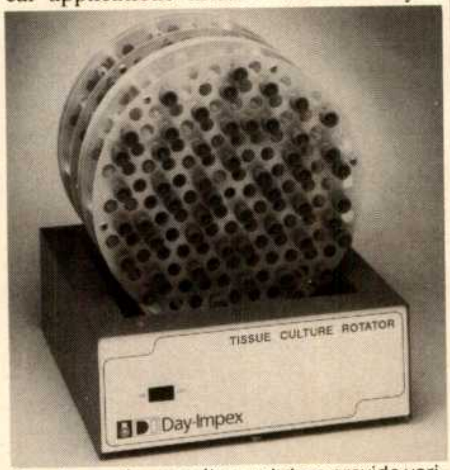
Handy helpers

According to Fisher Scientific, the Fisher Biotech Gel Eluter can simultaneously extract samples from up to six gel slices using a **vertical gel elution technique** (*Reader Service No. 101*). The vertical design of the apparatus is said to offer advantages over conventional horizontal elution methods by accelerating migration of the sample, minimizing electroconvection and reducing build-up around the seive pores. The elution column is divided by a porous frit into a sample chamber and removable recovery chamber. The frit acts as a physical barrier to the gel slice while allowing the eluted material to pass into the recovery chamber, to be drawn off by syringe. Fisher says, the eluter will recover virtually any nucleic acid or protein sample with a 75–100 per cent recovery efficiency. The apparatus will work with most power supplies and each elution column requires a current of 1–2 mA.

FisherBiotech Gel Eluter: designed for vertical gel elution.

The $295 (US) gel eluter can also be used as a tube gel isoelectric focusing apparatus. It can run up to 12 tube gels under identical conditions used in IEF analysis or as the first dimension separation in 2-D electrophoresis.

For the smooth, continuous **rotation of bottles and test tubes**, Day-Impex has introduced a new line of Tissue Culture Rotators (*Reader Service No. 102*). Typical applications include the monolayer culture of anchorage-dependent cells for increased production of, for example, monoclonal antibodies, viruses, enzymes and other secreted products. Four models of the bottle rotator are available which hold between two and ten bottles and operate at speeds of 0.5–8 r.p.m. A tachometer on the control panel provides a readout of rotational speed. The tissue culture test tube rotators are designed to operate in incubators up to temperatures of 60 °C. A single-drum rotator has a capacity of 84 25-mm tubes or 150 16-mm tubes and can operate at rotational speeds of up to 70 r.p.m. The tube capacity can be doubled by the addition of an extra drum. The angle of the drum is adjustable between 5° and 90° above horizontal. All rotator drums are constructed of enamel-coated stainless steel for corrosion resistance. Prices for the bottle and tube rotators range from £480–1,200 (UK).



Day-Impex tissue culture rotators provide variable speed and angle of rotation.

Save space in your fridge/freezer with the new plastic **square media bottles** from Nalge Co., which are now available in 30- and 60-ml sizes (*Reader Service No. 103*). The PETG square bottles do not break or shatter like glass and have O_2/CO_2 barrier properties that prevent outgassing and destructive pH shifts in the stored media, says Nalge. The transparent bottle and leakproof linerless closure are made of materials that are non-toxic and non-pyrogenic. Aseptic technique is facilitated by the deep closure and narrow-mouth design, and the pouring ring on the neck aids dispensing. Researchers can choose from three different resins for bottles that are autoclavable, chemical and temperature resistant. The 30-ml and 60-ml bottles are $81.60 and $105.60 (US), respectively, for a case of 96 bottles.

Space-saving square media bottles from Nalge.

In a spin

Measuring only 12 cm in diameter, the MC 200 NanoFuge **microcentrifuge** is, says Hoefer, ideal for applications requiring spinning at low *g*-forces (*Reader Service No. 104*). The $355 (US) NanoFuge can hold up to six 1.5- or 2-ml microcentrifuge tubes or, when fitted with an adaptor, will hold tubes as small as 0.25, 0.4 and

The MC 200: Hoefer's tiny microcentrifuge for spinning at low *g*-forces.

0.5 ml. Stated applications include spinning down droplets from caps and walls of microcentrifuge tubes, blood, urine and tissue centrifugation, and the sedimentation of bacterial cells. Closing the lid of the instrument initiates the spinning process and opening it stops it. The NanoFuge can operate at a maximum speed of 5,000 r.p.m. with a *g*-force of 200.

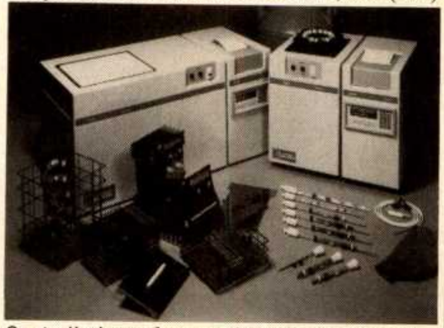
Scientific Equipment Design has launched a new generation of **refrigerated centrifuges** that employ solid-state refrigeration technology, eliminating the need for CFCs, bulky compressors or gas refrigeration (*Reader Service No. 105*). The £2,985 (UK) 20R high-speed microcentrifuge can be supplied with a large number of rotor options that will hold anything from 120 microtubes to six 25-ml tubes. The 20R can operate at maximum speeds of 11,000 r.p.m. The £3,796.50 (UK) 30R refrigerated benchtop centrifuge has a capacity of two litres and can operate at speeds of 3,000 r.p.m. or 5,000 r.p.m. if fitted with smaller rotors. Cooling is provided down to 2 °C and the temperature can be set to within 0.1 °C by the digital temperature display/control. According to SED, the bowl temperature should equilibriate within 10 minutes of switch-on. Safety features of the 20R and 30R include an automatic out-of-balance indicator and safety cut-out, dual-lid interlock and three-position brake.

Frozen assets

Transgenic Sciences, Inc. has developed Cryozyte — a **cryoprotectant system** designed for the long-term, low-temperature storage of mouse embryos (*Reader Service No. 106*). The procedure takes about an hour and permits the ultra-rapid cooling of mouse embryos without ice crystallization. Once preserved in Cryozyte, TSI says the embryos can be stored indefinitely in any standard liquid nitrogen containers that accommodate canes. Viable embryos are incubated in equilibrium medium and then loaded into plastic straws that are prefilled with vitrification medium. Embryos are recovered by thawing at room temperature, followed by incubation in dilution and rehydration media. The $235 (US) kit comes complete with straws, plugs, step-by-step protocol guide, and all the necessary solutions for the cryopreservation of 375 mouse embryos.

Cryopreserve mouse embryos with Transgenic Sciences' Cryozyte kit.

Two new **controlled-rate freezer units** — Kryo 10/16 and 10/1.7 — are available from Planar Biomed (*Reader Service No. 107*). The freezers consist of a benchtop controller with a separate and insulated freeze-chamber module which is filled by the programmed transfer of liquid nitrogen. The Kryo 10/16, costing $11,500 (US) for the basic unit, has a 16-litre capacity and is suitable for freezing blood bags, ampoules and straws. The $11,750 (US) Kryo 10/1.7 model has a smaller capacity but straws and ampoules can be placed both horizontally and vertically. The temperature range in both units is +40 °C to −180 °C with cooling rates variable between 0.01 °C per minute to −50 °C per minute. The microprocessor-based programmer monitors the chamber and sample temperature with platinum-resistance thermometers: any malfunctioning is indicated on the display. Up to ten sets of program parameters can be stored.



Controlled-rate freezers from Planar Biomed.

Jencons Scientific Ltd are the sole distributors in the UK for the Taylor-Wharton **cryostorage systems** — the K Series — where K denotes the storage capacity in thousands of 2-ml vials (*Reader Service No. 108*). The K Series consists of 3K, 8K, 17K and 27K units, although a 5K unit will be available in early 1990. The refrigerator units can be provided with dedicated inventory systems for both liquid- and vapour-phase sample storage. Automatic control options — alarm only, autofill or full automatic control — for monitoring the level of refrigerant are available for the 8K, 17K and 27K models. The modular design of the K Series allows several units to be connected up to a single liquid nitrogen source, while each can remain under independent control.

DNA extraction

Using **glass adhesion methods**, extract DNA from agarose, separate out unincorporated nucleotides, remove organic solvents, isolate DNA from minipreps and concentrate DNA with the USBioclean kit from USB (*Reader Service No. 109*). Based on the methods of Vogelstein and Gillespie, 2 μl of the glass powder v typically bind 1 μg of DNA with 80 p cent recovery of the starting material, sa USB. The $80.50 (US) USBioclean comprises glass powder suspension, N solution, concentrated rinse buffer, Tr Acetate-EDTA electrophoresis buff and pipette tips. It is unsuitable for DN extractions from acrylamide gels, but c be used for both low- and high-m agarose. DNA that has been extracted this method, which, USB says, tak about 20–25 minutes, can be used f restriction digests and other enzyma manipulation.

Perkin-Elmer Cetus is offering th Isogene kit for the **extraction and purific tion of DNA** (*Reader Service No. 110*). Th method uses a DNA binder, which, th company says, has a higher capacity tha the glass-milk variety — typically 5 μg DNA is bound using 10 μl of binde Recoveries of bound DNA of 80–95 p cent can be achieved after two elution with 20 μl of distilled water. Stated appl cations for Isogene include the extractio and purification of DNA from agaro gels, extraction of plasmids from lysate desalting and/or concentrating DN solution, separating DNA from enzym inhibiting impurities and the replacemen of conventional alcohol precipitation c column-based methods for DNA purifica tion. Isogene kits are supplied with DN binder, NaI solution, washer buffer con centrate — sufficient for 100 assays, say Perkin-Elmer.

Detection systems

Tropix, Inc. has introduced two new optical **luminometers** for use with an chemiluminescent or bioluminescen reaction (*Reader Service No. 111*). Th $4,500 (US) ILA 911 single-well counter i manually operated while the $12,500 (US ILA 912 is a fully automated system tha can process up to 220 tubes. Both instru ments are fitted with a 1.125-inch photon counting photomultiplier, which, Tropi says, has a 20,000,000 count per secon rate maximum and has a programmabl optical sensitivity selection. The spectra response range is 320–500 nm. Afte insertion of the tube in the countin chamber, background measurements optional injections, shutter apertur selection and integration are automatically sequenced. The built-in microcomputer includes immunoassay, kineti and DNA probe data reduction protocols and can store up to 30 user-definable protocols. Each luminometer is equipped with a thermal graphics plotter. External computers and data reduction systems can be linked up to the luminometer via the RS232 port.

For the simultaneous **separation of ionic, neutral or polar analytes**, Dionex Ltd recommends the CES 1 Capillary Electrophoresis System (*Reader Service No. 112*). The CES 1 features a fully programmable dual-polarity power supply with the choice of three control modes — volt, current or power — as well as multistep gradients in all three modes. Also featured are three automated injection modes: electromigration, gravity and pneumatic. A random-access 40-position autosampler provides automatic rinsing of vials and capillaries and buffer changing. Separation takes place in an open capillary using electrophoretic migration and electro-osmotic flow to separate and elute components past an on-column detector. The CES 1 can monitor absorbance at wavelengths between 190 and 800 nm, and a bandwidth of 6 nm ensures detection of samples with injection volumes in the order of 1–10 nanolitres, says Dionex. Programme parameters input via the instrument's keypad can be viewed on the video display and methods can be stored in the non-volatile memory. Hard copy is output in a chromatography-like format.

Capillary electrophoresis from Dionex.

The collaborative efforts of Intracel Ltd, Nikon and Newcastle Photometric Systems have produced the Epi Fluorescence Systems for **single and dual wavelength fluorochromes** (*Reader Service No. 113*). The Epi Fluorescent System is based on the Diaphot inverted microscope, a series of bolt-on accessories that include photon counters, excitation and emission filter changers, and control software that allows the detection and quantification of Ca^{2+}, H^+, Mg^{2+}, Cl^- and Na^+ within single cells. For dyes with dual emission characteristics, a beam splitter is used to separate the two wavelengths, and two photomultipliers are used to detect the wavelengths simultaneously. For dyes that require excitation at two wavelengths, filter changers are used in conjunction with a single photomultiplier system. The software provides control of the arc and wheel filter changers and calibration of the photomultipliers. Experimental data can be shown on the computer screen and stored on disc.

Catalogues and services

Over 100 new products are listed in the free 1990 Sigma Cell Culture **catalogue** (*Reader Service No. 114*). The 248-page catalogue lists Sigma's complete line of tissue culture products, including 35 new products for plant tissue cultures, liquid and powdered media, Hybri-max products, sera and sera replacements, cell culture-tested reagents, biochemicals and equipment. In addition to the product list, the catalogue includes an expanded section of technical information, including commonly used techniques, stability studies, a guide to antibiotic use, and instructions for supplementing liquid media.

Sigma's 1990 cell culture catalogue.

Trouble shoot procedures for transfer methods when using hybridization membranes from Micron Separations, Inc. with their latest **protocol guide** (*Reader Service No. 115*). The guide outlines procedures for Southern, Northern and Western blotting, colony hybridizations, plaque lifts, nucleic acid dot/slot blotting, alkaline blotting, and the use of biotinylated probes with MSI nylon and supported nitrocellulose membranes. The guide features two new sections: how to select an appropriate membrane to suit the transfer procedure and ways to reduce background during the transfer process.

Neuropharm Ltd are offering a **neurotoxicity evaluation service** using the leech brain as a model system (*Reader Service No. 116*). Toxicological screening of compounds has, until now, been based almost exclusively on mammalian studies. Neuropharm are using the simpler nervous system of the leech to carry out acute neurotoxicity tests, which include acute dose response, type of response, mechanism of ion channel and receptor response. Neuropharm, emphasizing the advantages of using the leech, point out that leech neurons are large, easily accessible and individually identifiable. They can be removed as a whole or in part, isolated for several hours and can be impaled with more than one microelectrode.

Neurotoxicity testing service using the leech brain, from Neuropharm.

Custom Immunology is BAbCO's new brochure that describes their **contract antibody developoment service** (*Reader Service No. 117*). The brochure outlines custom services and protocols provided by BAbCO for polyclonal antibody generation in small and large animals, hybridoma cell-line development, ascites fluid scale-up production of mAbs under GMP guidelines, GLP animal model and veterinary science studies. Other services include antigen preparation, protein isolation and purification, peptide-carrier conjugation, antibody fragmentation, biotinylation, enzyme and fluorescent labelling. ☐

These notes have been compiled by Diane Gershon, from information provided by the manufacturers. To obtain additional information about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

Can student numbers be doubled?

Richard Pearson

The reduced numbers of students in higher education likely to result from demographic changes in the 1990s wil have to be countered by changes in attainment and participation rates.

LAST month, the Employment column showed how the output of the UK higher education system has trebled over the past three decades and how this expansion continued even through the previous demographic downturn which started in the late 1960s.

The question for the 1990s is whether the present output of 120,000 graduates a year can be doubled over the next 25 years as suggested by the Secretary of State for Education.

As a starting point, it is important to recognize that while the decade is ending with shortages of graduates, particularly in technological subjects, a significant number of graduates are unemployed and about one in four say they are underemployed.

The demand for good graduates is expected to increase, although it is not possible to forecast precise numbers or the balance between subjects. If demand continues to grow as it has over the past decade, demand could be 30 per cent higher at the end of the century than it is today.

The number of new graduates is expected to increase by more than 5 per cent by 1992. These students are already on their courses. Thereafter the numbers will depend on staying-on rates in education, examination achievements and the attractions of higher education to the young, particularly women, and to vocationally qualified and mature entrants.

Changes

Without changes in these factors, demographic change alone within the social classes will reduce the number of entrants to higher education by 10 per cent over the period 1990–2000.

- If, however, educational attainment levels rise by a single percentage point, a rate of improvement faster than that achieved in the 1980s, then the number of entrants would be four percentage points higher.
- If the A-level attainment rate throughout the United Kingdom were to equal that in Scotland, the numbers would be 31 percentage points higher.
- If the attainment rates of social classes III to V rise to match those of social classes I and II, the numbers would be 65 percentage points higher.
- If women's participation matches that of men, the numbers should be seven percentage points higher.
- If the participation rate of the vocationally qualified rises to match that of A-level students, the numbers would be 11 percentage points higher.
- Finally, if the participation rate of mature students grows by 50 per cent, the numbers would be 15 percentage points higher in the year 2000.

Scenarios

These changes were combined into two scenarios to illustrate what might be achieved in the next decade[1]. The first — rising participation — assumes that attainment rates will rise faster than in the 1980s, participation rates will rise, the number of vocationally qualified entrants will double, the participation rates of mature students will rise by 50 per cent and student loans will not suppress student demand for higher education. Under this scenario, the number of entrants would be 33 percentage points higher in the year 2000.

The alternative scenario, 'constrained expansion', assumes that improvements in attainment rates will continue, but at a rate nearer than of the 1990s, employer competition for school leavers will reduce participation rates, the number of vocationally qualified will be stable and the mature participation rate will rise by 25 per cent. Under this scenario, all the main factors still show improvements on the 1980s, but the effect would be only just enough to counteract the demographic downturn, with student numbers in 2000 being the same as in 1990.

It can be seen that significant changes in attainment and participation rates will be required simply to counteract the demographic effect over the next decade.

To meet the Secretary of State's wish to double student numbers would require changes along the following lines: significant increases in staying-on rates in education at the age of 16 to ensure that A-level attainment rates rise from under 14 per cent to more than 20 per cent, which is almost the level in Scotland; A-level attainment rates of social classes II–V rising by a further half; female participation matching that of males; participation by the vocationally qualified rising significantly to reach the A-level rate; and the mature participation rate increasing by more than 50 per cent.

These represent big improvements on the rates of change seen in the past decad and would result in fewer young peopl being available for employment in th labour market.

Competition

Student demand for higher educatior may, however, be reduced by the growin competition between employers an higher education institutions for th reduced number of school-leavers. Man employers are improving schools liaison and training and career prospects, and are raising salaries in order to maintain school-leaver intakes. They are also widening their recruitment nets to include more women and re-entrants to the labour market. Thus there will be increasing competition to retain pupils in the education system, and to attract both traditional and nontraditional entrants into higher education. The introduction of student loans and a reduction in the size of the maintenance grant is also likely to reduce the short-term attraction of higher education.

The issue for policymakers in higher education, industry and government is how to stimulate student demand and how to organize higher education and provide it with resources to cope with much larger numbers.

Even if student numbers increase, it is likely, assuming that the economy continues to grow, that the demand for good graduates will exceed the supply and that shortages will continue, at least in the first half of the 1990s. Much of this demand will focus on the traditional young graduate with a reasonable class of degree and broad basic skills. Any increase in the supply will include an increasing proportion of nontraditional graduates who, while they may not be 'worse', will be 'different'. A challenge for students, higher education and employers will be to ensure that the attributes of the new supply and the nature of employer demand coincide, otherwise there will be a significant number of graduates who find it difficult to enter what they regard as suitable employment in the 1990s. ☐

COLD SPRING HARBOR LABORATORY

FACULTY POSITION
X-RAY CRYSTALLOGRAPHY

We seek applicants for a newly-created faculty position in the field of protein structure and function, particularly X-ray crystallography, which will expand an ongoing effort at Cold Spring Harbor. Current faculty members in this area include Dr. Jim Pflugrath, Dr. John Anderson and Dr. Jeff Kuret. The X-ray crystallography group will move into the new W.M. Keck Foundation Structural Biology Laboratory in 1991. Both senior and junior faculty positions will be considered.

Curriculum vitae and names of references should be submitted to:

Dr. Bruce Stillman

ROYAL PERTH HOSPITAL

An Equal Opportunity Employer

Senior Research Officer

Applications are invited for an NH & MRC funded position of Senior Research Officer within the Department of Clinical Immunology at Royal Perth Hospital. The appointment will be for up to five years with opportunity for promotion according to NH & MRC criteria. The project relates to regulatory factors relevant to autoimmune disease and immunodeficiency. A PhD or MD with experience in cellular immunology is required to complement others with experience in cloning and mapping of MHC genes. The appointee should be able to supervise a laboratory with several staff and students and will need to be capable of attracting competitive funding. The salary will range from $40,463 to $52,170 depending on qualifications.

APPLICATIONS BY THE 5TH JANUARY 1990 INCLUDING CURRICULUM VITAE, REPRINTS AND THREE PROFESSIONAL REFEREES SHOULD BE ADDRESSED TO PROFESSOR RL DAWKINS, DEPARTMENT OF CLINICAL IMMUNOLOGY, ROYAL PERTH HOSPITAL, BOX X2213, GPO, PERTH WA 6001, WESTERN AUSTRALIA.

The Foundation Deutsches Krebsforschungszentrum Heidelberg (German Cancer Research Center) is a National Research Center (Großforschungseinrichtung), mainly funded by the Federal Ministry of Research and Technology and by the state of Baden-Württemberg. About 1400 people work in the center including more than 250 scientists. At present the following postdoctoral positions are available for scientists trained in natural sciences or medicine in the following.

Papillomaviruses in malignant tumors

Dr. E.-M. de Villiers (Applied Tumorvirology)

The program entails research on the role of papilloma viruses in malignant tumors under special emphasis on pathogenetic aspects. Experience in molecular biological methods is desired.

Growth control of normal and malignant Lymphocytes

Prof. Dr. P.H. Krammer (Immunogenetics)

Research on the role of cell surface molecules in growth control of normal and malignant lymphocytes. Experience in cellular immunology, immunochemistry and/or molecular biology is desired.

Applicants should have a Ph.D or M.D. degree and must be younger than 32 years. Experience in the relevant fields is a prerequisite for a successful application. The contracts are limited to a maximum of 3 years with a net salary of about 56.000,-- DM per year.

Written applications with curriculum vitae copies of diplomas, list of publications and further information about research interests should be sent to our Personalabteilung within three weeks after publication.

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research
Physiological and Neural Mechanisms Group

BIOSTATISTICIAN/STOCHASTIC MODELLER

Applications are invited for a short-term (three-year) post-doctoral appointment to the scientific staff of the Laboratory of Mathematical Biology. The research, which will be under the supervision of Dr. T.B.L. Kirkwood (Head of Laboratory), will involve the design and statistical analysis of experiments in collaboration with other groups in the Institute. Candidates with experience of stochastic methods are particularly encouraged to apply as there are major opportunities for research using stochastic models in our work on DNA and protein sequences and on cell and virus population dynamics. Experience of biomedical research would be an advantage but is not essential as relevant training will be given.

The position is available immediately. Informal enquiries may be made by telephoning Dr. Kirkwood on 01-959 3666 Ext. 2294. The salary will be in the range £12,381 to £20,469 (starting salary dependent on experience) plus £1,650 per annum London Allowance. MRC Pension Scheme optional.

Applications including a curriculum vitae, list of publications and the names and addresses of two professional referees should be sent to **Mr. C.R. Russell, Administrative Manager, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA,** not later than 29th December, 1989, quoting reference number PMB/0711.

The MRC is an Equal Opportunities Employer. (2261)A

NATIONAL INSTITUTES OF HEALTH

POSITIONS FOR STAFF FELLOWS (TENURE TRACK) AND POST-DOCTORAL FELLOWS

I. **TRANSGENIC MICE** - Studies involving the genes of HSV, HIV, EBV, receptors, and hormones; pathogenesis of viral infections and endocrine diseases.

II. **POLYREACTIVE ANTIBODIES/$CD5^+$ B CELLS** - Mechanism of polyreactivity; production and characterization of human monoclonal antibodies; biology of $CD5^+$ B lymphocytes.

III. **AUTOIMMUNE DISEASES** - Cloning, expression and characterization of autoantigens involved in insulin-dependent diabetes mellitus, lupus erythematosus, rheumatoid arthritis, and Graves' disease.

Positions available immediately. Experience in molecular biology desirable. Growing program with opportunity for Staff Fellows to have technical and/or post-doctoral support. Salary commensurate with experience (range $25,000 to $50,000 per year). Send Curriculum Vitae and names of references to Dr. Lois Salzman, Deputy Director, Intramural Research Program, National Institute of Dental Research, National Institutes of Health, 9000 Rockville Pike, Building 30, Room 121, Bethesda, MD 20892.

HOPE HOSPITAL

Applications are invited for these posts on a three year project, funded by the Sir Jules Thorn Charitable Trust.

1) **POSTDOCTORAL RESEARCH ASSOCIATE**: to investigate interactions between second messenger pathways in cultured human colonocytes and their role in regulating epithelial secretion. Experience in one or more of the following areas would be an advantage: epithelial transport mechanisms, cellular signalling, the application of single cell fluorescence techniques. Salary on the Research IA scale (£10,458-£16,665 p.a.) according to qualifications and experience.

2) **RESEARCH TECHNICIAN**: to join a group investigating the intracellular regulation of intestinal secretion using cultured epithelial cell lines. Practical experience in mammalian cell culture is desirable though not essential. Salary on the University Technician 4/5 scale (£8,645-£10,632 p.a.) according to qualifications and experience.

Applications, including a full curriculum vitae and the names and addresses of two referees, should be sent to **Dr G. Warhurst, Department of Medicine, Clinical Sciences Building, Hope Hospital, Salford M6 8HD** (061 789 7373, Ext 4403) from whom further information can be obtained. Closing date January 5th, 1990. The University is an equal opportunites employer. (2250)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)

BIOCHEMICAL PHARMACOLOGIST

SENIOR RESEARCH OFFICER

Applications are invited from postdoctoral scientists, for the post of senior research officer. The research is funded by a Programme Grant from the Wellcome Trust and relates to the function of G-proteins in signal transduction. A background in biochemistry, pharmacology or a related subject is essential, and experience in the field would be an advantage. The position is available to applicants from all EEC countries, and the salary will be in the range of £12,381 – £14,703 (plus £1,650 London Allowance). The post is available to end of October 1992 in the first instance. Informal enquiries should be made to Professor J MacDermot, Department of Clinical Pharmacology (01-740 3219).

Application forms and further details are available on request from the **Personnel Officer, Royal Postgraduate Medical School, Hammersmith Hospital, Du Cane Road, London W12 0NN. Please quote ref: AEU8. (tel: 01-740 3204).**

(2267)A

JAMES COOK UNIVERSITY OF NORTH QUEENSLAND
Townsville, Australia

MECHANICAL ENGINEERING

In order to meet the demands of continuing technological development in the North Queensland region, James Cook University is expanding its two-year feeder course in Mechanical Engineering to a full four-year degree program. The third year of the course was offered for the first time in 1989 and the fourth year will be offered in 1990.

The undergraduate program that is being developed is innovative in a number of ways. The two senior years of the course, for example, are largely project-oriented and have a strong emphasis on engineering design, contemporary technology, and the development of entrepreneurial and management skills.

Research and consulting activities will focus on the special problems and unique opportunities presented to industry in the tropics and in North Queensland in particular. Existing industries in the region such as agriculture, mining and manufacturing are being supplemented with high-technology ventures in fields such as marine technology, energy technology, tourism and recreation and aerospace engineering.

Applications are invited for the

FOUNDATION CHAIR IN MECHANICAL ENGINEERING

Applicants must have appropriate academic qualifications and a demonstrated ability to implement an innovative program in mechanical engineering education, together with an international reputation for research and scholarship.

The appointee will be expected to provide academic leadership and to liaise closely with local industry in generating co-operative research and teaching programs.

A Division of Mechanical Engineering is currently located in the Department of Civil and Systems Engineering, but a separate Department of Mechanical Engineering will be established not later than 1 July 1990. The appointee will be expected to take up duty as soon as possible after appointment.

The salary for Professor is A$65,837 a year.

Consultative and other outside paid work is encouraged, and the University's policy on the matter is generous.

Reference No. 89205.

Further particulars and application forms are available from **Appointments (37251), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF**, or from the **Registrar, James Cook University of North Queensland, Townsville, Qld. 4811, Australia,** with whom applications close on *31 January 1990*. (W6785)A

The Norwegian Research Council for Science and Humanities (NAVF) invites application from

SENIOR SCIENTIST IN VIROLOGY

for the position of research leader at the National Centre for Research in Virology in Bergen, Norway. The Centre of Virological Research is associated with the Virus Laboratory in the Department of Microbiology and Immunology and with the Center of Biotechnology of the School of Medicine, University of Bergen. The research leader will be responsible for implementation of an education and research development programme outlined by the Council for Medical Research under NAVF. He/she will be affiliated with the University of Bergen through a professorship position and will have excellent facilities to conduct own research, both independent and collaborative, and to build up her/his own research group.

The centre will have excellent laboratory facilities, housed together with the Virus Laboratory and the Center of Biotechnology in a new high technology centre to be opened in late 1990. Present research activities in virology are primarily concentrated on molecular biological and immunological aspects of retrovirus/HIV and herpes simplex virus infections in collaboration with research groups in UK and USA. Four senior and 6-8 junior scientists are connected to these projects in addition to those currently working at the centre.

It will be required that the research leader has broad scientific experience in virology with emphasis on molecular virological research relevant to human medicine. Significant experience in teaching and in research supervision at pre- and postdoctoral levels is mandatory.

The salary will be determined according to qualifications and experience.

For further information concerning the position write to **Professor Gunnar Haukenes, National Centre for Research in Virology, Armauer Hansen Building, N–5021 Bergen, Norway.**

Applicants should send their curriculum vitae and list of publications together with a description of their plans for the research activity, to Professor G. Haukenes, address as above, by January 15, 1990.

(W6788)A

CELL BIOLOGY
DEVELOPMENTAL NEUROBIOLOGY

Two senior level faculty positions
Department of Biology
University of California, Riverside

The Department of Biology, University of California, Riverside, invites applications for two openings at the senior level. One is in cell biology, at the Associate or Full Professor level; the other is in developmental neurobiology at the Full Professor level. The appointments will be effective July 1, 1990. Applicants should have an active research program, and an established reputation with a proven record of competing successfully for extramural funding. Demonstrated interest and ability in teaching is sought. Salary will be competitive and will depend on qualifications and experience. Modern research space and access to major equipment such as TEM, SEM, and staffed biotechnology and analytical chemistry instrumentation facilities are available.

CELL BIOLOGY

We are interested in all areas of research in cell biology. Preference will be given to scientists applying modern molecular approaches to the study of the cell and with interests in: cell/cell interactions, protein sorting and assembly, cytoskeletal structure and function, or extra-cellular matrix. Applications should be received by January 15, 1990. Please send *curriculum vitae*, summary of research and teaching interests, and arrange to have 3–5 referees send letters to: **Cell and Molecular Biology Search Committee, Department of Biology, University of California, Riverside, CA 92521.**

DEVELOPMENTAL NEUROBIOLOGY

Acceptable areas of resaerch include, but are not limited to, gene regulation and expression during neural development, neural differentiation and the development of integrative mechanisms, synaptogenesis, regeneration, mechanisms of learning and memory, and analysis of neural connectivity in response to environmental conditions, hormones or other factors. The successful candidate will be expected to assume a leadership role in the interdepartmental Neurobiology Program. Applications should be received by January 15, 1990. Please send *curriculum vitae*, summary of research and teaching interests, and arrange to have 3–5 referees send letters to: **Develpmental Neurobiology Search Committee, Department of Biology, University of California, Riverside, CA 92521.**

The University of California is an Equal Opportunity/Affirmative Action Employer and minority and female candidates are encouraged to apply. (NW4673)A

University of Utrecht

FACULTY OF VETERINARY MEDICINE

The Faculty of Veterinary Medicine of the University of Utrecht, The Netherlands, invites applicants for the position of

vac.nr. 70035

Full Professor in Parasitology

Applicants are expected to meet the following requirements:
- general and specific knowledge of parasitic infections and diseases in domestic animals, including parasitic zoonoses;
- expertise in molecular-biological, biochemical and/or immunological aspects of host-parsite relationships;
- experience in research management;
- experience in teaching;
- willingness to collaborate with other disciplines;
- willingness to serve on faculty boards and committees.

Candidates should:
- be a graduated veterinarian, medical doctor or (molecular)biologist;
- possess a Ph.D. or equivalent academic degree;
- be specialized in parasitology as evidenced by publications of high standard;
- be willing to learn Dutch within a reasonable period of time.

Further information is available on request.

The salary will be determined according to the experience of the applicant.

Application, accompanied by a full curriculum vitae and a list of publications, or suggestions of suitable candidates, should be confidentially sent to:

Prof. dr. Simon G. van den Bergh, dean, Faculty of Veterinary Medicine, P.O. Box 80.163, 3508 TD Utrecht, the Netherlands.

With equally qualified applicants preference will be given to woman.

(W6789)A

CELL AND MOLECULAR BIOLOGY POSITION:

The Department of Biological Sciences and the Center for Gene Structure and Function is recruiting for two positions for Cell or Molecular Biologists as tenure track faculty members. Appointment at any professional rank is possible depending on the qualification of the successful applicant. Successful candidates will be expected to establish an independent research program and to participate in team-taught courses in their area of research at the undergraduate and/or graduate level. Suitable start-up and relocation funds are available. Send curriculum vitae, a statement of research interests and names of references to: **Dr. Joseph S. Krakow, Chairman, Search Committee, Department of Biological Sciences, Hunter College, City University of New York, 695 Park Avenue, New York, NY 10021.** Hunter College is committed to participation in science at all levels by minorities and women.

(NW4693)A

CONDENSED MATTER EXPERIMENTAL PHYSICISTS

COLUMBIA UNIVERSITY DEPARTMENT OF PHYSICS

The Department of Physics of Columbia University is searching for outstanding condensed matter experimental physicists at the assistant professor level.

The successful candidates will be provided with startup funds to suit the requirements of their research programs. There is no restriction on the subfield that will be considered. Tenure positions will be available for some of the physicists in this program who develop truly outstanding research programs and who also demonstrate excellent teaching skills. We will also consider applications, at this time, from more senior experimental condensed matter physicists who presently have the qualifications for a tenure position.

Finally we will consider applications from small, established, highly successful groups of experimental physicists who might be interested in moving as a group to Columbia. These positions will remain open until they are filled. Persons or groups interested in being considered for these positions should send their curriculum vitae, publication list, and a statement of their research interests to:

Professor S. Nagamiyn
Condensed Matter Search Committee Chairman
Department of Physics
Columbia University
Box 3 Pupin
New York, N.Y. 10027.

They should also arrange to have, at least three letters of recommendation sent to the same address.

Columbia University is an equal opportunity-affirmative action employer. Women and members of minority groups are encouraged to apply for these positions. (NW4624)A

UNIVERSITY OF GLASGOW

CHAIR OF ARCHAEOLOGY

Applications are invited for the Chair of Archaeology in the University of Glasgow which fall vacant on 1st October, 1990 on the retiral of Professor Leslie Alcock.

The principal research and teaching interests of the Department of Archaeology lie in North-West Europe, without chronological limits, but with a special interest in Britain and Ireland. There is a strong commitment to archaeological science; and both the practical and theoretical aspects of archaeology feature strongly in the Department's teaching and research.

Further particulars may be obtained from the **Academic Personnel Office, University of Glasgow, Glasgow G12 8QQ,** where applications (3 copies; 1 copy in the case of overseas applicants), giving the names and addresses of three referees, should be lodged on or before 15th January, 1990.

In reply please quote Ref. No. 6774. (2271)A

RESEARCH FELLOW

(Anthelmintic Pharmacodynamics)

A$31,525-A$38,567

The CSIRO Division of Animal Health, Glebe, NSW Australia is seeking a research fellow for a term of three years to undertake research to characterise the relationship between molecular structure of antiparasitic agents (eg. benzimidazoles) and effects on absorption, gastric secretion and recycling of these compounds to the gastrointestinal tract of sheep.

Applicants should be self motivated and possess a Ph.D degree or equivalent qualifications in physiology and pharmacology.

Applications quoting reference No. KGL14 and the name/address of two professional referees, to the

McMaster Laboratory,
Private Bag No. 1,
P.O. Glebe, NSW Australia 2037
Fax: (02) 692 8561
by 16 February 1990.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W6794)A

EAST BIRMINGHAM
HEALTH AUTHORITY

EAST BIRMINGHAM
HOSPITAL – REGIONAL
CYTOGENETICS
LABORATORY

PRINCIPAL CLINICAL CYTOGENETICIST

pplications are invited for the st of Principal Clinical Cytoge- ticist in the Regional Cytogene- cs Laboratory based at East irmingham Hospital. This la- oratory provides a comprehen- ve cytogenetic service for a popu- tion of around 2.6 million. The ain duties of the Principal Cyto- eneticist will be related to the evelopment and running of the ytogenetic services, but facilities r research exist by collaboration ith Cytogenetic and Molecular enetic research groups within e Department.

Informal enquiries are welcome nd application forms may be ob- ined by contacting Professor Maj ulten, Regional Genetic Ser- ices, East Birmingham Hospital, ordesley Green East, Birming- am B9 5ST. Tel. 021 766 6611 xt. 2450.

Closing Date: 29th December 989. (2279)A

Ciba-Geigy is a major pharmaceutical company with an active interest and commitment to molecular biology. The Molecular Biology Department forms part of the Biotechnology Section located in the Company's main research facility in Basle, Switzerland. Applications are invited for a position as

Molecular/Cell Biologist

as research scientist in the Molecular Biology Department. The successful candidate will join a well-established unit and assume responsibility for a laboratory involved in developing and applying molecular/cell biology techniques for the identification and expression of new proteins of potential therapeutic/pharmaceutical interest.

We are seeking to recruit an independent, innovative research scientist with a Ph.D. and at least 2-3 years postdoctoral experience, who is motivated to work effectively in a highly-interactive, multidisciplinary research environment. Preference will be given to candidates with expertise in molecular biology who have had additional training in mammalian cell biology and/or immunology.

Applications, including a c.v., a summary of relevant research background and the names of two referees should be sent under ref. "Nature 2871" to **H. Schmid, CIBA-GEIGY Ltd., Personnel Department, P.O. Box, CH-4002 Basle.** (W6790)A

CIBA–GEIGY

Postdoctoral Training — Insect Molecular Biology

Two postdoctoral positions are available for studies on the development of recombinant baculoviruses for biological control of lepidopteran pests and the establishment of methods for silkworm embryo transformation. Candidates should not have more than two years of previous postdoctoral training and should have experience with recombinant DNA methodology. Annual starting stipends $22,000-24,000, depending on qualifications. Applications containing curriculum vitae, a brief summary of previous training experience and research goals, as well as names and addresses of three referees should be sent to:

Dr. K. Iatrou, Department of Medical Biochemistry, Faculty of Medicine, The University of Calgary, 3330 Hospital Drive N.W., Calgary, Alberta T2N 4NI, Canada.
(NW4687)A

PLANT ECOLOGIST

Tenure-track Assistant/Associate Professor position starting 1990-91 academic year. Candidate must have a strong field orientation and to bring modern approaches and techniques to research on terrestrial problems in Hawaii. The Botany Department's commitments include the investigation of mechanisms in the ecology and evolution of Hawaiian ecosystems and species. Responsibilities include research, teaching and service; courses could include introductory botany or biology, upper-division ecology and a specialized graduate course. Send curriculum vitae, reprints, statement of research and teaching interests and names of three referees to: **Chair, Ecology Search Committee, Botany Department, University of Hawaii at Manoa, 3190 Maile Way, Honolulu, HI 96822.** Closing date for receipt of applications: February 15, 1990. Inquiries accepted by FAX: 808-943-0380. An Equal Opportunity/Affirmative Action Employer. (NW4705)A

THE UNIVERSITY OF ADELAIDE
South Australia

invites applications from both women and men for the following position:

RESEARCH ASSOCIATE/RESEARCH FELLOW IN BIOCHEMISTRY

(Ref: 6925) in the DEPARTMENT OF BIOCHEMISTRY, to work on the molecular analysis of barley yellow dwarf virus in relation to the Yd2 resistance gene of barley. The general approach is to characterize strains of the virus which can and cannot overcome the natural resistance provided by this gene. Data obtained are required for the rational development of protecttion measures against this important virus of cereals.

Applicants should have, or be about to complete a Ph.D. and should have significant experience in molecular biology, preferably in the manipulation of nucleic acids. Experience in plant viruses is desirable but not essential.

The position is funded by the Australian Research Council and is available from 1 January 1990, for up to three years.

Further information concerning the duties of the position may be obtained from Professor R.H. Symons, Department of Biochemistry, telephone (08) 228 5354, Fax. (61 8) 224 0464.

INFORMATION about the general conditions of appointment and selection criteria may be obtained from the Senior Assistant Registrar (Personnel) at the University or from Appointments (37220), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

SALARY per annum: Research Associate A$27,953 × 5 — A$31,808; Research Fellow A$32,197 × 7 — A$41,841.

APPLICATIONS, IN DUPLICATE quoting reference number 6925 and giving full personal particulars (including whether candidates hold Australian permanent residency status), details of academic qualifications and names and addresses of three referees should reach the Senior Assistant Registrar (Personnel) at the University of Adelaide, GPO Box 498, Adelaide, South Australia, 5001, (Telex UNIVAD AA 89141, Facsimile 61 8 224 0464) not later than **8 January 1990**.

The University reserves the right to make enquiries of any person regarding any candidate's suitability for appointment, not to make an appointment or to appoint by invitation.

THE UNIVERSITY OF ADELAIDE IS AN EQUAL
OPPORTUNITY EMPLOYER (W6786)A

dkfz

Position in Classical and Molecular Cytogenetics

(headed by M. Schwab)

A position is available to study genetic contributions to human cancers. Our scientific activities address two subjects:

1. Identification and definition of genetic alterations in solid human cancers, in particular colon cancer and neuroblastoma.
2. Identification of the molecular basis of the regulation and function of the gene MYCN.

The successful candidate must have a Ph.D., preferencially at least two years of postdoctoral training and is expected to develop a vigorous research program addressing one of the two subjects, depending on his scientific interest.

The initial appointment will be for 2 years, salary is according to experience on the BAT scale. Applications should include a list of publications, a curriculum vitae and the names and addresses of two referees.

For details contact:
M. Schwab,
Deutsches Krebsforschungszentrum,
Institut für Experimentelle Pathologie,
Im Neuenheimer Feld 280,
D.6900 Heidelberg Phone: 06221–484 220 (W6798)A

UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY

DEPARTMENT OF NEUROPATHOLOGY

AIDS RESEARCH RESEARCH WORKER

Applications are invited for the above post from suitably qualified scientists. The Research Worker is required to set up and maintain a national data base of laboratory, clinical and pathological information in relation to HIV infection and the nervous system. The Research Worker is expected to collaborate with basic and clinical neuroscientists. The candidate should preferably have some expertise in the use of data base and personal computers; further training can be obtained. The post will provide excellent opportunity for personal research.

The project is supported by the MRC for five years.

Salary is in the range £9,816–£12,381 pa plus £1,650 pa London Allowance.

Further information can be obtained from Professor P L Lantos on 01–703 5411 Ext 3272. A curriculum vitae, with the names of two referees, should be sent to the **Personnel office, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF.** Closing date 28 December 1989. (2243)A

M.I.T. Department of Biology

Faculty Positions in Genetics and Development

Candidates are sought for two tenure track positions at the level of Assistant Professor. Candidates should have significant research experience in either Genetics or Development. The responsibilities of this position include conduct of an active research program and participation in the teaching program of the Department.

Applicants should send a curriculum vitae and a summary of proposed research, and arrange to have letters sent from three scientists who can provide an evaluation of the candidate's accomplishments and future potential for both research and teaching. Applications and letters should be sent to:

Chairman, Genetics and Development Search Committee
c/o Room 56-511, Dept. of Biology
Massachusetts Institute of Technology
77 Massachusetts Avenue
Cambridge, Massachusetts 02139

M.I.T. is An Equal Opportunity/Affirmative Action Employer

(NW4698)A

MICROBIOLOGIST ASSISTANT, ASSOCIATE, OR PROFESSOR

The Department of Microbiology, University of California at Davis invites applications for an 11-month, tenure-track, open rank position from candidates who have demonstrated excellence in microbiological research. The candidate will join a strong, supportive and growing Department with strength in diversity, physiology and genetics. Teaching responsibilities include graduate and/or undergraduate courses in bacterial physiology and genetics. Please send a curriculum vitae, selected publications, a statement of proposed research, a description of teaching experience and interests, and the names of three references to: **Dr. J. C. Meeks, Chair, Physiology/Genetics Search Committee, Department of Microbiology, University of California, Davis, CA 95616.**

The position will remain open until filled; however, to be assured of consideration, applications should be received by February 1, 1990.

The University of California is an Affirmative Action/Equal Opportunity Employer. Women and Minorities are encouraged to apply. (NW4597)A

DANA-FARBER CANCER INSTITUTE HARVARD MEDICAL SCHOOL

Professor of Biological Chemistry and Molecular Pharmacology

Dana-Farber Cancer Institute (DFCI) and Harvard Medical School are seeking a Professor of Biological Chemistry and Molecular Pharmacology with a primary research interest in the molecular biology of gene regulation as it relates to the differentiation of mammalian somatic cells. The candidate should be a distinguished investigator, and will become a member of the new Division of Cell and Molecular Biology at the DFCI. The successful candidate will be expected to carry out a strong basic science research program, and participate in the teaching of medical and graduate students in the fields of cell and molecular biology.

Harvard University is committed to increasing representation of women and minority members among its faculty and particularly encourages applications from such candidates.

Candidates should send curriculum vitae, statement of research interests, and names of three references to:

DAVID M. LIVINGSTON, M.D., PROFESSOR OF MEDICINE, DANA-FARBER CANCER INSTITUTE, 44 BINNEY STREET, BOSTON, MA 02115.

Harvard Medical School and Dana-Farbar Cancer Institute are Affirmative Action-Equal Opportunity Employers. (NW4681)A

POSTDOCTORAL POSITION AT LOMA LINDA UNIVERSITY IN SOUTHERN CALIFORNIA

Ph.D. in one of the Biological Sciences is sought to conduct research on in vivo studies of bone metabolism in a large multi-disciplinary laboratory. Position has potential to develop into a permanent position (i.e., 3 years of successful performance will qualify the candidate for a tenure-track academic position). Experience in bone metabolism and U.S. citizenship is desirable but not required. Salary and Benefits Competitive.

Please send C.V., transcripts and 3 letters of recommendation to: **David J. Baylink, M.D., Chief, Mineral Metabolism (151), J.L. Pettis Veterans Hospital, 11201 Benton Street, Loma Linda, CA 92357.**

(NW4674)A

Institute for Small Animal Science P.O. Box 280, 3100 Celle, F.R.G.

Molecularbiologist Postdoctoral Position

Applications are invited from suitably qualified Postdoctoral Molecularbiologist to work in the Research Unit Physiology on an exciting project on the Ontogeny and Regulation of gene expression in the prenatal neuroendocrine brain. The position is funded by the German Research Foundation (DFG) for initially two years (extension for another two years possible) and is immediately available.

Please send CV, list of publications and the names of two referees to Dr. R. Grossmann at the above address by 31st December 1989. (W6791)A

A leading pharmaceutical Company
is seeking a

HEAD OF THE DEPARTMENT OF DOWNSTREAM PROCESSING PROTEIN CHEMISTRY

for its R. & D. Department
based in Milano — Italy

We require a Scientist (PhD level) to lead a group of 16–18 scientists and technicians involved in the purification of a number of recombinant proteins, scaling up of these procedures and eventually pilot production.

The ideal candidate will have at least 2—3 years post doctoral experience in an academic or industrial environment.

Spoken English is an important requirement.

We offer a competitive salary and encourage career development.

Sintex

Candidates should send a C.V **with Ref. A—1756 evidenced on the envelope** to: SINTEX S.r.l. – 20146 MILANO – Via Frua 22 – ITALY (W6792)A

UNIVERSITY OF STIRLING
BIOLOGICAL AND MOLECULAR SCIENCES
POST DOCTORAL FELLOW

A position is available from 1 March 1990, to work on a three-year AFRC funded project concerned with the molecular biology of anther development. Salary will be on the Research IA scale £10,458 to £16,665 pa.

Applications are invited from biochemists/molecular biologists, which should include full c.v. and names and addresses of two referees. These should be sent by 20 December 1989 to **Dr M J North, Department of Biological and Molecular Sciences, Stirling University, Stirling FK9 4LA, tel no 0786 73171 ext 2083,** from whom further particulars are available on request. (2260)A

UM

The University of Manitoba
Faculty of Science

MOLECULAR BIOLOGIST

The department of zoology, University of Manitoba has a tenure track position for a Molecular Biologist to start September, 1990. Salary is dependent on qualifications and experience. Applicants must have a Ph.D. with postdoctoral experience in development, evolution, or genetics. Promising applicants from other areas of metazoan molecular biology are not excluded. Responsibilities include undergraduate and graduate teaching and developing an independent, vigorous research program. Start-up support is available and opportunities exist for collaborative research. Both women and men are encouraged to apply. In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents. Applicants must submit a c.v., description of research interests, representative reprints and names of at least 3 references by March 31 to: **Dr. J.H. Gee, Zoology Dept., Univ. of Manitoba, Winnipeg, MB Canada R3T 2N2.** (NW4700)A

SIMON FRASER UNIVERSITY
CHAIR OF THE DEPARTMENT OF BIOLOGICAL SCIENCES

Applications and nominations are sought for the position of Chair of the Department of Biological Sciences at Simon Fraser University. The Department has 35 faculty members whose teaching and research interests cover all the modern areas of Biological Sciences. There is a graduate enrolment of some 160 students, and external research grant support in 1988/89 was $2.4 million.

A Departmental Chair appointment is for up to five years and is renewable; the salary is negotiable. The appointment would normally carry tenure. Candidates should have an excellent record in research and a demonstrated ability as an academic leader.

Applications or nominations should be forwarded, by January 15, 1990, to the **Dean of Science, Simon Fraser University, Burnaby, B.C. V5A 1S6.**

This advertisement is directed to people who are eligible for employment in Canada at the time of application. S.F.U. offers equal employment opportunities to qualified applicants. (NW4626)A

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF PHARMACOLOGY

Rhone-Poulenc Post-Doctoral Research Fellowship in Computer-aided Drug Design

Applications are invited for the post of Rhone-Poulenc Research Fellow to pursue research in the field of molecular matching. The project is designed to identify sub-regions of similarity in electrostatic potential on the surfaces of dissimilar molecules and explore this topographical relationship with affinity and biological action. The applicant should have a Ph.D. and experience in computing in a shared mainframe environment. An Evans and Sutherland PS390 graphics computer is available. The project is under the direction of Dr P.M. Dean.

The appointment, which will date from 1st October 1989, will be for 2 years. Salary scale £10,460–14,500. Applications, which should include a C.V. and the names of two referees, should be sent as soon as possible to **Dr P.M. Dean, Department of Pharmacology, University of Cambridge, Tennis Court Road, Cambridge CB2 1QJ.** (2255)A

POSTDOCTORAL POSITION
AT THE DANA-FARBER CANCER INSTITUTE, HARVARD MEDICAL SCHOOL
Molecular Basis of Recognition by T cell Receptor Gamma-Delta

Position available to study molecular basis of antigen recognition by human gamma-delta T cell receptor. Work involves derivation and characterization of antigen-specific gamma-delta T cell clones, cloning, sequencing and transfection of T cell receptor genes, and in vitro site-directed mutagenesis of T cell receptor genes to delineate the residues involved in antigen recognition. Position carries an appointment at Harvard Medical School. Please send curriculum vitae and names of 3 references to **Dr. Hamid Band, Laboratory of Immunochemistry, Mayer 640, Dana-Farber Cancer Institute, 44 Binney Street, Boston, MA 02115, or call at (617) 732-3085.**

An Affirmative Action/Equal Opportunity Employer. (NW4680)A

POST DOCTORAL POSITIONS AVAILABLE IN MOLECULAR ENDOCRINOLOGY

Individuals with strong backgrounds in molecular and/or cellular biology are invited to apply for post doctoral positions in a leading laboratory involved in the investigation of the biosynthetic and regulatory mechanisms in the production of the islet hormones-insulin, amylin, glucagon and others. Areas of concentration include islet prohormone conversion mechanisms, regulation of islet hormone gene expression, expression and role of ion channels in islet cells, insulin receptor signal transduction mechanisms, studies on islet hormone gene evolution and on mutant insulin and insulin receptor genes in human populations.

Wayne State University

FACULTY POSITION IN NMR

The Department of Biochemistry is seeking applicants to fill a tenure-track position. Appointments at any level will be considered. Applicants should have experience in high resolution NMR determination of structure of proteins or other macromolecules, with appropriate graduate and postdoctoral training. Interested individuals should send curriculum vitae, outline of research interests, and the names of three references to: **Barry P. Rosen, Professor and Chairman, Department of Biochemistry, Wayne State University, School of Medicine, 540 East Canfield Avenue, Detroit, MI 48201.**

Wayne State University is an Equal Opportunity/ Affirmative Action Employer. Women and minorities are encouraged to apply. (NW4668)A

ASSISTANT PROFESSOR

Applications are invited for a position at the level of assistant professor (tenure track) in the Department of Chemistry at Stanford University, with primary research and teaching interests in the general area of inorganic chemistry. Applicants must be strongly motivated toward creative research and have a commitment to teaching at the undergraduate and graduate levels. In applying, please send curriculum vitae, list of publications, a brief statement of research interests (three pages or less) and, in addition, have three letters of recommendation sent to **Professor Harden M. McConnell, Chairman, Department of Chemistry, Stanford University, Stanford, California 94305.**

Stanford is committed to Equal Opportunity through Affirmative Action in employment, and we are especially eager to identify minority persons and women with appropriate qualifications. Applications should be received by January 15, 1990. (NW4629)A

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH
LABORATORY OF GENE STRUCTURE AND EXPRESSION

POSTDOCTORAL SCIENTIST

Applications are invited for the post of postdoctoral scientist to work with Dr Elaine Dzierzak in the Laboratory of Gene Structure and Expression (Head: Dr Frank Grosveld). The AIDs-Directed research programme is focussed on intracellular molecular ablation strategies and involves the use of recombinant retroviral vectors. Candidates are expected to have experience in recombinant DNA techniques and mammalian cell culture. A strong background in mammalian gene expression would be favoured.

The position will be tenable for 3 years. The salary will be in the range £12,381 to £20,469 (starting salary dependent on experience) plus £1,650 per annum London Allowance. MRC Pension Scheme option.

Applications including a curriculum vitae, list of publications and the names and addresses of two professional referees should be sent to Mr C R Russell, Administrative Manager, National Institute for Medical Research, The Ridgeway, Mill Hill, London, NW7 1AA, not later than 29th December 1989 quoting reference number GGSE/ADP/PD. Informal enquiries about the nature of the work may be made to Dr Elaine Dzierzak on ext. 2095.

The MRC is an Equal Opportunities Employer. (2247)A

ASSISTANT PROFESSOR

Department of Medicine, Indiana University School of Medicine, with possibility of a joint appointment in microbiology and immunology. Initial research would focus on genetics of virulence factors, including antibiotic resistance, in chlamydiae. A strong background in molecular biology is required. Interested parties reply with a curriculum vitae to: **Robert B. Jones, M.D., Ph.D., Department of Medicine, Room 435 Emerson Hall, 545 Barnhill Dr. Indianapolis, IN 46202-5124.** (NW4682)A

RESEARCH SCIENTIST

($A31,525-$A38,567)

CSIRO DIVISION OF BIOTECHNOLOGY
LABORATORY FOR MOLECULAR BIOLOGY
SYDNEY, AUSTRALIA

THE JOB: The appointee will join a team investigating the interaction of cells with natural extracellular matrix components and with synthetic surfaces. The research aims to use an understanding of extracellular matrix structure and function for the rational design at a molecular level of biomaterials with improved biocompatibility. The duties will include the evaluation of surfaces produced by RF plasma techniques for biocompatibility and blood compatibility, and participation in the design of novel composites of synthetic polymers combined with biological factors for biomaterial applications.

THE PERSON: Applicants should hold a Ph.D. or equivalent qualification in cell biology/biochemistry/anatomy or histology or related discipline. An applicant having experience in one or more of the following areas would be preferred:

- cell biology of tissue structure and function
- control of cell phenotype by trophic factors and extracellular matrix components
- biocompatibility and haemocompatibility of biomaterials
- mechanisms of wound healing responses.

CONDITIONS: Indefinite appointment with Australian Government Superannuation.

MORE INFORMATION: Prospective applicants are invited to contact Dr Jack Steele or Dr Anne Underwood in writing to the address below, by fax to 888 9271 or 61-2-886-4805 or by phone on 61-2-886-4888 for further information. Ms Maree O'Neill may be contacted on these same numbers to provide selection criteria.

APPLICATIONS: Applications quoting reference No. PG1/57 should be submitted by 18th December 1989. Wherever possible they should be framed against the selection criteria and should state relevant personal particulars, including details of qualifications and experience. All applicants should also nominate at least two professional referees. Applications may be faxed to either fax number above or posted to:

The Chief,
CSIRO Division of Biotechnology,
PO Box 184,
North Ryde, NSW 2113,
Australia.

POSTDOCTORAL AND RESEARCH ASSOCIATE POSITIONS

Positions are available in studies of gene expression and regulation in inborn errors of metabolism, including (1) disorders of biotin-dependent carboxylases, (2) lysosomal storage diseases, and (3) development of disease models mediated by homologous recombination. Salaries commensurate with experience. Send curriculum vitae and names of three references to:

Dr. R. Gravel,
McGill University-Montreal Children's Hospital
Research Institute,
2300 Tupper Street,
Montreal, Quebec, Canada, H3H 1P3.

(NW4702)A

ASSISTANT RESEARCH SCIENTIST IN X-RAY CRYSTALLOGRAPHY

The position will involve: equipment development and maintenance, program development, crystal growth and data collection, and structure solutions. Excellent x-ray crystallographic equipment exists and a number of interesting proteins are under study. Applications from scientists with background in small molecular crystallography are welcome. Review of applications will begin January 15, 1990 but applications will be accepted until the position is filled. Salary commensurate with experience. This is a state-funded, continuing eligible position. Candidates are eligible to secure grant funding for their research.

Minority and women candidates are urged to apply.

Submit a CV and three letters of reference to: **Dr. William Montfort, Dept of Biochemistry, Biosciences West, University of Arizona, Tucson, AZ 85721.**

An Equal Opportunity/Affirmative Action/Title IX/Section 504 Employer. (NW4676)A

The University of Bayreuth announces three tenured positions in the newly formed Bayreuth Institute of Terrestrial Ecosystem Research (BITÖK):

PROFESSOR OF ECOSYSTEM PLANT ECOLOGY
PROFESSOR OF SOIL MICROBIOLOGY
PROFESSOR OF SOIL SCIENCES

BITÖK was formed in 1989 with the aim to study the processes governing ecosystem structure and function. Specifically, the program's main emphasis is to understand and quantify temporal and spatial variations in the supply and demand of carbon and nutrients in ecosystems. The research in BITÖK is cooperative with that of the faculty of Biology, Chemistry and Geosciences at the University of Bayreuth. The institute is funded by a grant from the German Federal Minister of Science and Technology (BMFT). At its completion, BITÖK will contain departments of ecosystem plant ecology, soil science/soil physics, soil microbiology, hydrogeology, zoology, climatology and ecological modelling. In addition to these departments the institute will contain a technical group which will provide support including computer expertise, electronical and mechanical workshops and analytical chemistry.

Description of position: This is a newly established full-time, 12 months, faculty appointment with tenure and professional responsibilities at BITÖK. Individual professors in BITÖK are expected to cooperate in an integrated research program in the context of terrestrial ecosystems.

Qualifications: Applicants must have a Ph.D. degree in the respective field. Applicants who have not completed their habilitation (German system) or are not yet tenured would be required to demonstrate an outstanding research and teaching experience in the field. A great weight in hiring will be given to an ability for interdisciplinary research. In the initial phase of BITÖK the position responsibilities include establishing, in cooperation with other departments, scientific programs and the necessary laboratory capacities. The responsibility also includes teaching. The University of Bayreuth is an equal opportunity employer.

Salary will be competitive and paid according to the C4 level (a German equivalent of a full professor in the American system).

Support: The research program is supported by BITÖK with research assistants, technicians and a research budget.

Applications must include a letter of research perspectives, a curriculum vitae (including a complete list of publications, and an up-to-date short description of research and teaching experience), and reprints of important publications. The applications should be addressed to:

Dean of the Faculty of Biology, Chemistry and Geosciences,
University of Bayreuth,
POB 10 12 51,
8580 Bayreuth,
Federal Republic of Germany

Official closing date for applications is January 25, 1990.

Information: contact the Bayreuth Institute of Terrestrial Ecosystem Research,
Scientific Secretary, POB 10 12 51 D-8580 Bayreuth, FRG
(University of Bayreuth — FAX: FRG – 921 – 6 48 89)

INSTITUTE FOR
ANIMAL HEALTH

VIROLOGIST — MOLECULAR BIOLOGIST — BIOCHEMIST

Postdoctoral position (2–3 yr) available at the Pirbright Laboratory to work with a group engaged in basic research on the genetics and molecular biology of FOOT-AND-MOUTH DISEASE VIRUS (FMDV). Ours is an active, rapidly expanding group, which benefits from strong collaborative links with Universities. The group forms part of the DIVISION OF MOLECULAR BIOLOGY, which comprises some 30 scientists, PhD students and assistants.

The project is to engineer new antigenic sites into FMDV, a small RNA virus whose crystal structure was recently solved. The successful candidate will be seeking a challenging research project in the area of protein engineering/chimaeric viruses. He/she will have a PhD and experience in some area of molecular biology or a related discipline.

PIRBRIGHT LABORATORY, located near Guildford and Woking, is the UK centre for the study of exotic viruses of domestic animals, and is home to the World, and European, Reference Laboratories for FMDV.

Salary between £10,678 and £18,864 according to age and experience, plus non-contributory pension scheme. HOUSING available.

ENQUIRIES to Dr Andrew King (0483232441). To apply, please forward CV and names of two referees to **The Pirbright Laboratory, IAH, Ash Road, Pirbright, Woking GU24 0NF.**

Closing date: 22nd December 1989.

The AFRC is an equal opportunities employer. (2294)E

IMMUNEX RESEARCH AND DEVELOPMENT CORPORATION, a Seattle-based biopharmaceutical company committed to research and development for treating diseases related to malfunctions in the immune system, is currently recruiting for:

Staff Scientists and Postdoctoral Fellows

With experience in the following areas:

Process Development/ Biochemical Engineering

Successful candidates will work on purification, scale-up, and refolding of recombinant proteins expressed in microbial and mammalian cell hosts. Additional positions are available for work on protein characterization and formulation. A background in biochemical engineering, biochemistry or protein chemistry is preferred.

Experimental Hematology

Staff Scientist needed to contribute to experimental hematology program. Researcher needed for development of in vitro and in vivo models of hematopoiesis. Particular emphasis will be placed on the establishment of assays having the capacity to detect novel hematopoietic growth factors.

Immunology

Scientific researcher needed with expertise in culturing of monocytes/macrophages and assessment of their activation. Expertise in dealing with human cells a plus; experience with cytokines desired.

Immunex Research and Development Corporation offers excellent opportunities for career development as well as competitive salaries and an excellent benefits package. For consideration, please submit C.V., names of three references, and list of publications to: **Immunex Research and Development Corporation, Human Resources Director, 51 University Street, Seattle, WA 98101.** EOE.

Technische Universität Braunschweig

An der *Naturwissenschaftlichen Fakultät* ist im Rahmen eines gezielten Ausbaus der Biowissenschaften sofort folgende Stelle erstmals zu besetzen:

eine Professur (C4) für Zellbiologie/Molekularbiologie

Von dem künftigen Stelleninhaber wird erwartet, dass er den im Aufbau befindlichen Forschungsschwerpunkt Biotechnologie durch seine Forschung prägend mitbestimmt und aktiv an dem neu eingerichteten grundständigen Studiengang Biotechnologie und dem Schwerpunktstudium Bioverfahrenstechnik mitwirkt. Der Stelleninhaber wird über eine solide personelle und sächliche Grundausstattung verfügen und hervorragende Arbeitsmöglichkeiten im Biozentrum vorfinden. Durch die enge Zusammenarbeit auf dem Gebiet der Biotechnologie zwischen der Technischen Universität und der Grossforschungseinrichtung GBF (Gesellschaft für Biotechnologische Forschung mbH) bestehen darüber hinaus attraktive Möglichkeiten für Kooperationen.

Die allgemeinen Einstellungsvoraussetzungen für Professoren sind in §56 des Niedersächsischen Hochschulgesetzes geregelt, dessen Text auf Anforderung zugesandt wird.

Bewerbungen sind innerhalb von 8 Wochen nach Erscheinen dieser Anzeige an den **Vorsitzenden der Naturwissenschaftlichen Fakultät der TU Braunschweig, Professor Dr. H. Brass, Pockelsstrasse 14, D-3300 Braunschweig,** zu richten, der auf Anfrage auch über weitere Einzelheiten Auskunft gibt. (W6807)A

PLANT BIOLOGY RESEARCH FELLOWSHIPS

SAMUEL ROBERTS NOBLE FOUNDATION and THE SALK INSTITUTE JOINT PROGRAM

Applications are now being accepted for two Noble Foundation Fellowships for post-doctoral research in Plant Molecular Biology. These Fellowships are a key element in a collaborative program between the Plant Biology Division, Noble Foundation, Ardmore, Oklahoma, directed by Dr. Richard A. Dixon, and the Plant Biology Laboratory, The Salk Institute for Biological Studies, La Jolla, California, directed by Dr. Christopher J. Lamb.

Research topics include biochemical, molecular and genetic analysis of signal transduction pathways for environmental and developmental regulations of plant gene expression. The Fellowships are for three years beginning September 1990. Eighteen months will be spent in each laboratory.

Please send resume and three letters of recommendation to Dr. C.J. Lamb, The Salk Institute for Biological Studies, P.O. Box 85800, San Diego, CA 92138. Telephone (619) 453-4100, x106.

Equal Opportunity Employer M/F/H/V (NW4710)A

SENSORY SCIENTIST

Research Scientist — Senior Research Scientist

$A31,525-$A45,699

SENSORY RESEARCH CENTRE
CSIRO DIVISION OF FOOD PROCESSING
SYDNEY, AUSTRALIA

The CSIRO Division of Food Processing has maintained a strong interest in sensory research for 20 years and its achievements have earned it a world wide reputation for excellence in gustation and olfaction. In 1987 the Division established the Sensory Research Centre to consolidate its sensory research, assist the Australian food industry to improve product quality and to become a centre of expertise on Asian food preferences. The Centre has established a successful sensory evaluation research service for the food industry and has recently received substantial funds for a major study of sensory responses of Asian populations. The Centre is currently planning a study located in Japan. Within the next two years it is expected that the Centre will move into a new building at the Sydney site, the function of which is to support its Australian and Asian projects. The Division of Food Processing is committed to assisting development of Australian food exports through its excellence in scientific activity.

THE JOB: Conduct fundamental studies on the sense of taste with the objective of understanding the underlying factors which determine food acceptance. The studies could embrace research on psychophysical measurement techniques, complex taste stimuli; integration of odour-taste responses, psychophysiological approaches, and the effects of age, experience, culture and disease on taste and food acceptance. The successful applicant will be expected to participate in the other activities of the Sensory Research Centre which will involve sharing responsibility with the two Principals of the Centre for the supervision of short term sensory evaluation contract research with the food industry and studies of cross cultural food preferences of Asian populations. In view of the blend of long and short term research work this challenging position will entail, a creative, entrepreneurial scientist is sought. A higher salary can be negotiated for an outstanding candidate.

THE PERSON: Applications are invited from scientists with a record of research in sensory perception. A highly motivated person is sought who is interested in establishing a reputation for excellence in the field of taste research and in applying new knowledge to practical areas of sensory perception.

QUALIFICATIONS: A Ph.D or equivalent in the behavioural or physiological sciences or related scientific discipline with experience in sensory perception.

TENURE: Appointment will be for an indefinite period with Australian Government superannuation benefits.

THE DIVISION: The Food Research Laboratory, Division of Food Processing, is situated at North Ryde, some 12km from the city of Sydney. Its research programmes reflect the Division's objectives which are to develop ways to handle, process and add value to foods, to improve efficiency, quality and food safety and to minimize or utilize waste. Areas of activity at the Laboratory include sensory studies, separation processes, process engineering, preservation technology, microbial physiology, food spoilage, and food pathogens. An Industry Initiatives Group deals with liaison, communications and general publications.

MORE INFORMATION: Prospective applicants are invited to write or phone Dr David Laing or Dr Graham Bell on 61 02 887 8333 or by fax on 61 02 887 3107 for further information. Copies of the detailed job description and selection criteria are available on request.

APPLICATIONS: Applications should be submitted by 22 January 1990 and should quote the reference number (FD89/14). They should be framed against the selection critieria and should provide details of relevant personal particulars including qualifications and experience. Applicants should nominate at least two professional referees and address their applications to:

The Chief,
CSIRO Division of
Food Processing
PO Box 52,
North Ryde, NSW 2113,
Australia.

or they may be faxed to 61 02 887 3107.

CSIRO AUSTRALIA

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W6808)A

LUDWIG INSTITUTE FOR CANCER RESEARCH

St Mary's Branch

A postdoctoral position will become available in the Epstein-Barr virus group from February 1990. The post might particularly interest candidates with an interest in the biology of B cell growth control, control of gene expression in response to cell differentiation or genetic approaches to analysing viral functions. The Institute offers excellent working conditions in newly refurbished laboratories in central London.

Applications including CV and the names of three referees should be sent to **Dr. P.J. Farrell, Ludwig Institute for Cancer Research, St Mary's Hospital Medical School, Norfolk Place, Paddington, London W2 1PG.** Tel: 01-724 5522. (2193)A

Wellcome Diagnostics

Post Doctorates

Vacancies in Virology

£15,000 - £23,000 **Beckenham, Kent**

Wellcome Diagnostics develops, manufactures and markets a wide range of medical diagnostic kits for use in hospital laboratories and blood banks. Rapid expansion demands that we look for Post Doctoral Scientists to work in this important area of research.

Allowing you the freedom to approach problems in a creative and innovative way will enable you to complete research projects using expert scientific knowledge and the latest technology within a well funded environment.

We are looking for 2 scientists in the following area:

As a committed Enzyme Immunoassayist you will apply your experience in the fields of retroviruses, hepatitis and other virally transmitted diseases to invent and develop immunoassays.

A knowledge of the safe handling of pathogens is essential; you must have experience in micro-titre plate based assays and be prepared to work to ensure the complete development of assays through to Production.

The other post requires new and creative ideas in the field of immunoassays with a view to making novel formats commercially viable over the next couple of years. You will also provide protein chemical support for the current generation of immunoassays.

Self motivated and highly creative, you will probably be a chemically orientated biochemist or immunologist with some experience of peptide and recombinant protein chemistry. Your experience may have included enzyme modification or engineering but will definitely have included protein chemistry and possibly nucleic acid chemistry.

Scientific collaboration and publication of your work in respected journals will enable you to promote awareness of Wellcome Diagnostics.

Experience, maturity and the ability to make a valid contribution to research will be reflected by a highly competitive salary. In addition, you can look forward to a comprehensive range of benefits including 5 weeks holiday, pension and life assurance schemes, a subsidised restaurant and first-class sports and social facilities.

Please write with full career details, quoting reference number 91/182 to Susan Lark, Personnel Assistant, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent, BR3 3BS.

- **The Wellcome Foundation Ltd.**
- **Major International Pharmaceutical Group**
- **Research Centre at Beckenham**
- **Annual Turnover > £1,400m**
- **An Equal Opportunity Employer**

Wellcome

(2289)A

The Imperial Cancer Research Fund is one of the largest charity research institutions in Britain with wide ranging interests in fundamental, applied and clinical research.

Research Fellowship

A post-doctoral fellowship is available to work on novel gene organization and regulation in mammalian cells. The molecular mechanisms and cis and trans acting sequences involved in the control of gene expression and gene amplification will be investigated. Candidates should have experience in molecular biology and recombinant DNA technology. The award will be tenable for up to three years with a salary of **£14,800-£18,500** depending on experience.

For further details contact Dr. Mike Fried on 01-269 3297. Please send full curriculum vitae and names and addresses of three referees to the address below, quoting reference 34/R.

Scientific Officer/ Senior Scientific Officer

We require an SO/SSO to work with Dr P. Goodfellow in the Department of Human Molecular Genetics. The work involves the in vitro production and biochemical purification of proteins produced by genes located on the human Y chromosomes.

Degree or equivalent is required in a relevant subject (SO) with a minimum of 6 years working in a research laboratory (SSO). Experience in biochemical techniques and ability to work independently are both essential. Some experience in immunogenetics and molecular genetic techniques would be an advantage, but, is not essential. Ref: 41/R.

£11,200-£17,800

Scientific Officer/ Senior Scientific Officer

We are also looking for an SO/SSO to work at our Biochemical Regulatory Mechanisms department in WC2.

You will assist in analysing the second message (signal transduction) pathways and factors involved in the control of interferon-inducible gene expression and mechanisms by which the interferons inhabit virus replications and cell growth.

Degree or equivalent is required in a relevant subject (SO) with a minimum of 6 years working in a research laboratory (SSO). Experience in molecular biology, biochemistry and tissue culture would be advantageous. Ref: 42/R.

£11,200-£17,800

Institute of Hydrology

GROUNDWATER HYDROLOGIST

Wallingford, Oxon

We are seeking one or more ground water hydrologists to join the Consulting Group of the Institute. This group undertakes applied projects for clients in the UK and overseas.

The post(s) will offer the opportunity to be involved in a range of research and applied studies in the field of water resources and environmental protection, mainly involving unconsolidated alluvial aquifers. Much of the work will be computer based and some competence with PC's and knowledge of the FORTRAN language would be an advantage. At least one candidate should be familiar with groundwater modelling techniques, which are an essential input to the majority of studies undertaken.

Applicants require a good honours degree in geology or related subject, and preferably a postgraduate qualification in hydrogeology. Some experience overseas would be an advantage but is not essential.

The appointment(s) will be for three years in the first instance. Salary will be in the range of **£10,678** to **£14,909** per annum, or **£13,254** to **£18,864** per annum, depending on qualifications and experience. Terms include a generous holiday allowance and non-contributory pension scheme.

The Institute of Hydrology is a component organisation of NERC.

Further information and application forms may be obtained from Sue Fenton, Institute of Hydrology, Wallingford, Oxon, OX10 8BB. Telephone 0491-38800. Closing date for applications is 28th December 1989.

Previous applicants need not apply.

The Natural Environment Research Council is an Equal Opportunities Employer.

UNIVERSITY OF OXFORD

University Lectureship in Astrophysics in association with St. Catherine's College

Applications are invited for a University Lectureship in Astrophysics. The successful candidate will be offered a tutorial fellowship at St. Catherine's College. Some preference will be given to applicant's with research interests in extragalactic observational astronomy, but candidates from all branches of astrophysics are encouraged to apply.

Further particulars of the lectureship and of the college fellowship may be obtained from **Prof. G.P. Efstathiou, Department of Astrophysics, Keble Road, Oxford, OX1 3RH,** to whom a curriculum vitae should be submitted by 31st January 1990. Applcants should arrange for letters from three referees to reach the Department by the closing date.

(2293)A

The University is an Equal Opportunity Employer

PEPTIDE TECHNOLOGY LTD/CSIRO

(Molecular Biologist/Protein Chemist)

Oxidative radicals in sunlight induced damage and oncogenesis in skin.

Peptide Technology Ltd. is a Sydney-based biotechnology company with research and production facilities in Copenhagen (Carlbiotech A/S) and in Sydney. In association with collaborating institutions both in Australia and in Europe it is developing novel therapeutic products for use both in human health-care and in animal production. Current R & D programmes include the development of treatments for inflammatory conditions, cancer and certain immunological disorders, as well as enhancement of growth and fertility modification in the veterinary product area.

The Company requires an energetic and self-motivated scientist to study the significance of and prevention of free radical damage in skin cancer and aging in a joint project with CSIRO. The successful applicant will have a background in DNA or protein chemistry; molecular or cell biology.

The successful applicant will work in the Company's Biomedical Research laboratories at the Laboratory for Molecular Biology of the CSiRO Division of Biotechnology, N. Ryde, Sydney in association with a number of other scientists working in similar or complementary fields including Drs. R. Holliday FRS, G.Grigg, R. Aston, H. Drew and A. Underwood.

Starting salary will be between AUS $31,500 — $38,500 depending on qualification and experience. Other benefits include a generous superannuation scheme and share options.

Please write with full C.V. to the **Operations Manager, Peptide Technology Ltd., PO Box 444, Dee Why, NSW, 2099 Australia,** or Fax to 61 2 805 1630.

FACULTY POSITION IN NEUROBIOLOGY

EUROBIOLOGY RESEARCH CENTER
UNIVERSITY OF ALABAMA AT BIRMINGHAM

e to continued expansion of the NRC in the B School of Medicine, a new tenure track sition in **MOLECULAR NEUROBIOLOGY** is ailable. The appointment will be at the **SISTANT** OR **ASSOCIATE PROFESSOR** level, mmensurate with experience. The successful ndidate will be expected to conduct an active, tramurally funded research program related to pects of synaptic function including normal nsmission, plasticity or development. Particu- consideration will be given to individuals ing contemporary tools that afford insight into NE EXPRESSION AND REGULATION. The ap- intment is on a 12 month basis and includes tionally competitive salary, newly revovated ace and start-up funds. The NRC is currently mposed of 16 faculty members with actively nded research programs in synaptic and mem- ane biophysics, molecular bioloigy of synaptic ansmission, neuroendocrinology, peptide odulation of neural rhythmicity, neuroem- yology and neuron/glia interaction in develop- ent and regeneration. Access to shared facili- es including a premiere neuronal image analy- s center and super computer network are avail- le in the NRC. UAB is a major biomedical re- arch center with thriving graduate programs in urobiology, Immunology and Molecular Biol- gy and is located in an economically favorable d culturally vibrant community. Applicants ould send curriculum vitae, statement of re- earch interests and have three letters of refer- nce sent by January 28th to: **Micheal J. Fried- nder, Director, Neurobiology Research Center, niversity of Alabama at Birmingham, Birming- am, Alabama, 35294.** *UAB is an affirmative ction/equal opportunity employer.* (NW4678)A

NA Library Availability

National Laboratory Gene Library Project

he Department of Energy National Labora- ries at Los Alamos and Livermore are currently onstructing large-insert lambda and cosmid varies for each human chromosome. The two boratories are seeking proposals from in- estigators who are interested in participating in ne characterization of these libraries on a col- borative and unfunded basis. Many types of haracterization data are needed, and the incor- oration of library usage into ongoing research vill provide useful information.

his is a competitive program; only a small umber of the best proposals will receive either hage and/or cosmid libraries at no cost. Distribution worldwide will take place only after his characterization phase has been suc- essfully accomplished. Partial digest libraries n both phage and cosmid vectors are available urrently (or early 1990) for chromosome 4, 5, 8 and 17 (from Los Alamos) and chromosomes 11, 21, 22, and Y (from Livermore). The deadline for ubmission of a short proposal is Monday, January 29, 1990.

Vrite to the appropriate laboratory, Larry L. Deaven, Life Sciences Division, Los Alamos Na- ional Laboratory, Los Alamos, NM 87545, fax: 505) 665-3024, or Marvin A. Van Dilla, Biomedical Sciences Division, Lawrence Liver- more National Laboratory, Livermore, CA 94551, ax: (415) 423-3608, for proposal forms.

Research Professionals in Biotechnology

ImmunoGen is a rapidly growing biotechnology company dedicated to the development of immunotoxins and other cancer therapeutics. We are seeking talented scientists to join us in exploring new approaches to human disease. Research positions are available at Ph.D., M.S. and B.S. levels in our expanding research programs. Candidates should enjoy taking the initiative in solving scientific problems to achieve near-term and long-term goals.

STAFF SCIENTISTS IN BIOCHEMISTRY

Candidates should have a Ph.D. in Biochemistry or related disciplines, with a strong research background in biochemistry. People with a proven record of realizing ideas through developing independent research projects, such as group leaders or junior faculty, would be strong candidates.

STAFF SCIENTISTS IN CELL BIOLOGY

Candidates should hold a Ph.D. in cell biology, immunology or related disciplines and have a strong research background and publication record in mammalian cell biology.

STAFF SCIENTIST IN MOLECULAR BIOLOGY

Our newly established molecular biology laboratory is developing a research program to include among other projects cloning, characterization and expression of cell surface antigens, construction, mutagenesis and expression of chimeric proteins. Qualified candidates should possess a Ph.D. in molecular biology and have a strong background in molecular cloning methods, cDNA library construction and screening, and DNA sequencing.

RESEARCH ASSOCIATES

A number of opportunities exist for associate scientists at the B.S. and M.S. level in cell biology, molecular biology, biochemistry and organic chemistry. Research areas include characterization and study of human cell lines, *in vitro* evaluation of immunotherapies for cancer and other diseases, DNA cloning and sequencing, drug synthesis and immunoconjugate construction.

ImmunoGen offers an excellent salary and benefits package including 100% paid Health and Dental Insurance and Tuition Assistance. The company is located in a new, fully equipped, state-of-the-art laboratory in Cambridge, midway between the campuses of HARVARD and MIT.

Please send a detailed resume including three references and a statement describing your scientific interests and career goals. All responses will be acknowledged. Reply to: ***Jeanne Horgan, Personnel Department, ImmunoGen, Inc., 148 Sidney Street, Cambridge, MA 02139.***

IMMUNOGEN, INC.

(NW4684)A

An Equal Opportunity Employer

INSTITUTE OF CHILD HEALTH
University of London
Leukaemia Research Fund Centre for Childhood Leukaemia
Department of Haematology and Oncology

CYTOGENETICIST

Applications are invited from candidates with experience in human cytogenetics for the above post in this expanding department. The person appointed will be required to assist in the processing and cytogenetic analysis of bone marrow and peripheral blood samples from children with leukaemia and other haematological disorders and to participate in research projects.

Salary on Probationary Biochemist scale £9,815-£12,340, including London allowance.

Informal enquiries to Dr. B.R. Reeves, 242 9789 ext. 2314, or Prof. J.M. Chessels, ext. 2318.

Further particulars are available from the **Personnel Assistant, 30 Guilford Street, London WC1N 1EH (tel: 01-242 9789 ext 2650)** to whom completed applications (3 copies) and names of two referees, should be sent as soon as possible. (2256)A

UNIVERSITY OF WALES COLLEGE OF MEDICINE
DEPARTMENT OF SURGERY

RESEARCH OFFICER required to work on an MRC-funded project to establish the identity of neutrophil-derived metabolites of 5 amino-salicylate in order to provide indicators of the progress of inflammatory disease. Candidates should have a first degree in a biochemical or chemical discipline. The project, which is a pilot study, is funded initially for one year but suitably qualified candidates may enrol for a higher degree.

Starting salary up to £10,458 per annum.

Further particulars (quoting Ref. No. S19/2/91) are available from the **Personnel Office, University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XN** (Tel. No. 0222/755944 Ext. 2296) and more detailed information from Dr. M. D. Hallett (Ext. 2748/3). Application in the form of a curriculum vitae with the names and addresses of two referees to the Personnel Officer by January 5th. (2248)A

UNIVERSITY OF ABERDEEN
DEPARTMENT OF GEOLOGY AND PETROLEUM GEOLOGY
OCCIDENTAL POSTDOCTORAL RESEARCH FELLOW IN PETROLEUM GEOLOGY

The appointee will work in collaboration with Dr N H Trewin of the University and the geological team at Occidental Petroleum (Caledonia) Ltd in Aberdeen. The research project is a study of the mineralogy and derivation of late Jurassic and early Cretaceous reservoir sandstones of the Witch Ground Graben, N Sea. Postgraduate experience in sedimentary petrology, sedimentology, diagenesis and log interpretation is preferred. Publication of results is expected. The appointment will be for one year and the salary will be within the range £10,458–£14,703. Candidates should be available to start in March 1990.

Applications by letter with CV and names of 2 referees to the **Personnel Office, University of Aberdeen, Regent Walk, Aberdeen AB9 1FX** by 31 January 1990 quoting reference number JA/079.. (2254)A

QUEEN MARY AND WESTFIELD COLLEGE
(University of London)
School of Mathematical Science (Astronomy Unit)
Research Position in Astronomy

Applications are invited for a Post Doctoral position in Professor Rowan Robinson's IRAS group, currently working on cosmology, starburst and active galaxies, background radiation and star formulation. The post is for an observational astronomer to carry out ground-based follow-up of the IRAS and ROSAT missions. Programming experience and a background in astronomy are essential. Salary will be in the range of £12,738 – £15,177, depending on age and experience. The position is funded by SERC for two years in the first instance, to start as soon as possible.

Please apply to **Personnel Office, Queen Mary and Westfield College, Mile End Road, London E1 4NS.** Applications by CV which should include a publication list, summary of research experience and the names and addresses of two referees. Applications should arrive no later than 2nd January 1990) and quote reference no 89/221. (2274)A

THE AUSTRALIAN NATIONAL UNIVERSITY
Research School of Biological Sciences
MOLECULAR NEUROBIOLOGY GROUP
POSTDOCTORAL FELLOW/ RESEARCH FELLOW

A postdoctoral position is available to study mechanisms of motoneuron pathfinding in insects. The work initially will be on grasshopper, with possible extension to Drosophila. Either a cellular approach, involving ablation or blocking of putative guidance cues followed by embryo culture, or a molecular approach, based on cloning the insect homologues of putative vertebrate guidance molecules, may be pursued depending on the background of the successful applicant. Position available from about May, 1990, for up to three years. An appropriate PhD is required, with three years postdoctoral research experience being desirable for appointment at the Research Fellow level. Enquiries to Dr Eldon Ball, Molecular Neurobiology Group, RSBS, PO Box 475, Canberra City, ACT 2601, Australia. Phone 61-62-49-4496, FAX 61-62-48-9995 or 61-62-49-0758.

Closing date: 15 February 1990. Ref: BS 16.11.1

Salary: Research Fellow: A$32,197-41,841 p.a.; Postdoctoral Fellow Grade 1 (fixed point): A$27,953-31,808 p.a. Applications should be submitted in duplicate to the Registrar, The Australian National University, GPO Box 4, Canberra ACT 2601, Australia, quoting reference number and including curriculum vitae, list of publications and names of at least three referees. The University reserves the right not to make an appointment or to appoint by invitation at any time. Further information is available from the Registrar, or from Appointments (37255), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

The University is an equal opportunity employer (W6787)A

POSTDOCTORAL POSITION

available now to study myeloid membrane structure/function. Projects involve granulocyte membrane protein purification and characterization of molecules recognized by myeloid-specific monoclonal antibodies. Send CV and three names or letters of reference to: **Dr. Keith Skubitz, Department of Medicine, Box 325 UMHC, University of Minnesota Medical School, Minneapolis, Minnesota 55455.** Equal Opportunity Employer.

UNIVERSITY OF LONDON

INSTITUTE OF PSYCHIATRY

Lectureship in Molecular Cytogenetics

Applications are invited for a post of Lecturer in Molecular Cytogenetics. The successful candidate will be expected to develop research and teaching and to provide a clinical cytogenetics service to the Bethlem and Maudsley Hospitals. Applications are invited from individuals with experience in cytogenetics and/or molecular genetics. Opportunities for training will be provided in Areas in which the candidate is inexperienced, and it is anticipated that part of the lecturer's time will initially be spent at the Genetics Unit at Guy's Hospital.

Salary on the non-clinical lecturer scale.

Applications in the form of a curriculum vitae with the names and addresses of two referees should be submitted to the **Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF,** from whom further particulars may be obtained. Closing date 12 January, 1990. (2272)A

LINUS PAULING INSTITUTE OF SCIENCE AND MEDICINE

POSTDOCTORAL POSITION IN CHROMATIN

Applications are invited for the above position, available immediately, to study the role of poly(ADP-ribosylation) in chromatin structure, repair and replication. Experience with recombinant DNA techniques, as well as Southern blotting, would be an advantage.

Salary: $25,000 per annum plus fringe benefits and travel expenses.

The Linus Pauling Institute is located in Palo Alto, near Stanford University. Please send your curriculum vitae, publications list and two letters of recommendation to:

Teni Boulikas, Ph.D.,
Head, Laboratory of Molecular Carcinogenesis
Linus Pauling Institute
440 Page Mill Road, Palo Alto, CA 94306

(NW4703)A

POSTDOCTORAL/ RESEARCH ASSOCIATE

Available immediately. Research on species- and tissue-specific enzyme compartmentation. General biochemical background required, experience with protein and rDNA technologies preferred. Salary competitive.

Contact **Dr. James W. Campbell, Dept. Biochem. Cell Biol., Rice Univ., P.O. Box 1892, Houston TX 77251.**

An Equal Opportunity/Affirmative Action Employer. (NW4704)A

UNIVERSITY OF WALES COLLEGE OF MEDICINE

DEPARTMENT OF MEDICINE

INSTITUTE OF NEPHROLOGY (INCORPORATING THE K.R.U.F. INSTITUTE)

RESEARCH OFFICER required from 1 January 1990 for a period of two years. The successful applicant will work on a project to continue current research into the role of lipids in renal disease using glomerular cell culture techniques already established in the Department. Experience in lipid biochemistry would also be helpful.

Salary will be on the scale for University Research and Analogous Staff Grade 1A (£10,458-£16,665 p.a.) starting point dependent on age and experience, up to £12,381 per annum.

Further particulars available from the **Personnel Office, University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XN (Tel. 0222/ 755944 Ext. 2296)** to whom applications in the form of a curriculum vitae with the names and addresses of three referees should be submitted within 3 weeks of the appearance of this advertisement.

UNIVERSITY OF NEWCASTLE UPON TYNE

CLINICAL SENIOR LECTURESHIP AND CLINICAL LECTURESHIP IN THE DEPARTMENT OF CLINICAL BIOCHEMISTRY AND METABOLIC MEDICINE

As part of an expansion and further commitment to research activities applications are invited for two new academic appointments in the Department of Clinical Biochemistry and Metabolic Medicine.

CLINICAL SENIOR LECTURER IN CLINICAL BIOCHEMISTRY

The successful candidate will have proven abilities in research and will want to develop these further. It is expected that he or she will have a higher degree. While suitable applicants in all areas will be considered seriously, those with a background in molecular endocrinology and/or immunology would be particularly welcome. Duties will include teaching at undergraduate and postgraduate levels and participation in the clinical and administrative activities of the Department.

CLINICAL LECTURER IN CLINICAL BIOCHEMISTRY

The successful candidate will want to follow a career in clinical research. Applicants who wish to interact productively with a new Immunology Group being formed in the area of immunogenicity would be particularly welcome. Duties will include teaching at undergraduate and postgraduate levels and participation in the clinical and administrative activities of the Department.

The first appointment will be made at a suitable point on the Clinical Senior Lecturer's salary scale (£29,700-£38,340 p.a. if Honorary Consultant contract held and £23,570-£33,260 p.a. without Honorary Consultant contract). The second appointment will be made at a suitable point on the Clinical Lecturer's salary scale (£14,545-£25,500 p.a.).

Further particulars may be obtained from the **Senior Assistant Registrar (Establishments), The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU** with whom applications (three copies) together with the names and addresses of three referees should be lodged by the 2nd January 1990. (2277)A

RESEARCH ASSOCIATE OR POST-DOCTORAL FELLOW

Biochemist/Biologist wanted to investigate the molecular genetics of signal transduction in eukaryotes. Project involves identification and characterization of genes whose products are important in cell surface receptor mediated gene induction. Salary: $25,000-$32,000 commensurate with experience and qualifications. Send CV to: **Dr. Robert P. Dottin, Hunter College, CUNY, Center for Study of Gene Structure and Function, 695 Park Avenue, New York, NY 10021.**

FELLOWSHIPS

The Royal Society

RESEARCH FELLOWSHIPS VACANT
from 1 October 1990

The following 40 appointments have recently been advertised to be taken up on 1 October 1990, viz:

University Research Fellowships (28) in any scientific subject for candidates preferably between 26 and 33

Research Fellowships (4) in the medical, biological and chemical sciences for candidates preferably between 33 and 40

The Royal Society-BOC Limited Research Fellowship (1) for a subject of research in a field of direct interest to BOC for applicants preferably under 33

Rutherford Scholarships (2) for candidates under 26 to do a Ph.D in a part of the Commonwealth different from that in which the candidate graduated

Royal Society Leverhulme Trust Senior Research Fellowships (5) for candidates between 35 and 55 with substantive posts in British universities to do full-time research for one year

Details of all the vacancies appeared in **Nature** on 16 November 1989, (classified, p.17), giving information on eligibility and conditions, including permitted nationality of applicants and places of tenure of the appointments.

Apply by letter for application forms and further details (**stating for which appointment**):
Mrs U. M. A. Tokle, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG.

(2264)E

Closing Date: 16 February 1990
No application forms will be issued after 2 February 1990 and no applications arriving after 4 p.m . on 16 February will be considered.

APPTS. VACANT
continued

UNIVERSITY OF BRISTOL

SCHOOL OF CHEMISTRY

LECTURESHIP IN BIO-ORGANIC CHEMISTRY

Applicants are invited under the New Academic Appointments Scheme which is intended to create career opportunities for younger academic staff. Salary will be assessed on the Grade A scale (£10,458–£15,372).

Applications, in the form of a detailed curriculum vitae with an explanatory letter giving names and telephone numbers of three referees, should be sent to **the Registrar, Senate House, Bristol, BS8, 1TH, from whom further details may be obtained. Please quote reference CYF 3.**

Closing date 31 January 1990.

An equal opportunities employer. (2282)A

FOULKES FOUNDATION FELLOWSHIPS 1990

The Foulkes Foundation provides financial support for recently qualified science graduates with research experience who want to study medicine, and for medical graduates who want to take a science degree. In both cases graduates must intend to do medical research after qualification.

Application forms and further information available from the Registrar, Foulkes Foundation Fellowship, 37 Ringwood Avenue, London N2 9NT, enclosing S.A.E.

Closing date — 15th March, 1990. (2278)E

Harvard University

announces Bullard Fellowships in Forest Resources with stipends available for advanced study and research. Fellowships are open to individuals in academic careers, public service, or private forestry with stipends up to $25,000. Further information may be obtained from: **Committee on the Charles Bullard Fund for Forest Research, Harvard University, Harvard Forest, Petersham, Massachusetts 01366.** Deadline for applications: February 1, 1990. (NW4697)E

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1990 AWARDS

Next deadline: 15th February 1990

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are usually awarded initially for one year, but with the possibility of renewal for a second year. In cases of exceptional scientific merit, however, the selection committee can award a 2-year fellowship. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 February 1990. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 23 April 1990.

Application forms and further details may be obtained from **Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.** Inquiries should be accompanied by a self-addressed adhesive label. (W6801)E

THE ARTHRITIS & RHEUMATISM COUNCIL

ARC

ARTHRITIS & RHEUMATISM COUNCIL FOR RESEARCH

SENIOR A R C FELLOWSHIPS

The purpose of these fellowships is to provide support for outstanding medical or basic science graduates committed to a research career in any aspect of the rheumatic diseases. Candidates should have proven research ability in a relevant discipline.

These fellowships will normally be for 5 years, with possible renewal, subject to satisfactory review. They are tenable in universities and research institutions in the UK only.

Salary would be according to age and experience on appropriate salary scales. Funds would also be available for a technician, laboratory expenses and essential equipment not normally provided for by departmental funds.

Applications should include evidence of appropriate support and facilities from the host department.

Application forms and further information are available from the

Research & Education Secretary,
The Arthritis & Rheumatism Council,
41 Eagle Street,
London WC1R 4AR.

Completed applications should be received by Thursday, 1 March 1990. (2276)E

LUCILLE P. MARKEY VISITING FELLOWSHIPS

Nominations are invited for postdoctoral fellowships under the above programme. Four awards will be made to outstanding candidates wishing to further their careers in biomedical science at an institution in the U.S.A. Candidates *must* be nominated by an institution in the U.K. and individual applications will not be considered. The awards are for a two-year period, with a stipend of $30,000 in the first year and $33,000 in the second, plus a $750 travel allowance each year. Funding for a third year may be possible by reapplication. The Markey postdoctoral fellowships are for study of fundamental biological phenomena (rather than specific diseases) in fields such as molecular biology, developmental biology, neurobiology, immunology, genetics and virology.

Further information and application forms can be obtained from:

Dr. G. Stark
Imperial Cancer Research Fund
P.O. Box 123
Lincoln's Inn Fields
London WC2A 3PX

Closing date for completed applications is 1st April 1990.

Applicants will be notified by early June and awards can be taken up soon thereafter. (2181)F

Mental Health Foundation

Career Development Fellowships for Research into Mental Disorders

Applications are invited from medical and scientific graduates for a Fellowship for research training in the field of mental disorder.

These awards which are tenable for up to 3 years, are intended for clinicians with a training in psychiatry or intending to train in psychiatry, or postdoctoral scientists who wish to extend their research experience. The research proposals should be relevant to mental health or related basic science and the applicant should intend to continue research in this field. These Fellowships may be held in appropriate departments or clinical centres in Great Britain. The Trustees are prepared to consider a request that part of the Fellowship be spent in a suitable centre, or centres, abroad in cases where the necessary research training cannot all be obtained in Great Britain. Candidates are welcome to discuss their plans with the Honorary Secretary of the Research Committee.

Candidates should not normally be over 32 years of age for science graduates and 34 years for medical graduates. However, consideration will be given to those over this age where their career has been affected either by a late start or by interruption for personal/family reasons. Applications should be made jointly with the Head of the Department in which the candidate proposes to work. Salaries will be in the range of University Lecturer or NHS Registrar scales (whichever is appropriate) according to age and experience.

Application forms can be obtained by writing to
The Secretary of the Research Committee,
The Mental Health Foundation, 8 Hallam Street, London W1N 6DH.

Applications must be returned by March 1st.
(Late applications will not be considered). (2242)E

MOORFIELDS EYE HOSPITAL
HOCK FELLOWSHIP IN OPHTHALMOLOGY

Thanks to the generosity of the original donors, a new fellowship has been established, tenable for three years at Moorfields Eye Hospital and/or at the Institute of Ophthalmology.

The research undertaken by the successful fellow should contribute to knowledge of diseases of the retina and vitreous. Renumeration will depend upon experience, but it will be up to Lecturer grade. The proposed research will be supervised by a Head of Department at the Institute of Ophthalmology. Candidates should ensure that the details of their project have been approved by their supervisor before submitting the application for the Fellowship.

Applications, together with C.V.s and the names of two referees should be received by 18th January 1990.

Medical Staffing Officer, Moorfields Eye Hospital, City Road, LONDON EC1V 2PD. (2246)E

1990 BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Applications are invited by the Trustees, for up to six Beit Memorial Fellowships for Medical Research. The aim of the Fellowships is to promote the advancement by research of medicine and the allied sciences in their relation to medicine. One or two of the Fellowships will be awarded to a candidate whose research proposals are judged to reach the appropriate standard and to bring benefit to the inhabitants of Zimbabwe, Malawi or Zambia, but separate application is not required. The salary will be in the range of a Lecturer or Clinical Lecturer, according to age, previous experience and qualifications of the applicant (maximum starting salary in the range £11,088-£15,372 pa plus London Allowance of £1,650 where appropriate). There will be the usual University superannuation contributions and benefits. Some reseach expenses may be granted on application. The usual tenure of a Fellowship is three years.

Eligibility — in conformity with the conditions under which the Fellowships were first established, every Fellow shall be a man or woman of any nationality whatsoever who at the date of election shall have taken a degree in any faculty in any University approved by the Trustees, in the U.K. or an any Country which is or has been since 1910 a Dominion, Protectorate or Mandated Territory of the Crown. Elections to the Fellowships are rarely made above the age of 35 years. Candidates must submit written evidence that they will be given accommodation in the department where they propose to work which must be in Great Britian or Ireland and their research proposal must be agreed with and confirmed in writing by the Head of the Department.

Forms of application and information may be obtained by writing to **Miss D Billington, Admin. Secretary, Beit Memorial Fellowships for Medical Research, The School of Pharmacy, 29-39 Brunswick Square, London WC1N 1AX. Completed application forms must be received by 15 March 1990.** (2245)E

HOWARD HUGHES MEDICAL INSTITUTE

POSTDOCTORAL RESEARCH FELLOWSHIPS FOR PHYSICIANS

1990 Competition

Fellowships are for full-time training in fundamental research on basic biological processes and disease mechanisms.

Fellowship Terms

3 years of support
$35,000-$50,000 stipend
$15,000 research allowance
$12,000 institutional allowance

Eligibility

M.D., M.D./Ph.D., D.O.
At the start of the fellowship
at least two years of clinical training and
no more than three years of research training
No citizenship requirements

Schedule

Application deadline: **March 1, 1990**
Awards announced: **October 1990**
Fellowships start: **January 1991 — July 1992**

For Program Announcements and Applications

Howard Hughes Medical Institute
Office of Grants and Special Programs
6701 Rockledge Drive
Bethesda, MD 20817
United States of America
Telephone (301) 571-0324

The Howard Hughes Medical Institute, an Equal Opportunity Employer, welcomes applications from all qualified candidates and encourages women and members of minority groups to apply.

(NW4151)E

UNIVERSITY OF WARWICK
Department of Biological Sciences
POSTDOCTORAL FELLOW

The above post is available immediately for suitably qualified candidates with expertise in molecular biology. The successful applicant will join a small team working on biochemical methane oxidation whose current goals are centered on the mechanism of action and site-directed mutagenesis of the hydroxylase component of the enzyme system methane monooxygenase. The fellowship, funded by the Gas Research Institute of Chicago, is available for two and a half years.

Salary will be on the Research IA scale: £10,458 to £16,665 p.a. Further details about the project may be obtained from Dr. J.C. Murrell (0203 523553) or Professor H. Dalton (0203 523552) (direct lines). Application forms from the **Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL,** quoting Ref. No. GRI/BS332/14. *Closing date: 7th January 1990.* (2244)E

UNIVERSITY OF BRISTOL
Department of Pathology
Tumour Invasion and Metastasis

A post-doctoral fellowship funded by the Cancer Research Campaign is available from January 1990 or as soon as possible thereafter for 3 years to work on a project concerning the role of cysteine proteinases and their inhibitors in tumour invasion and metastasis in colorectal carcinogenesis. The person will join an existing team currently working on the cellular and molecular biology of human colorectal carcinogenesis. Experience in biochemistry, cell and/or molecular biology, tissue culture advantageous, although training can be given in these areas.

Salary within the range £10,458–£16,665 (Research 1A) according to age, qualifications and experience.

For further particulars telephone Bristol (0272) 303136 (ansaphone after 5.00 pm) or write to the **Personnel Office, University of Bristol, Senate House, Bristol BS8 1TH.** Further information may be obtained from Dr Rose Maciewicz (0934–852661 ext. 282) or Dr Chris Paraskeva (0272—303454). (2280)E

UNIVERSITY OF OXFORD
DEPARTMENT OF EXPERIMENTAL PSYCHOLOGY
RESEARCH ASSISTANTSHIP(S) IN THE NEUROPHYSIOLOGY OF MEMORY

Applications are invited for postdoctoral or graduate positions to analyse the activity of single neurons in the hippocampus and visual association cortex of the primate. Applications will be particularly welcome from scientists with interests in neurophysiology, mechanisms of learning and memory, and/or information processing in the cerebral cortex. The salaries are on the RS1A scale, £10,458-£16,665, or the RS1B scale £9,816-£14,169. Applications including the names of two referees, or enquiries, to **Dr. E.T. Rolls, University of Oxford, Department of Experimental Psychology, South Parks Road, Oxford OX1 3UD, England.** (2259)P

University of Glasgow
Department of Bacteriology and Immunology

Research Assistantship (Grade 1B) available immediately to join a research group working on different aspects of mucosal immunity. This 3 year project grant, funded by Action Research for the Crippled Child, will develop in vitro models to study the influence of the immune system on intestinal epithelial cells. Candidates should have a good honours degree in cell biology, immunology or a related subject and will be expected to register for a higher degree.

Salary will be £9816 on Research Assistant 1B scale.

Further details from and applications to **Dr. Allan Mowat, Department of Bacteriology and Immunology, Western Infirmary, Glasgow. G11 6NT (041 339 8822 ext. 4498).** (2249)P

POSTDOCTORAL FELLOWSHIPS in the Cognitive Neuroscience of Human Language for Ph.D.'s and M.D.s available immediately at Johns Hopkins' Mind/Brain Institute. The Cognitive Neuroscience program at Johns Hopkins is a multidisciplinary collaboration among researchers in Cognitive Science, Neurology, Neuroradiology, and other departments. Ongoing research emphasizes the functional and neuranatomic organization of language, using the methods of cognitive neuropsychology, behavioral neurology, and direct electrical stimulation and recording from the human cortex, with ^{15}O PET studies planned. The focus of the fellowships will be on cross-disciplinary exposure to research issues and methods; each fellow will have two advisors, from the cognitive sciences and the neurosciences. Positions available for Ph.D.s in Cognitive Psychology, Cognitive Science, Linguistics, Neurophysiology, or Computational Neurobiology, or for M.D.s who have an interest in Behavioral (Cognitive), Neurology. Send application with vita plus 3 letters of recommendation by March 15, 1990 to **Guy M. McKhann, M.D, or Alfonso Caramazza, Ph.D., Co-Directors, Program in Cognitive Neuroscience, c/o Mind/Brain Institute, 114 Jenkins Hall, Johns Hopkins University, 3400 N. Charles St., Baltimore, MD 21218.** *The Johns Hopkins University is an equal opportunity employer.* (NW4671)E

STUDENTSHIPS

ASTON UNIVERSITY
PHARMACEUTICAL SCIENCES INSTITUTE
RESEARCH STUDENTSHIP

available immediately in behavioural pharmacology to work on the role of 5-HT in tic disorders.

Candidates should already have a first or upper second class honours degree in a biological subject and expect to register for a PhD, although candidates for MPhil by research (1 year) will be considered.

Details: **Dr S L Handley 021-359 3611 ext 4182.** (2270)F

OXFORD CENTRE FOR MOLECULAR SCIENCES
STUDENTSHIPS

The Oxford Centre for Molecular Sciences has a number of SERC, MRC and CASE studentship awards available from October 1990. The core research programme of the Centre is based on the following four topics:—

Protein structure and folding (Dr C M Dobson).

Protein specificity and catalysis (Dr L N Johnson).

Protein-protein interactions (Dr I D Campbell).

Protein-small molecule interactions (Professor J E Baldwin).

The OCMS is an interdisciplinary centre with excellent facilities dedicated to the understanding of the structure, function and reactivity of proteins. The Centre's members are drawn from 9 Oxford Science Departments. Successful applicants will have the opportunity to delay their decision on their proposed area or research until they have explored more fully the work of the OCMS.

The Centre has strong links with industry through collaborative projects and the OCMS Industrial Affiliates club.

If you are interested in finding out more about working for a D. Phil in this exciting environment, send a CV with the names of two referees to:

The Administrator, OCMS, Dyson Perrins Laboratory, South Parks Road, Oxford. OX1 3QY.

Closing date for applications: 26 January 1990. (2269)F

Ph.D. Studentships

A number of PhD Studentships will be awarded in 1990 in the Fund's Laboratories in Central London (Lincoln's Inn Fields and Extra Mural Units), at Clare Hall, N. London, Oxford and Edinburgh for full-time studies leading to higher degrees in research fields relevant to cancer.

The awards will be tenable for three years from 1st October 1990 with a taxable grant £9,736 (Inner London), £8,912 (Clare Hall, Outer London), £8,088 (Oxford), and £7,269 (Edinburgh), for the first year and with annual incremental increases thereafter. In some cases additional allowances are payable.

Early applications are invited from candidates, not more than 25 years of age on October 1st 1990, who have been resident in the UK since October 1987 (although non-residents are not excluded from consideration) and who hope to obtain a First or Upper Second Class Honours Degree. Listed below are the Heads of Laboratories with available projects.

1 **Dr J Armstrong**: Ras-Like Proteins in Fission Yeast Membrane Traffic.

2 **Dr D Bentley**: Regulation of Transcription in Differentiation

3 **Dr R Bicknell**: Molecular Mechanisms of Angiogenesis.

4 **Dr D A Cantrell**: Signal Transduction Mechanisms in T Lymphocytes.

5 **Dr M M Coombs**: A Problem of General Relevance in Chemical Carcinogenesis.

6 **Dr J Downward**: Structural and Functional Studies of a Protein that Controls the RAS Oncoproteins.

7 **Dr M Fried**: The Molecular Mechanisms Involved in Mammalian Gene Expression.

8 **Dr A M Frischauf**: Mutated Genes in Hereditary Diseases.

9 **Dr S Goodbourn**: Gene Expression in Embryonal Carcinoma Cells.

10 **Dr P Goodfellow**: Molecular Genetics of Sex Determination and Genome Manipulation.

11 **Prof. A Harris & Dr I Hickson**: Molecular Cloning of a Human DNA Repair Gene.

12 **Dr I Hart**: Molecular Mechanisms of Melanoma Metastasis.

13 **Dr D Ish-Horowicz**: Analysing Transcriptional Control Elements Regulating Striped Expression of the Hairy Segmentation Gene in Drosphila.

14 **Dr N Jones**: Transcriptional Regulation by the Adenovirus EIA Gene.

15 **Dr P Karran**: Regulation of the Expression of a Human DNA Repair Enzyme.

16 **Dr H Land**: Function and Interaction of Co-operating Oncogenes.

17 **Dr H Lehrach**: Molecular Analysis of Mammalian Genes.

18 **Dr M Meuth**: The effect of DNA Structure on the Pattern of Mutation in Mammalian Cells.

19 **Dr M G Parker**: Molecular Aspects of Steroid Hormone Action.

20 **Dr P Parker**: Studies on Protein Kinase C Function.

21 **Dr E Rozengurt**: Early Signals in Mitogenesis.

22 **Dr E Solomon**: Genetic and Physical Mapping of Human Chromosome 17.

23 **Dr M Sternberg**: Prediction of Protein Three-Dimensional Structure from Amino Acid Sequence using Computer Graphics – Application to Transmembrane Helices.

24 **Dr J Taylor**: Analysis of Molecular Events in Breast Cancer.

25 **Dr R Treisman**: Regulation of Gene Expression by Growth Factors.

26 **Dr J Trowsdale**: Organisation and Regulation of Human MHC Gene Expression.

27 **Dr G Warren**: The Mechanism of Receptor-Mediated Endocytosis.

28 **Dr S M Watt & Dr B D Young**: Functional Analysis of Stem Cell Proteins.

29 **Dr S C West**: The Molecular Biology of Genetic Exchange.

30 **Dr J G Williams**: The Regulation of Cell-Type – Specific Gene Expression in Dictyostelium.

31 **Dr R Wolf**: Post-Transcriptional Regulation of Cytochrome P450 Expression.

32 **Prof. N A Wright & Dr R A Goodlad**: Luminal Nutrients and Intestinal Cell Division.

For further details and application form, please write or telephone:

INSTITUTE OF CHILD HEALTH
(University of London)

PhD STUDENTSHIPS
(Minimum value £7,000 p.a.)

Applications are invited for three newly-established PhD studentships to work in the following fields of research in the departments of Immunology (1), Growth and Development (1) and Clinical Biochemistry (1).

Isolation and characterization of the gene responsible for x-linked agammaglobulinaemia (XLA). (Dr C Kinnon).

Purification of the growth hormone-binding protein of human serum and development of specific immunoassay. (Dr D J Morrell).

Molecular Genetics of the Lysomomal Storage Diseases, Fucosidosis and Mannosidosis. (Dr B G Winchester).

All three departments have a wide range of current research interests and have excellent laboratory facilities.

Candidates should normally be not more than 25 years of age on 1st October 1990 and have been ordinarily resident in the UK for a minimum period of 3 years, and either possess, or hope to obtain, a First or Upper Second Class Honours Degree in an appropriate subject.

Further information can be obtained from **The Registrar, The Institute of Child Health, 30 Guildford Street, London WC1N 1EH. Telephone 01-242 9789 Ext: 2679.**

Applications in the form of a Curriculum Vitae and the names of two academic references should be submitted as soon as possible. (2273)F

MEDICAL RESEARCH COUNCIL
MRC Experimental Embryology and Teratology Unit

STUDENTSHIP

Applications from UK citizens are invited for an MRC postgraduate studentship which is tenable for 3 years leading to a PhD degree of the University of London. Areas of research in which the applicant can undertake their studies are the biopsy and analysis of inherited genetic defects in the preimplantation mammalian embryo, or nucleo-cytoplasmic factors regulating early cleavage events of the mouse embryos.

Candidates should possess or expect to obtain a first or upper second class honours degree in developmental, cell or molecular biology or related areas. Curriculum Vitae with names and addresses of two referees should be sent to **Mrs E Kennard, Administrative Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.** (2189)F

MRC
Medical Research Council

GRANTS & SCHOLARSHIPS

Mental Health Foundation

RESEARCH GRANTS

The Research Committee of the Foundation exists to foster and support research in all fields bearing on mental health, mental illness and disorders of mental development.

The Committee meets twice a year to award **RESEARCH GRANTS TO PROVIDE SCIENTIFIC ASSISTANCE, EXPENSES or EQUIPMENT** for research workers.

Closing Dates: March 1st for meeting in May
September 1st for meeting in November.

For Grant application forms and further details apply in writing to:
The Honorary Secretary, The Research Committee,
Mental Health Foundation,
8 Hallam Street, London W1N 6DH. (2241)H

UNIVERSITY OF SOUTHAMPTON
WELLCOME TRUST PRIZE SCHOLARSHIPS FOR POSTGRADUATE STUDY
Biomedical Sciences

Applications are invited for nominations as a Wellcome Trust Prize Scholar at the University of Southampton. Excellent facilities are available in a wide range of subjects including Clinical Biochemistry, Clinical Pharmacology, Surgery, Medical Oncology, Neurosciences and Developmental Biology, and Immunopharmacology (MRC Group).

Applicants should be expecting to obtain a First or good Upper Second Class honours degree at the end of this session or to have graduated with an equivalent degree last year. The terms of the scholarship are particularly favourable (stipend £4,500 per annum, bench fees £2,000 per annum, plus tuition fees).

Requests for further information, stating the specific field of interest, should be sent to the **Medical Faculty Office, Medical and Biological Sciences Building, University of Southampton, Southampton, SO9 3TU.**

Closing date: 23 December 1989.

THE LOUIS JEANTET FOUNDATION FOR MEDICINE

NOMINATIONS FOR THE 1991 AWARDS

Nominations are being sought for the awards of the Louis Jeantet Foundation for Medicine for 1991. One to three awards will be made. They will amount to 1.5 million Swiss Francs (approximately US$1,000,000) in 1991. These awards will provide substantial funds for the support of biomedical research projects (fundamental or clinical) of the highest quality. Candidacies in clinical research are strongly encouraged.

Candidates (either individuals or research groups) must be nominated by scientists, physicians or institutions having detailed knowledge of the candidates' research. The awards are not intended to honour past accomplishments but to help and encourage the laureates' continued research activity. Candidates shortlisted for the final selection will therefore be asked to provide a research project to which the financial support of the award could give decisive impetus.

The previous laureates of the Louis Jeantet Award have been Luc Montagnier (France), Michael Berridge (UK) and Désiré Collen (Belgium) in 1986, Sidney Brenner (UK), Walter Gehring (Switzerland) and Dominique Stehelin (France) in 1987, Bert Sakmann (West Germany), John J. Skehel (UK) and Rolf Zinkernagel (Switzerland) in 1988, Roberto J. Poljak (France), Walter Schaffner (Switzerland) and Greg P. Winter (UK) in 1989. The name(s) of the laureate(s) of the 1990 Louis Jeantet Award will be announced on January 16, 1990.

The following general points should be noted:

1. Applications received directly from candidates will not be considered by the Science Committee.
2. The awards will be limited to researchers working in one of the following countries:
   Austria, Belgium, Denmark, Finland, France, Greece, Ireland, Italy, Norway, Portugal, Spain, Sweden, Switzerland, The Federal Republic of Germany, The Netherlands, The United Kingdom or Yugoslavia,
   although they need not be themselves nationals of any of those countries.
3. All the proposals must be submitted, confidentially, on the official forms only. These are obtainable from:

   The Secretary of the Science Committee
   The Louis Jeantet Foundation for Medicine
   P.O. Box 277
   CH – 1211 GENEVA 17 Malagnou
   Switzerland

   Further information will be sent with the nomination form.
4. The deadline for applications is February 15, 1990.

The name(s) of the laureate(s) of the 1991 Louis Jeantet Award will be announced in January 1991.

Royal Postgraduate Medical School

(University of London)

Immunology Update for Clinicians

A revision course for clinicians and scientists

16–25th May 1990

The course is divided into two parts: part A (days 1–3) provides an introduction to fundamental immunology, part B (days 4–8) is designed to bring participants up to date with the current concepts and progress in this field and to relate these concepts to clinical problems. Students may attend either part, but the course is designed as a continuum.

Topics include:

Part A	*Part B*
Cells involved in the immune response	Receptors on lymphocytes
Cell surface molecules	Complement
Lymphocyte activation	Immune response to viruses
Monoclonal antibodies	Autoimmunity
The major histocompatibility complex	Transplantation
	Immunodeficiency

Speakers include:

Dr F Balkwill
Prof J R Batchelor
Dr J Bell
Dr D Crawford
Dr A Epenetos
Prof F Hay
Dr R I Lechler
Dr P Lydyard
Prof A McMichael
Dr M Owen
Dr A Rees
Dr M A Ritter
Prof K Sikora
Prof M Stewart
Dr J Weber
Dr A Webster

Course Organisers: Dr A Zumla, Dr A N Warrens, Prof J Batchelor, Dr R I Lechler and Dr M A Ritter.

Course fee (inc. catering):

Part A:	**£195**	3 days
Part B:	**£325**	5 days
Parts A & B:	**£480**	8 days

MOLECULAR ENDOCRINOLOGY AND TECHNIQUES FOR HORMONE ACTION

February 18–22, 1990

This course will consist of lectures in methodology with comprehensive syllabus covering receptors, gene transcription, mRNA and protein synthesis, recombinant DNA, protein hormones and cyclic nucleotides.

Co-directors: M. R. Hughes and B. W. O'Malley.

Fee: $365 ($245: fellows and students).

For further information contact: **Bonnie Cuthbert, Department of Cell Biology, Baylor College of Medicine (713)-798-6200.**

DEADLINE—February 2, 1990. (NW4144)C

MARINE BIOLOGICAL LABORATORY

1990 Summer Courses

BIOLOGY OF PARASITISM (June 10-August 10) Daily lectures and laboratory for 16 advanced students on molecular parasitology covering the immunology, molecular biology and biochemistry of the interactions between parasites and their host. Co-Directors: John E. Donelson, University of Iowa School of Medicine and Carole Long, Hahnemann Medical College.

EMBRYOLOGY: CELL DIFFERENTIATION AND GENE EXPRESSION IN EARLY DEVELOPMENT (June 21-July 30) An advanced level course intended for graduate students, postdoctoral fellows, and other research scientists who wish a current treatment of major issues in the experimental analysis of developmental biology of the embryo, and the diverse intellectual approaches now useful in this field. Limited to 24 students. Director: Eric H. Davidson, California Institute of Technology. Assistant Director: J. Richard Whittaker, Marine Biological Laboratory.

MOLECULAR PROBES IN MARINE ECOLOGY: CONCEPTS, TECHNIQUES AND APPLICATIONS (June 17-July 28) An intensive course for graduate students, postdoctoral fellows, and established investigators who wish to learn the techniques of molecular biology and their application to physiological and ecological investigations. Lectures and discussions will accompany the laboratories and will focus on the technologies being learned and applications to specific problems in marine ecology. Limited to 24 students. Director: J. Woodland Hastings, Harvard University.

MICROBIOLOGY: MOLECULAR ASPECTS OF CELLULAR DIVERSITY (June 10-July 26) An intensive course intended for graduate or postdoctoral students as well as established investigators who desire to become competent in microbiological techniques for working with a broad range of microbes. Limited to 20 students. Co-Directors: Martin Dworkin, University of Minnesota and John Breznak, Michigan State University.

NEURAL SYSTEMS AND BEHAVIOR (June 10-August 1) Intended for graduate and postdoctoral students as well as established investigators. The central theme of this course is the neural bases and ontogeny of behaviors. Twenty students participate in intensive laboratories/lectures which combine state-of-the-art neurobiological techniques with behavioral and developmental analyses. Co-Directors: Ronald Calabrese, Emory University and Martha Constantine-Paton, Yale University.

NEUROBIOLOGY (June 10-August 11) For 12 pre- and postdoctoral fellows who intend to work in cellular and molecular neurobiology. Postdoctorals and students at an advanced stage of their graduate training are particularly encouraged to apply. The themes will be the functions of neural cells, the molecules involved in these functions, and the organization of molecular components required to generate cellular activity. Co-Directors: Leonard Kaczmarek, Yale University; Irwin Levitan, Brandeis University; Christopher Miller, Brandeis University.

PHYSIOLOGY: CELL AND MOLECULAR BIOLOGY (June 10-July 21) For a class of 36 graduate students, postdoctoral fellows and established investigators who desire to learn the methods and research strategies used to study physiology at the cellular and molecular levels. Recent college graduates on their way to graduate school and physicians reentering laboratory research are also encouraged to apply. Interested students may apply for 2 weeks of postcourse research starting July 23. Director: Thomas D. Pollard, Johns Hopkins University.

Application Deadline: March 1, 1990
Partial financial aid is available to qualified applicants.
Contact: Admissions Coordinator, Office of Sponsored Programs,
Marine Biological Laboratory, Woods Hole, MA 02543

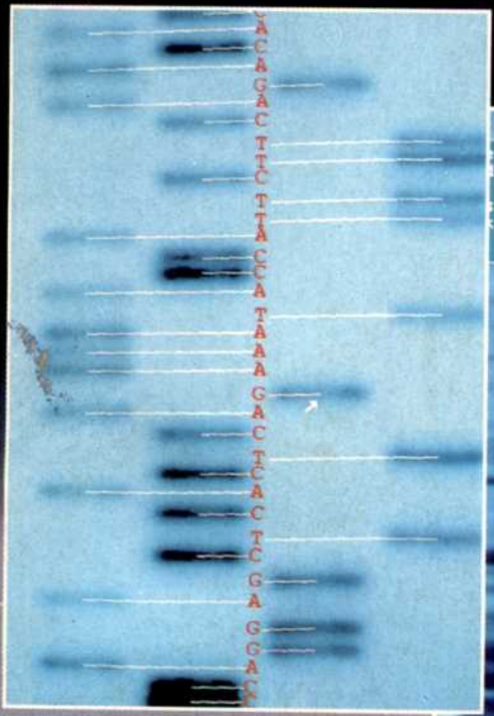
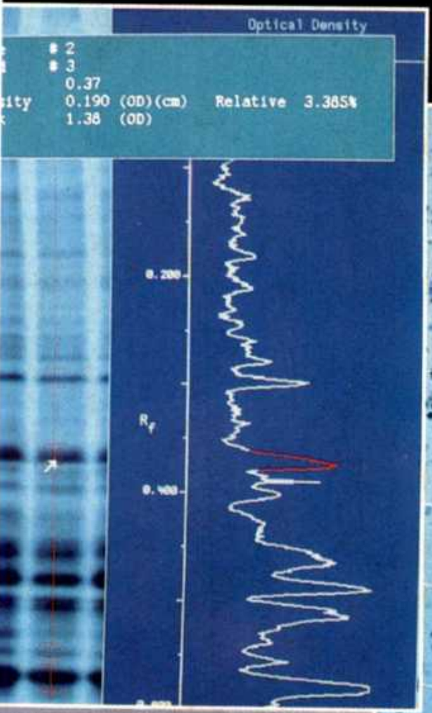
MANTLE PLUMES AND CONTINENTAL DRAINAGE PATTERNS

Now, if it's DNA Sequencing, 1-D gels, Dot Blots, or 2-D gels, it's...

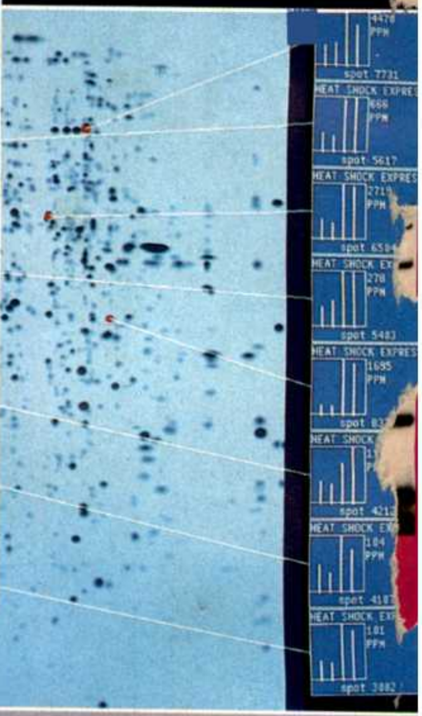
The Discovery Series™



DNA Sequence Reading



1-D Gel Quantitation



2-D Gel Analysis

Discover More

The Discovery Series™ is a system of analysis software packages integrating laser scanning and UNIX® based computing technologies. It's as easy to use as a rule and pencil—only *faster* and more *accurate*!

Produce Results; Don't Just Analyze Data

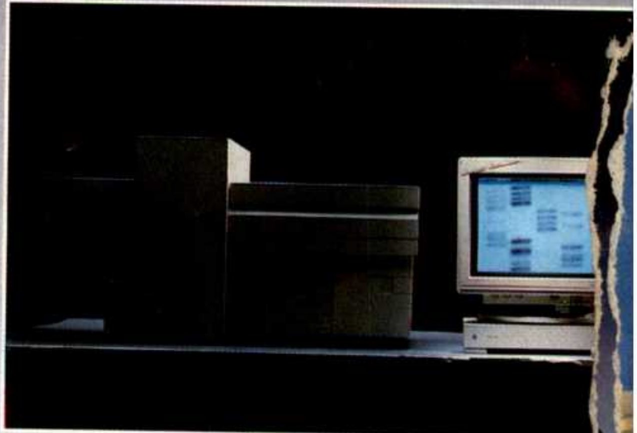
Lay your film, gel or blot on the scanner, pop-up the correct menu on our consistent, logical, user-friendly interface and click your mouse. Whether it's a DNA sequence, quantification of a 1-D gel or making sense out of multiple 2-D gel patterns, The Discovery Series scans the film or gel, analyzes the data and gives you results.

The Software Packages of The Discovery Series

DNA Code™ — For automated, fast and 95% accurate DNA Sequence reading.

Quantity One™ — For quantitative analysis of all types of 1-D gels and Blots.

PDQUEST™ — The world standard for analysis and databasing of 2-D gels.



Introducing the multiapplication software packages of The Discovery Series from Protein Databases, Inc.

Just Picture it...Time to Think

The software performs thousands of tedious analysis tasks and calculations. The routine decisions are automatically done for you; the difficult ones are brought to your attention so that you can make the right decision, quickly. You are thinking about the results, not just analyzing data.

Start on the Road to Discoveri

Call Protein Databases, Inc. today for more information. Over 100 papers have now been pu lished using the power of The Discovery Series Let's work together to make your paper a standout in the next round of significant publications.

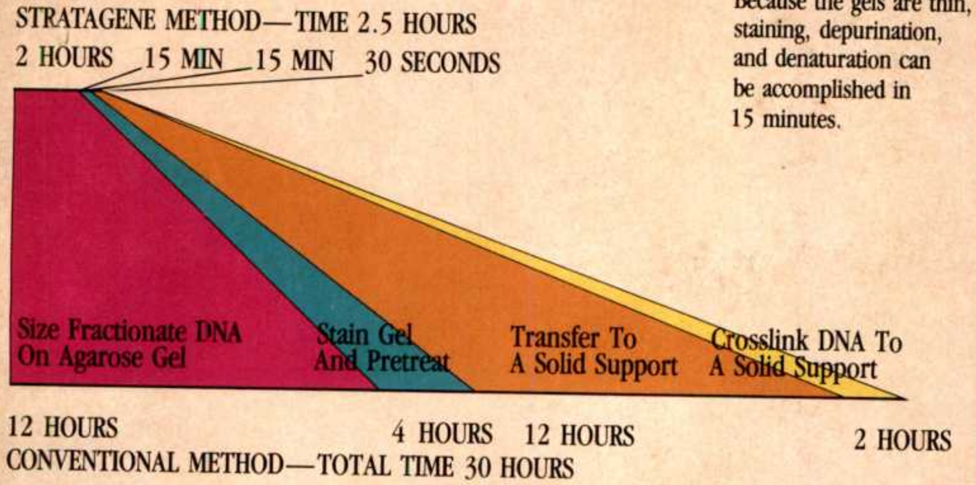
QIAGEN

Southerns/Northerns: Electrophoresis, Blottin and Crosslinking in 2.5 Hours Instead of 3

Stratagene has streamlined agarose gel electrophoresis and blotting. The system decreases the time required, from sample loading to prehybridization ten fold.



VAGE™ System

The VAGE™ vertical agarose/acrylamide gel electrophoresis system allows the casting of agarose or acrylamide gels in the unit. Nucleic acids can be electrophoresed through a 3 mm, 0.8% vertical agaros gel in less than two hours with excellent resolution (Figure 1). Because the gels are thin, staining, depurination, and denaturation can be accomplished in 15 minutes.

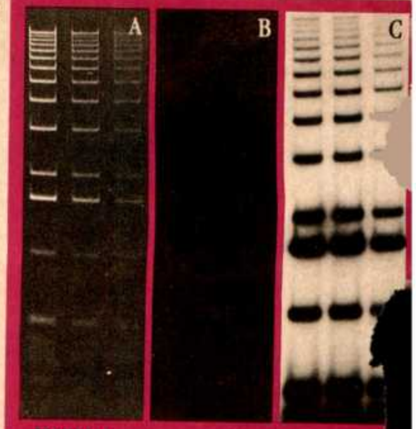


FIGURE 1:

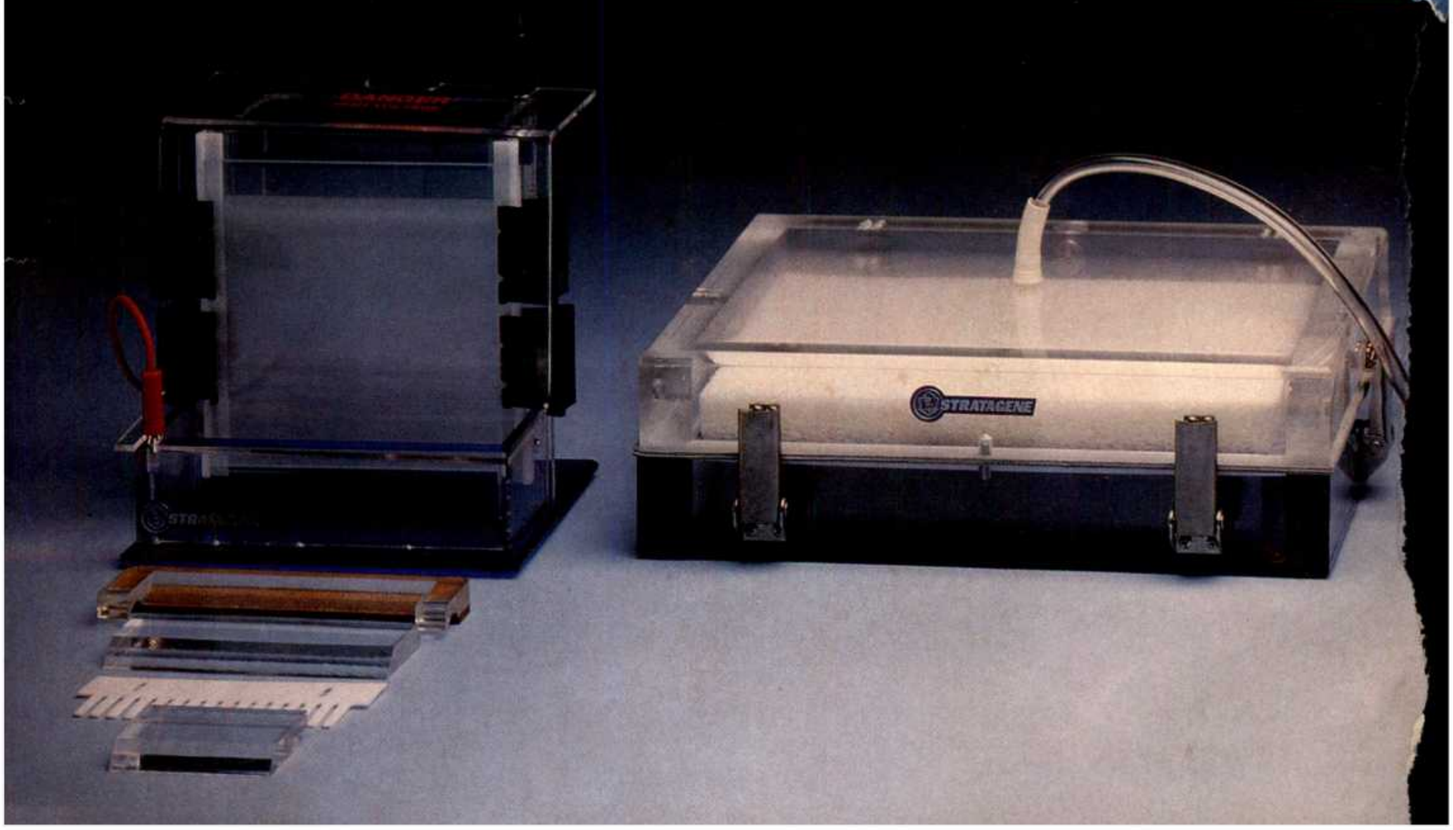
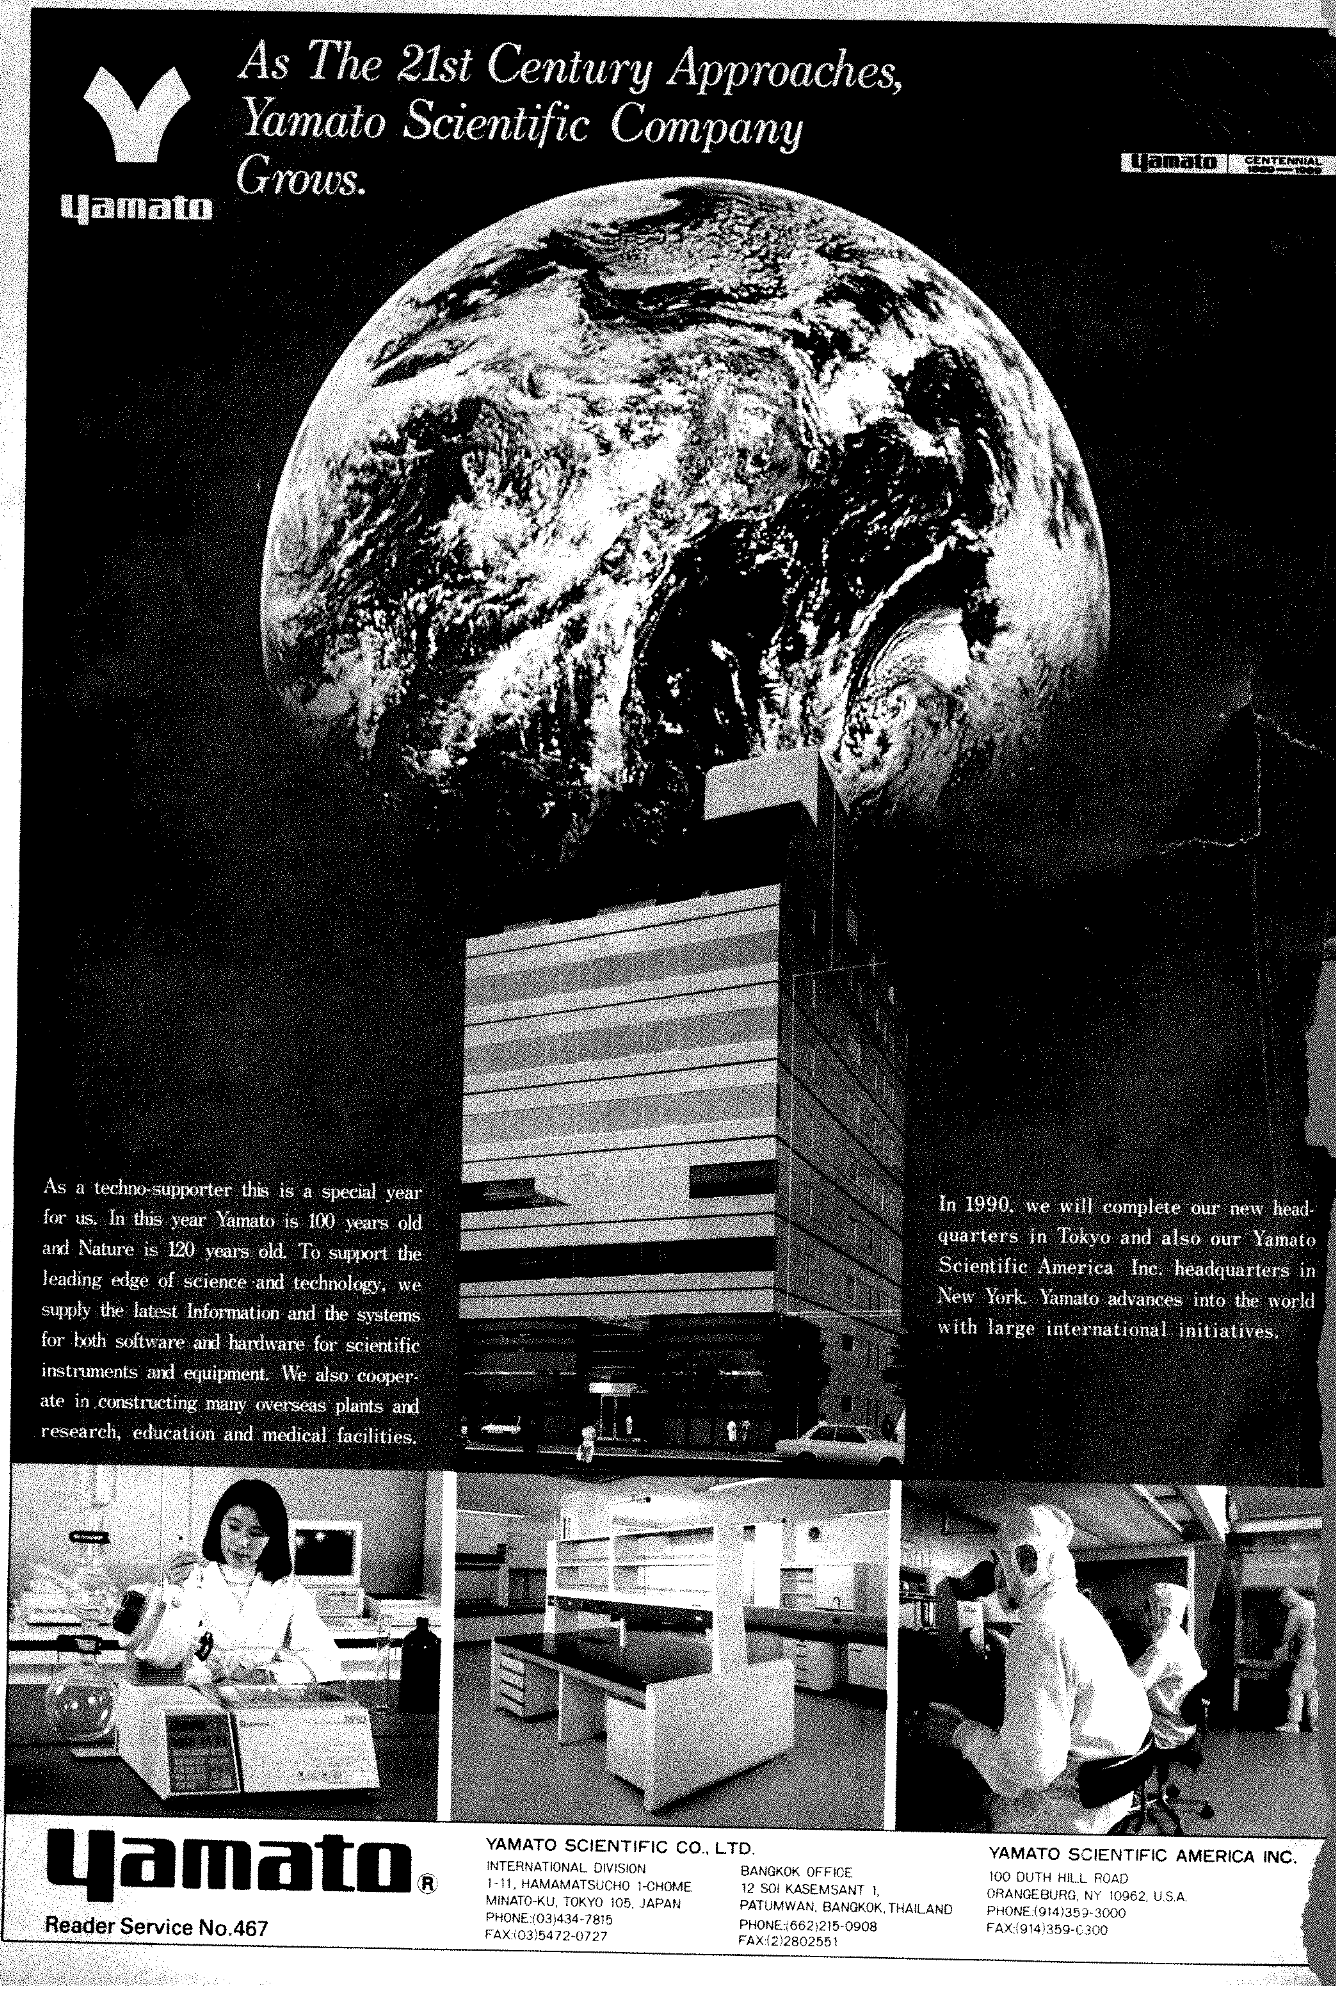
Figure Legend: Fractionation of end labeled DNA markers on 3mm thick 0.8% agarose by the VAGE apparatus and transfer to Duralon—UV™ membranes using the PosiBlot pressure blotter.

- A. Ethidium stained gel showing high resolution.
- B. Same gel after pressure blotting.
- C. Autoradiogram of membrane after pressure transfer.





yamato

As The 21st Century Approaches,
Yamato Scientific Company
Grows.

yamato CENTENNIAL

As a techno-supporter this is a special year for us. In this year Yamato is 100 years old and Nature is 120 years old. To support the leading edge of science and technology, we supply the latest Information and the systems for both software and hardware for scientific instruments and equipment. We also cooperate in constructing many overseas plants and research, education and medical facilities.

In 1990, we will complete our new headquarters in Tokyo and also our Yamato Scientific America Inc. headquarters in New York. Yamato advances into the world with large international initiatives.

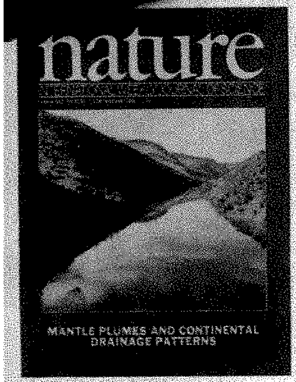
nature

21/28 December 1989
Vol. 342 Issue no. 6252



◀ The Rio Pelotas in southern Brazil, along the border between the Santa Catarina and Rio Grande do Sul states. This river flows west, away from the Atlantic, down the flank of a dome of basaltic lavas uplifted by a mantle plume. See page 873.

THIS WEEK

Volcano predicted

A ten-year study of the Poás volcano in Costa Rica provides the first unambiguous evidence that small changes in gravity can be precursors to a volcanic eruption, and may be of predictive value. Pages 902 and 862.

Setback on male gene

Genetic evidence strongly suggests that the development of testes can be determined by a region of the Y chromosome that does not contain *ZFY*, thought to be the testis-determining gene (page 937) but which now seems in fact to determine spermatogenesis (page 940). See also News and Views page 860.

Antibody construction

The hypothesis that a few key conserved residues in the hypervariable regions of antibody genes determine the main chain conformation of these hypervariable loops is supported by structural predictions, see page 877.

Arresting enzyme

Self fertilization in many flowering plants is prevented by self-incompatibility genes with many alleles, but it has not been known how they work. One of these genes was recently isolated from tobacco and is now shown to have strong similarity to ribonuclease. Ribonuclease activity can be demonstrated in proteins extracted from the plant style where they presumably act on the pollen tube cells to arrest growth. Page 955.

Nitrate source

The 'ozone-unfriendly' greenhouse gas N_2O may be produced in the ocean primarily by production of nitrate (denitrification) not, as was thought, by oxidation of ammonium (nitrification). Page 895.

Rules for waves

Experiments performed in a wave tank show that the moderating effect of rain on wave motions is exerted by the suppression of short-wavelength gravity waves, and the accompanying reduction in the breaking of long waves. The finding affects the validity of some remote sensing data, sea surface radar imaging and radar-based wind speed measurements, page 893.

Lunar find

Evidence from a thin section of the Antarctic meteorite Elephant Moraine 87521 shows it to be of lunar origin. But unlike previously discovered lunar meteorites, it is made up of material from a mare region, rather than from the highlands. Page 889.

Signal splicing

Alternative splicing of the mRNA for the D_2 dopamine receptor, the target of antischizophrenia drugs, gives rise to two forms of the receptor, one of which contains an additional 29 amino-acid fragment in a putative signal transduction loop. Pages 923, 926 and 865.

Membrane fusion arrest

When cells enter mitosis, all intracellular membrane traffic is halted. Experiments with endocytic vesicles *in vitro* suggest that the cell-cycle control protein kinase cdc2 is responsible for this inhibition. Page 942.

Enzyme chaperone

Chaperonins, a ubiquitous class of proteins thought to play a part in the post-translational folding and assembly of other proteins, facilitate the reconstitution of the enzyme ribulose bisphosphate carboxylase (Rubisco) in a stepwise fashion from an unfolded state *in vitro*. Page 884.

Guide to Authors

Facing page 958.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Magazines Ltd (4 Little Essex Street, London WC2R 3LF). Annual subscription for USA and Canada US$295 (institutional/corporate), US$125 (individual making personal payment). USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 1733, Riverton, NJ 08077-7333, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. 10^9 dpm / μg in 2 M

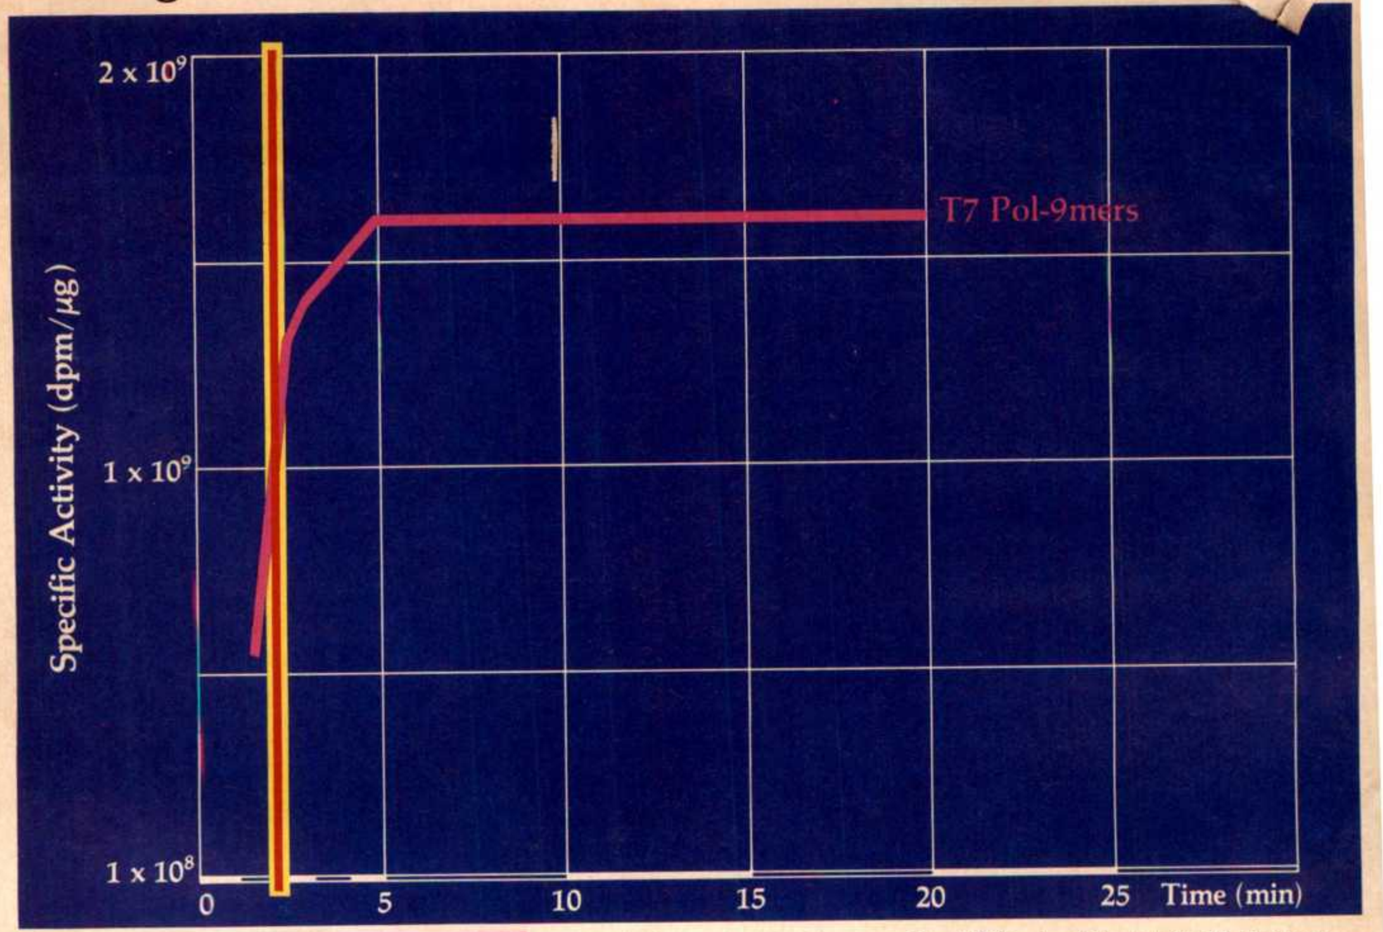
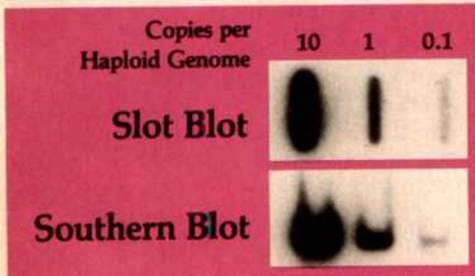
Using The Prime-It™ Random Primer Labeling Ki





Sensitivity of T7-9-mers DNA probe. The sensitivity of a T7 Pol-9-mers generated probe was performed by diluting the 3 kb template DNA to 3.4, 0.34, and 0.03 pg/μl. Twenty μl of each sample were heated in a boiling water bath for 10 minutes to denature the DNA, then each sample was slot blotted onto a Durlon-UV™ nylon membrane. The DNA was UV crosslinked to the membrane in the Stratalinker™ UV crosslinker. The same quantities of denatured template DNA were loaded onto a 0.8% agarose gel and electrophoresed. The DNA was transferred to Durlon-UV nylon membrane and crosslinked to the membrane as before. Both types of blotted membrane were prehybridized for 30 minutes at 42°C in 5 ml of a solution containing 50% formamide - 1% SDS -1M sodium chloride - 10% dextran sulfate. The T7 Pol-9-mers probe was labeled for two minutes as described above. Following purification of the probe to remove unincorporated nucleotides, 2.5×10^6 cpm of the probe was mixed with 200 μl of 10 mg/ml salmon sperm DNA and then heated in a boiling H_2O bath for 10 minutes. The probe was then added to the nylon membranes in a heat sealable bag and incubated overnight at 42°C. Following hybridization, the membranes were washed for 15 minutes in 2X SSC at room temperature and then for 30 minutes in 2X SSC -1% SDS at 65°C. The membranes were blotted dry and exposed to Kodak XAR film for 48 hours at -80°C with one intensifying screen.

Kinetics of polymerization using Stratagene's Prime-It™ Random Primer Labeling Kit. Incorporation of ^{32}P-dCTP into a 3 kb template was measured by mixing together denatured template, random primers, reaction buffer (containing dATP, dGTP, & dTTP), ^{32}P-dCTP (3000 Ci/mmol) and T7 Pol. Incubation was performed at 37°C for 20 minutes. A one μl aliquot of the mixture was removed at various time points and spotted onto DE 81 filter paper discs. The discs were dried, washed, and the radioactivity counted. Total counts added to the mixture were determined by diluting a 1 μl sample in 99 μl of H_2O and then spotting 1μl of this dilution onto a DE 81 filter disc followed by counting the radioactivity. Percent incorporation was measured and specific activity was calculated.

Prime-It™ Random Primer Labeling Kit.

Stratagene has found that T7 DNA Polymerase can utilize random 9-mers oligonucleotides to produce high specific activity DNA probes. Within 2 minutes of incubation, T7 DNA Polymerase and random 9-mers primers produce probes with ideal lengths ranging from 200 to 1000 nucleotides. The specific activity is greater than or equal to 10^9 dpm/μg. The probes can detect as little as 0.1 copy of target DNA. Each kit contains enough reagents to produce 30 probes.

The Molecular Biology of Immune Diseases and the Immun
..........15 Years of Monoclonal Antibodies

For more than two decades, the Symposia have been the premier forum for applied molecular biology. Please join us once again for a double-barreled program highlighting basic research and commercial application:

Plenary Sessions

MONDAY (morning)
Antigen-Specific Receptors
Fred Alt, Columbia
James P. Allison, UC-Berkeley
Harald von Boehmer, Basel Inst.

MONDAY (evening)
Lynen Lecture*
Philippa Marrack
John W. Kappler
National Jewish Center for Immunology And Respiratory Medicine

TUESDAY (morning)
Distinguished Service Award**
Cesar Milstein

TUESDAY (morning)
Antigen Recognition and Lymphocyte Activation
Jack L. Strominger, Harvard
Richard D. Klausner, NIH
Dennis Y. Loh, Washington University

THURSDAY (morning)
Special Achievement Award***
Wallace Coulter, Coulter Electronics

FRIDAY (morning)
Molecular Mediators of Immune Pathogenesis
Kendall A. Smith, Dartmouth
Thomas Malek, University of Miami
Marian E. Koshland, UC-Berkeley
Eckhard R. Podack, University of Miami
Anthony Cerami; Rockefeller University

Molecular Pathogenic Mechanisms

MONDAY (afternoon)
Diseases of Abnormal Antigen Receptor Formation
Ilan R. Kirsch, NCI-NMOB
Hitoshi Sakano, UC-Berkeley
Terence Rabbitts, MRC

TUESDAY (morning)
Molecular Mechanisms in Autoimmunity
Lawrence Steinman, Stanford
Chella S. David, Mayo Medical School
Bonnie Blomberg, University of Miami

TUESDAY (afternoon)
Disordered Regulation of Lymphocyte Activation
Cox Terhorst, Harvard Medical School
Mark L. Tykocinski, Case Western Reserve
Ira H. Pastan, NIH

THURSDAY (morning)
Genetic Disorders of Surface Molecules
Gerald T. Nepom, Virginia Mason Research Center
Bernard F. Mach, University of Geneva
Yee Hon Chin, University of Miami

THURSDAY (afternoon)
Molecular Mechanisms of Immune-Mediated Tissue Injury
Victor Nussenzweig, New York University
Joan Stein-Streilein, University of Miami
Gilla Kaplan, The Rockefeller University

Biotechnology and the Monoclonal Antibody—The Second 15 Years

MONDAY (afternoon)
Receptors, Immunological Structure, and Pharmaceutical Development
Mark I. Greene, University of Pennsylvania
Donald C. Wiley, Harvard
Jeffrey Greve, Molecular Therapeutics
Eckhard Wimmer, SUNY

TUESDAY (morning)
Manipulating the Monoclonal I
James Larrick, Genelabs
Andreas Pluckthun, Max Planck Institute–Martinsreid
Jorge Gavilondo-Cowley, Center for Genetic Engineering and Biotechnology–Havana

TUESDAY (afternoon)
Manipulating the Monoclonal II
Ellen S. Vitetta, University of Texas
Peter G. Schultz, UC-Berkeley
Christopher L. Reading, M.D. Anderson Cancer Center
Sherie L. Morrison, UCLA

THURSDAY (morning)
The Biotechnology of Allergy
Kimishige Ishizaka, Johns Hopkins
Kevin W. Moore, DNAX Research Institute
Jean-Pierre Kinet, NIH
Tse-Wen Chang, Tanox Biosystems

THURSDAY (afternoon)
New Directions in Immunogenetics
Ursula Storb, University of Chicago
Tak W. Mak, University of Toronto
Charles J. Epstein, UC-San Francisco

*Lynen Lecture sponsored by GIBCO/BRL, a division of Life Technologies
**Distinguished Service Award sponsored by Elsevier Science Publishers
***Special Achievement Award sponsored by the University of Miami School of Medicine
****Monday morning Plenary Session sponsored by Boehringer Mannheim

DO, DON'T JANUARY

esponse......... Molecular Pathologies ..

Molecular Pathogenic Mechanisms.
The immune system is an information processing and communication network rivaled only by the nervous system itself. The complexity of its molecular genetics and the subtlety of its cell-to-cell communication—their function and malfunction—have inspired some of the best science of recent decades, research that has provided a wealth of new tools, powerful ideas, and potential products—from vaccines to allergy, from human gene therapy to arthritis and AIDS; from the monoclonal antibody to interferon and erythropoietin.

Biotechnology and the Monoclonal Antibody—The Second 15 Years.
In a decade and a half, the monoclonal antibody has become a dominant force in molecular biology—a cornerstone of successful research and the foundation of nearly every biotechnology product now on the market. The future promises not only hundreds of new applications in familiar modes, but new forms of molecules applied to new kinds of problems—vaccines, anti-cancer therapeutics, drugs for treating heart attack, even the solution to common allergies. We will see how far this still-new technology has come, and try to discern where it will go by 2005.

Posters.
Periods of free communication, in the form of poster sessions, are scheduled for the morning of Jan. 22, the afternoon of Jan. 23, and the morning of Jan. 24. Poster presentations will be published as Short Reports in the Conference Proceedings (IRL Press/Oxford University Press). Authors of selected posters may be asked to give 15-minute oral presentations at general symposia sessions. For more information, please write to Short Reports at the conference address, or call 800-642-4363. **The deadline for poster submissions is November 1, 1989. If your research is relevant, please contact us now.**

Placement Service.
For decades, the Symposia have brought employers and job-seekers together. If you are looking for a position in academia or industry, or are looking for a top candidate, register on the attached coupon,or call.

Workshops.
During non-conference hours, the Symposia's popular technical workshops will offer hands-on introductions to help you master the latest in research tools and concepts.

Hotels.
Reservations for reduced-rate Symposia housing should be made through the central housing office, not through the individual hotels. You will receive housing information when you register. Or call 800-MIA-GENE for more information.

Travel Arrangements.
Discounts of up to 50% are available through the Symposia's agency. Call Travel Services Group at 800-336-0227 for details. Please refer to the Miami Bio/Technology Winter Symposia by name.

Sponsors.
The Symposia gratefully acknowledge the support of its major corporate sponsors:

- Elsevier Science Publishers
- GIBCO/BRL-Division of Life Technologies
- The University of Miami School of Medicine
- As well, Genentech has made a financial contribution to the Symposia.
- Boehringer Mannheim is sponsoring the printing of the final program.

Getting in Touch.
If you have any questions, please contact the Miami Bio/Technology Winter Symposia in the most convenient manner.

- By mail: P.O. Box 016129, Miami, FL 33101 U.S.A.
- By courier: Room 6054, Medical Research Building 1600 NW 10th Avenue, Miami, FL 33136
- Leave a toll-free message: 800-MIA-GENE (800-642-4363)
- Phone: 305-547-6265
- Telefax: 305-324-5665
- Telex: 519308

NATURE VOL 342 **nature** 21/28 DECEMBER 1989

Death of a secular saint

Moscow's mourning of the death of Sakharov is understandable, but Sakharov's life has touched all of us in ways that the international research community dares not forget.

IN other times and places, Andrei Dmietrievich Sakharov, who died last week, would have been made a saint. For the past quarter of a century in the Soviet Union, he lived as one. Since his return from exile in Gorky in 1986, the high and mighty have trudged to the tiny kitchen of his Moscow apartment, seeking enlightenment and a little courage. Like the classical saints, Sakharov taught by example, often breathtaking example.

Although all of us everywhere are now in Sakharov's debt, Mr Mikhail Gorbachev is the most conspicuous beneficiary of his turbulent career. The scandalous decision to exile Sakharov was a bankrupt administration's attempt to silence the most distinguished critic of its way of doing business with the courage to speak his mind within the Soviet Union. Exile would have served its purpose if Sakharov had been more easily cowed. In the event, his fortitude during these six years, and his puckish ingenuity in arranging that his opinions continued to circulate, eventually helped to force the election of a reformer as general-secretary of the Soviet Communist Party and then made possible the goal of *perestroika* on which Gorbachev has set his sights. Although Sakharov, pushing for faster change, has latterly been a thorn in his leader's side, Gorbachev did well to acknowledge his debt on Monday morning.

Sakharov's wider contribution to the new temper of Soviet life is the example of his disarming and, often, infuriating directness. His habit was to say what he believed, about personal liberty, nuclear weapons or even the dilemma of Nagorno Karabakh, without calculating in advance what his listeners would think of him for his opinions. Much of the turbulent Congress of People's Deputies now in session has taken its cue from Sakharov. The benefit is that the Soviet people now know how desperate is their plight.

The rest of us have a more subtle debt to pay, arising from Sakharov's sense of professional rectitude. Sakharov was conscripted into military research during the Second World War and, by 1945, had become one of the small group of theoreticians canvassing the feasibility of both the peaceful and the military uses of thermonuclear fusion. As the world knows, the military project was carried through successfully, and Sakharov rewarded with the Order of Lenin (snatched away again when he was exiled). But, from the outset, Sakharov insisted on the dangers inherent in this enterprise. During his own exile to Gorky, he pleaded publicly the cases of others whose plight was even worse, urging that the international community of scientists, "the one real worldwide community that exists today", should shoulder the responsibilities its privileges imply (*Nature* **291**, 184; 1981). How well will the responsibility be discharged now that the prophet is dead? ☐

LIBRARIANS please note: A production problem caused a discontinuity between the end of the 30 November issue (page 578) and the start of the 7 December issue (page 599). The 'missing' pages, 579–598, have not been allotted.

Leaders lead, OK?

With Sakharov gone, Mr Mikhail Gorbachev will have to change his style.

How should Mr Gorbachev comport himself in the interval between now and the time when there is another gadfly to turn attention from his own subversiveness? He himself must fill the vacuum left by Sakharov. But how?

On one cogent view, *perestroika* has already run into the ground: there is nothing in the shops. At a more abstract level, the rouble is overvalued, meaning that there will have to be a real (not a fake) devaluation in the next few months. People will have to pay more for luxuries, of which they have precious few as things are. Then there may be room for a true price reform, from which even Gorbachev has so far shrunk for fear of the trouble it will cause. Between now and a year from now, Gorbachev has to resolve the economic crisis. So far, luck has been on his side.

The truth, much more encouraging, is that time is also on Gorbachev's side, if only in a narrow sense. So much is apparent from the past few weeks, but here is how that logic goes. Who would have thought, just a few weeks back, that the Soviet enterprise required a new regime in East Germany? Now there is such a one, and also in Czechoslovakia. At this rate, it will be Romania next, or even Albania. For the time being, Gorbachev cannot but be pleased; people, it appears, are on the side of change. But how quickly will change be allowed to happen? Not particularly quickly, it appears. In the short run, Gorbachev will have to face the greater difficulty of saying where he stands. Without Sakharov, that will not be easy. ☐

Moscow bids farewell to the nation's dead hero

■ Academician Andrei Sakharov is buried
■ A city pays its respects

Moscow, Monday

THE nation's grief has never been so all-pervading and sincere as now, when Moscow bids farewell to Academician Andrei Sakharov, the "conscience of the nation". The sense of loss compares in its magnitude only to that at Yuri Gagarin's funeral.

The days that have passed since Sakharov's death on 14 December have shown graphically what profound respect he commanded among the people — this once-defamed man of harsh destiny, the father of the Soviet H-bomb, who spent years in exile under Brezhnev for advocating human rights; the man who bewildered the world with dazzling intellectual revelations and brought it the ideas of new thinking, new relations between different systems; and, finally, the first Soviet holder of the Nobel peace prize.

On 17 December, the temperature in Moscow fell to 20 degrees below zero Centigrade. People fell into long and silent lines along Komsomolsky Avenue where the coffin with Sakharov's body was placed in the Youth Centre. The traditional guard of honour over the body was absent this time: instead, taking shifts every 4 or 5 minutes, were People's Deputies, scholars, Sakharov's colleagues in research and public life, members of the Academy of Sciences of the USSR, poets, writers, representatives of numerous democratic movements and societies.

The ceremony ended at midnight instead of the scheduled 5 p.m. A simple yet moving token of the nation's tribute to the dead academician was a heap of red carnations piled up near the coffin, adorned with funeral wreaths contributed by official and unofficial organizations from all parts of the country.

Today, the ceremony has continued at FIAN, the Lebedev Physical Institute, whence a huge manifestation column set out behind the coffin with Sakharov's body, carried on people's shoulders to the Luzhniki Stadium, where the ceremony became a truly national memorial meeting.

The image of the contentious academician will persist in people's memory. A brilliant physicist–theoretician, he became an academician at 32, the youngest in the Soviet Union. His work on the hydrogen bomb, pioneer ideas on thermo-nuclear synthesis and a number of discoveries in other fields brought him recognition as an outstanding scientist.

He was decorated with the Lenin Order, three Stars of the Hero of Socialist Labour, and given the Stalin Prize — and prohibited from leaving the Soviet Union for reasons of state secrecy.

"Among our scientists, he was, as the saying goes, a transparently-honest man", wrote Nikita Khruschchev in his memoirs. "He hated to think that science might be used for the destruction of life, poisoning the atmosphere and slow killing of the people by nuclear pollution."

Yet it was Khrushchev who failed to heed Sakharov's request not to resume nuclear tests in 1961. This is how Sakharov characterized the ensuing series of H-bomb test explosions: "It was terrible. I became a different man after that." He did not quit science, but concentrated on politics and free thinking, officially called dissent and equated to a crime against the state or a psychiatric disease.

Associated Press

Paying tribute — a long line of Muscovites queue outside the Youth Centre.

It was hard to send Sakharov to a psychiatric hospital and he thus became a symbol of conscience and hope. The desperate letters imploring him for help often bore a simple address: "Academician Sakharov, Moscow". And he undertook to defend the persecuted in the press, in court rooms and in public, even when he realized that his efforts would be in vain.

The Brezhnev system took up the challenge. Without official accusation and trial, Sakharov was sent to the city of Gorky, inaccessible to foreigners for state security reasons. (The exile ended in 1986 with a telephone call from Mikhail Gorbachev.) Academicians denounced him, but he was never expelled from the academy even in the darkest days of witch-hunting, much to the credit of that institution. He stayed having retained his firm perturbed by any persecution

In his book *Reflections on ress, Peaceful Coexistence and Intellectual Freedom*, published in the West in 1968, he called for the elimination of the arms race and the solution of global issues — hunger, racism, disproportionate development of nations and environmental pollution. In 1975 he wrote a book *On Knowledge and the World*. The ideas he developed in that book are obviously parallel to those advanced and discussed in the Soviet Union now.

People's Deputy Sakharov considered *perestroika* to be an event of major magnitude for the Soviet Union and the entire world. He wanted this process to be more speedy and radical in this country. He perceived *perestroika* as a harbinger of the times when the patient Soviet people's long-cherished aspirations and hopes would finally come true.

By his nature, he could not stay aloof from what was going on in his country and abroad, and spoke at the Second Congress of People's Deputies on the day of his death. One of the leaders of the parliamentary inter-regional group, Sakharov was loyal to the end to his absolute and irreconcilable civic stand. The nation will forever remember him as a true patriot, a citizen of his country and the world, a person with an open and generous heart and a fighter for justice and the priority of common human values.

Academician Andrei Sakharov was buried at the Vostryakovo Cemetery in Moscow on 18 December 1989.

SPACE STATION

A Mir $10 million

Tokyo

THE Soviet Union has some bargains going in slightly used space stations. But do not rush — the Japanese were there first. Last week, in one of the oddest sales of the decade, a tiny Japanese company capitalized at just $7,000 bought the back-up Mir space station for $10 million.

The Horie Group company has only ten employees and usually does nothing more exciting than organize seminars on space. It bought the station while it was on display at World Design Expo 1989, held in Nagoya from 15 July to 26 November. The space station had been on display earlier at exhibitions in France and Canada but there were no takers.

Horie Group says it has no immediate plans to launch the space station but it will allow Japanese companies interested in developing space technology to study it.

CANCER DRUGS

Restrictions recommended

Tokyo

An advisory body to Japan's Ministry of Health and Welfare is expected to recommend restrictions this week on the use of the world's two top-selling anti-cancer drugs, Krestin and Picibanil.

The drugs are sold only in Japan and bring in hundreds of millions of dollars each year. But they have become the centre of controversy because of their questionable efficacy.

The Central Pharmaceutical Affairs Council is expected to rule that from now on the two drugs should be prescribed only in combination with other chemotherapeutic drugs and should not be prescribed alone. But a leading critic says the council's decision is unlikely to have much effect on prescription of the drugs and claims that there are serious defects in the process of drug re-evaluation which throw into question the council's impartiality.

Both drugs are so-called biological response modifiers — agents that change the body's response to tumour cells. Krestin is an extract of fungus and Picibanil is a penicillin-treated freeze-dried streptococcus. Both were put on the market in the mid-1970s and their combined sales rose rapidly to about ¥80,000 million ($570 million) a year, which is an order of magnitude larger than sales of anti-cancer drugs in the United States, for example (see Commentary, page 850). Total sales so far amount to more than ¥1 million million ($7,000 million).

Cancer experts have questioned the efficacy of Krestin and Picibanil for years and in 1987 the Ministry of Health and Welfare decided to re-evaluate them. Details of the council's recommendations had not been officially released when *Nature* went to press. But a ministry official confirms that recent reports in the Japanese press of the restrictions to be imposed are "more or less accurate".

Masanori Fukushima of Aichi Cancer Center, who has been campaigning to reform Japan's drug approval system, says the reported decision to allow these drugs to continue to be prescribed in combination with other chemotherapeutic agents represents a "gigantic loophole" . The drugs are already usually prescribed in combination with other anti-cancer agents. And a spokesman for Kureha Industrial Company, which developed Krestin, has confirmed that Krestin is "nearly always" prescribed with other chemotherapeutic drugs.

Fukushima questions the ability of the the council's subcommitee on anti-cancer drugs to re-evaluate Krestin and Picibanil impartially. Fukushima points out that two of the seven subcommittee members carried out some of the clinical trials on Krestin which the subcommittee had to re-assess. And a third member is on the editorial board of the journal *Oncologia*, which published their results. Furthermore, *Oncologia* was established and is financed by Kureha.

A Ministry of Health and Welfare official says that the overlap between members of the subcommittee and those that carried out clinical trials "cannot be helped" because the number of suitable experts in Japan is limited. He says that the root of the problem is the lack of government finance for medical research. He points out that the ministry, which finances the larger part of Japan's medical research, has a budget of only about ¥50,000 million ($350 million) per year, less than one tenth that of the US National Institutes of Health. And so "inevitably" Japanese medical researchers have to seek the financial support of pharmaceutical companies by carrying out clinical trials.

He says that almost all Japanese pharmaceutical companies have their own in-house journals for quick publication of clinical trial results. And while sympathizing with Fukushima's proposal that all clinical trial results used in drug assessment should be published in English in international journals he says this is impractical because of the time it takes.

But Fukushima says that there are plenty of internationally known Japanese researchers capable of carrying out assessment of clinical trials. **David Swinbanks**

ENVIRONMENT

Japan accepts ban on drift-net fishing

Tokyo

Under international pressure, Japan last week agreed to stop using massive fishing nets to catch tuna and squid in the South Pacific Ocean, at least for the time being.

Japan, Taiwan and Korea have been severely criticized by South Pacific island nations, New Zealand, the United States and environmentalists for using drift nets up to 60 km in length in the Pacific Ocean (*Nature* 342, 9; 1989).

Last month, Japan and Taiwan refused to join an international ban on drift-net fishing in the Pacific (see *Nature* 342, 726; 1989). But Japan made a quick about-turn last week to avoid conflict with the United States.

The UN resolution endorsed by Japan last Friday calls for a ban from 1 July 1991 in the South Pacific and worldwide from 30 June 1992. But the ban can be waived if "effective conservation and management measures" are taken. And some environmentalists fear that this may provide Japan with a loophole. David Swinbanks

UK UNIVERSITIES

Selling student places

London

The heads of UK universities last week received details of a new system of competitive bidding for undergraduate places in a letter from the Universities Funding Council (UFC). By June 1990, each university will have to say how many undergraduate places it wishes to make available in each subject area by the 1994–95 academic year, and make an 'offer price' per student for each subject.

Guide prices will be issued within the next few weeks, but the letter notes that "in some (if not all) subjects, universities may wish to . . . improve their chances of having their offers accepted in full by quoting a price below the guide price". Where lower offer prices are made, UFC will leave it to individual universities to show that "adequate arrangements exist for assessing . . . academic standards".

After assessing the bids, UFC will inform each university by early 1991 of the number of student places to be supported and the prices for teaching that have been accepted for the 1991–92 academic year, together with provisional figures for the three following years. As well as cost and teaching quality, the UFC says the range of subject provision and the balance between different subjects will be taken into account in the allocation of student places and teaching grants to the universities.

Some subject areas are excluded from the competitive bidding system. Student numbers for medicine, dentistry and veterinary science will be allocated to universities by the UFC and supported at the relevant guide price.

The new system reflects the government's desire for a more market-orientated university system. Sir Peter Swinnerton-Dyer, chief executive of UFC, says that the new arrangements will "increase institutional autonomy and widen student choice as the balance of public funding for higher education moves from centrally provided grants to fees".

The government expects student numbers to increase by just under 10 per cent between 1988–89 and 1992–93, and for there to be a shift towards science and technology. UFC expects an increase of at least 10 per cent by 1994 – 95 but the exact figure will depend on the universities' bids.

The Committee of Vice-Chancellors and Principals (CVCP) was concerned at its meeting last Friday that funding for the universities for 1990–91 may not be sufficient to provide "satisfactory pay settlements". It has also announced the formation of an 'Academic Audit Unit' to review each university's mechanisms for monitoring academic standards. A full statement on the competitive bidding system is now epected in mid-January, after the next CVCP meeting.

Peter Aldhous

ANIMAL RIGHTS

German research fights back

Munich

THE naming of the first "animal protection official" in West Germany has mobilized some of the country's top researchers in defence of the use of animals in research. Although protests from researchers have already led to limits on the power of the new official, the creation of the post reflects the growing political power of animal rights activists. Important changes in the way research with animals is regulated and monitored by the state may follow.

Researchers were so confident of their postion that they supported Minister-President Walter Wallmann (Christian Democrat) of the *Land* of Hesse when he created the new post. Researchers felt that their right to do experiments using animals was effectively protected by West German law.

Every experiment must be approved by a committee consisting of a two-thirds majority of 'experts' from the fields of medicine, biology and veterinary science.

But the man Wallmann nominated, the journalist and animal rights activist Ilya Weiss, was seen as the last person researchers wanted in the job. Researchers are now worried that the fashion of having an 'animal ombudsman' may spread to other *Länder* or to the federal government.

Weiss, who is 36 years old, is due to begin his duties on 1 January. He has been one of the most ardent advocates of the animal liberation movement in West Germany and publicly supported such actions as the 'freeing' of macaques from the research unit of INSERM in Lyons (see *Nature* **339**, 407; 1989). Weiss was the head of a West German animal rights organization, and has conducted a 14-year crusade against the abuse of animals. He once locked himself in a huge cage in a central Frankfurt square for several days in order to dramatize the plight of animals used in research.

Weiss will have two full-time employees and an estimated budget of DM500,000 ($290,000). His official task will be to observe the application of the West German Animal Protection Law in Hesse and to suggest improvements in the interest of animals in both agriculture and research. He will act as an agent for Hesse in animal protection matters on both a national and a European level.

On 30 November, Wallmann met with representatives of the employees' committee at Hoechst AG, the pharmaceutical manufacturer, which is based in Hesse. On 7 December, he met more than a dozen senior researchers and doctors, some of whom came from other *Länder* to warn him of the possible consequences of Weiss's nomination.

Wallmann assured both groups that Hesse would remain an attractive location for research and industry and that he did not intend to limit animal experimentation "as long as it is necessary". Furthermore, he assured researchers that Weiss would have to clear all of his public statements with the government.

Researchers were disappointed, however, that Wallmann did not forbid Weiss access to the documents that researchers must file in order to gain permission to carry out experiments with animals. They fear that Weiss will pass on the contents of the files to animal-rights activists who might attack individual researchers.

Although animal-rights activity receded after the Animal Protection Act was redrafted by parliament in 1985, the potential for activity is still present — the national animal rights organization 'Deutscher Tierschutzbund' has 600,000 members, about one per cent of the population of West Germany. Peter Gutjahr-Löser, who follows the issue for the Max Planck Society, foresees an upsurge of activity.

A spokeswoman for the granting agency Deutsche Forschungsgemeinschaft (DFG), said that DFG preferred to wait and see what else happens in Hesse before taking any public action. It is important, she said, to see if Weiss does his job properly before responding.

Researchers are especially worried that they would lose support if they are forced to fight in public for the cause of animals experimentation instead of just in private meetings with politicians. "If we had to go up against Weiss in a television debate, we would lose", said Wässle, because "we are amateurs and he is a trained professional." Weiss makes blanket statements condemning the use of animals, whereas researchers are trained to explain complicated issues in a qualified and cautious way, said Wässle. There is no doubt about which method comes across better.

Wässle rejected tactics such as sending leaflets to all the physicians in the country asking them to make their patients aware of the medical need for animal experiments. Although such tactics have been used by researchers in the United States, they would be seen as exploitation of the patients in West Germany, he said.

But not all the news is bad for researchers. The history of disagreements within the animal rights movement may reduce the threat to research. Some activists opposed the nomination of Weiss to the post in Hesse because they felt he was too radical.

Gutjahr-Löser admitted that Weiss's nominations "could have some positive effects" by raising the consciousness of researchers about animal rights. But researchers "do not need Weiss to make them think".

It would make more sense, he said, to hire more experts and veterinarians for the animal protection bureaucracy in order to speed up the application process, which has begun to fall far behind the timetable guaranteed by the law, and to increase vigilance against possible abuse of the animals.

Steven Dickman

ANTARCTIC RESEARCH

New Indian base planned on Weddell Sea

New Delhi

INDIA has despatched an expedition team on a chartered ship to the coast of the Weddell Sea in Antarctica with the eventual aim of establishing a new permanent base in that region. Known to be rich in mineral resources, it lies in an area where Britain, Chile and Argentina have overlapping territorial claims.

The 21-member expeditionary team, which left on 4 December, is led by Dr B.K. Raina of the Geological Survey of India. The team includes five scientists and 16 members of the Army, Navy, and Air Force. This is the ninth expedition to Antarctica since 1982, when the Department of Ocean Development (DOD) set up a station named Dakshin Gangotri at 70 degrees south and 12 degrees east. The station, located on shelf ice, began to drift and in 1986 the Indian team set up a second camp about 80 km inland. A permanent base has now been established there.

The expedition to the Weddell Sea area is a sign that India's Antarctic activities will diversify. Vinod K. Gaur, the new Secretary of the Department of Ocean Development says the team will conduct geological studies, and that the department will eventually establish a permanent station there.

India is a consultative member of the Antarctic Treaty and has been a member of the Scientific Committee on Antarctic Research since 1984. So far, the Department of Ocean Development has spent about $30 million on its eight expeditions.

The department intends to purchase a ship for future expeditions and has asked the government for about $60 million for Antarctic research between now and 1995.

India does not recognize the territorial claims in Antarctica of any countries and says its present goals in Antarctica are purely scientific. But it has been stated officially that economic benefits for India can come from knowledge of the krill stock, and a fisheries vessel capable of operating up to 60 degrees latitude is being acquired.

K.S. Jayaraman

PATENT LAW

Talking of harmony

Washington

1989 ends with patent lawyers hopeful that at long last the holy grail of patenting — the international harmonization of patent laws — lies within their sight, if not yet within their grasp. The reason for this surge of optimism is the unexpected success of the World Intellectual Property Organization (WIPO) set up last year in Geneva under UN sponsorship.

Unlike two earlier organizations that attempted harmonization of patent law, WIPO involves 121 countries, not just the patent offices of Europe, the United States and Japan. WIPO sponsored a successful meeting in Geneva in November at which patent experts examined the details of a draft harmonization treaty. It will sponsor a second meeting next June, with the aim of preparing a treaty for a diplomatic conference in June 1991.

The draft treaty that WIPO discussed in November would bring in some striking changes. The most contentious for the United States is a change from a 'first-to-invent' system to the 'first-to-file' system practised in Japan and Europe in which the patent is granted to whoever wins the race to the patent office. Although proponents of the US system contend that it is fairer, the procedures to determine who was first to invent are time-consuming and expensive.

Many of the clauses in the treaty are hotly disputed by all WIPO members, but one that meets with few obstacles is the plan for a uniform 'grace period' — the time before a patent application is filed during which the disclosure of a competing invention cannot influence the granting of a patent. The United States allows a grace period of one year and Japan six months but Europe has no grace period at all. This difference is one of the most troublesome for those filing for patents in several different countries. Most members agree on a 12-month grace period.

A rule that patent applications must be published no later than 18 months after they are filed is strongly supported, with objections only from the United States and New Zealand. The United States complains that it is unfair to publish a patent application because if the patent is not subsequently granted, valuable secrets may be given away. As the US patent office grants patents, on average, about 18 months after the date of application, the United States argues that there is no need for compulsory early publication, especially as much of the information is disseminated in scientific jurnals. But Japan argues that early publication benefits both everybody because it avoids a long period of insecurity during which the contents of patent applications remain unknown.

Japan's preference for early publication is in part explained by the remarkable length of time it takes to examine patents. Not surprisingly, Japan objects to attempts to put a time limit of 18 months on examination of patents. Opposing the United States, United Kingdom, the Soviet Union and others supporting the limit, Japan argues that strict time limits have no place in an international treaty because many unpredictable factors, such as surges in the number of patent applications or a shortage of patent officers, could block even efforts made in good faith to meet them.

One article in the draft treaty which could reduce the enormous number of patents currently clogging up the Japanese system gains universal support. The article broadens the meaning of 'unity of invention', so that technically related features of an invention are all protected under one patent, rather than under several different ones as is now common.

The question of patent lifetime provokes much argument. The draft WIPO treaty would provide 20 years protection. Uruguay is among those that argue that 20 years is too long, and India argues that the term should vary for different fields of

EPO PATENT DISPUTE

Court battle ends at the start

Washington

One of biotechnology's longest-running battles was expected to end last week but now looks set to go into a new round of bargaining and bickering. On Monday 11 December a Boston court ruled that neither of the two protagonists — Genetics Institute of Boston and Amgen Corporation of Thousand Oaks, California — has a clear overall right to produce recombinant erythropoietin (EPO) by genetic engineering. In the short term, the ruling seems to favour Genetics Institute. EPO is a kidney cell protein that stimulates bone marrow red-blood-cell production, and annual worldwide sales are expected to reach between $250 million and $1,000 million.

The ruling, which is complex and runs to 184 pages, validates the central claims of the patents held by the two companies but at the same time doubles the confusion by considering both patents partially invalid and mutally infringing.

The Genetics Institute patent, issued in June 1987 after the company purified EPO from human urine, refers to "homogeneous human EPO", a term that the company claims to include recombinant EPO. The Amgen patent, issued in October 1987, covers the gene, vectors and cells required for production of recombinant EPO, although the patent did not specify the product itself.

Genetics Institute's version of recombinant EPO is called Marogen and is currently only in experimental use in the United States as it has not gained Food and Drug Administration (FDA) approval.

Amgen's recombinant EPO, called Epogen, gained FDA approval in June, 1989 and already has sales of more than $50 million.

The most immediate effect of the court decison may be to make it easier for Genetics Institute to produce Marogen abroad. The Amgen patent has so far prevented Genetics Institute from manufacturing recombinant EPO in the United States. But it has been getting around the restriction by licensing Marogen to Chugai Pharmaceuticals of Japan and importing the product into the United States.

The new ruling found that offshore production of recombinant EPO by Chugai Pharmaceuticals does not infringe the Amgen patent, effectively putting an end to legal action by Amgen designed to prevent the import of Marogen. Even worse for Amgen, the ruling says that Amgen cannot produce Epogen in the United States without infringing the Genetics Institute patent. That puts Amgen in the same boat as Genetics Institute, which cannot produce recombinant EPO without infringing Amgen's patent. Amgen says that the ruling is unlikely to affect the availability of Epogen to patients. The stage looks set for a tussle over some form of cross-licensing agreement.

But Amgen may try to gain an advantage by waiting for the outcome of actions associated with a wider EPO dispute. Amgen has submitted two EPO process patents. If they are granted, Chugai Pharmaceuticals would be prevented from importing recombinant EPO into the United States.

Amgen is also benefiting from 'orphan drug' status for Epogen, granted by FDA for the treatment of anaemia in patients with chronic renal failure. This provides Amgen with a seven-year monopoly in the United States (see *Nature* **339**, 493; 1989). Marogen, which is awaiting FDA approval for sale in the United States, could receive equivalent status if the FDA declares it to be a product distinct from Epogen. If not, an agreement may be negotiated whereby the orphan-drug status of Epogen is shared with Genetics Institute in return for Amgen not paying royalties in a cross-licensing agreement.

Both parties may, however, wish to see a speedy resolution to the dispute as the market for EPO is huge. **Diane Gershon** technology. The decision on patent lifetime will not rest with WIPO, however, but with GATT (General Agreement on Tariffs and Trade), which will be considering harmonizing the term of patent protection in discussions of intellectual property rights next year.

Developing nations will be anxious for terms that recognize their special circumstances — the need to have access to sophisticated drugs at reasonable prices, for example. They intend to meet in Geneva before the June WIPO meeting in order to thrash out a common position on the treaty.

Christine McGourty

AIDS

East Berlin risks grows

Munich

TANGERINES and tape recorders are not all that East Germans are bringing back from their trips to West Berlin. Unless East German citizens take precautions, AIDS may be the next big import from the capitalist West. That is the view that emerged when East German public health official Niels Sönnichsen visited an AIDS self-help group in West Berlin.

Sönnichsen, who is at the East German Ministry of Health, and his counterparts in West Berlin have begun an information and condom distribution campaign. The campaign is unprecedented in East Germany, where AIDS was a taboo subject until just a few weeks ago. It is aimed at homosexual men, the only group currently at high risk for AIDS in East Germany. The main message: practise safe sex while in West Berlin.

With 16 confirmed cases of AIDS and seven deaths, East Germany has always been one of the most AIDS-free countries in Europe. By contrast, West Berlin, a city of about 2 million, has had 882 AIDS cases and 349 deaths, according to the West German Federal Health Office. The number of AIDS virus carriers in West Berlin is estimated to be between 5,000 and 10,000. East Germany, with a population of more than 16 million, is thought to have 200 to 400 carriers.

But many of the West Berliners infected have been intravenous drug users, as many as 40 per cent of whom are thought to carry the virus. As there is virtually no drug trade in East Germany, only homosexuals are thought to be at risk there.

A self-help group, Berliner AIDS-Hilfe, has distributed condoms at homosexual meeting places in West Berlin since the wall was opened. The next step, said spokeswoman Birgit Thomas-Schön, is to give doctors in East Berlin training in diagnosis and counselling. But AIDS cannot be stopped at the border, says Meinrad Koch, head of the AIDS centre of the Federal Health Office in West Berlin.

Steven Dickman

SPACE SHUTTLE

Rescue mission prepared

Washington

THE mission of space shuttle Columbia, scheduled tentatively for launch on 8 January 1990, will be the first occasion on which the shuttle performs a task that was originally intended to have been one of its routine activities — the return to Earth of a satellite put into orbit on a previous shuttle flight. If all goes well, the crew of Columbia will manoeuvre the shuttle next to a cylindrical canister known as the Long Duration Exposure Facility (LDEF), pull it into the cargo bay, and bring it back down to Earth, where scientists will see the outcome of 66 experiments that have been sitting in the cold and the dark for five and a half years.

LDEF, put into orbit in April 1984, is a 12-sided cylinder, 30 feet long and 14 feet in diameter, holding 86 trays that contain a variety of simple experiments in physics, astronomy and biology. It was supposed to stay in low orbit for about a year, but before it could be retrieved, the Challenger explosion of January 1986 grounded the shuttle fleet for three years. This week's [planned] flight is an eleventh-hour mission: Columbia is the only shuttle with a cargo bay big enough to hold LDEF, and if the retrieval attempt fails, LDEF, now in a rapidly decaying orbit, will burn up in the Earth's atmosphere, probably by February next year.

The unexpected length of LDEF's flight, and the consequently aggravated effects of the upper atmosphere on its contents, could turn out to be the biggest problem for some of the experiments on board, according to Ernst Zinner, of Washington University in St Louis, Missouri, who is principal investigator of an experiment to capture interplanetary dust. Zinner's payload on LDEF consists of a number of 'sandwiches' of germanium plates in metallicized plastic foil coatings. Dust particles, travelling at speeds of 10 km per second, penetrate the foil but crash into the germanium and vaporize; the lower-speed fragments should then be retained by the foil coatings, so that the sandwiches retrieved from LDEF should harbour a five-year accumulation of deposited atoms whose isotopic composition will offer clues as to the origin of the dust. But Zinner is worried that some of his germanium sandwiches, placed in trays at the leading edge of the LDEF, will have been poisoned or damaged by the long exposure to atmospheric oxygen, in which case the germanium will contain an inseparable mix of terrestrial and extraterrestrial atoms.

But the unexpectedly long exposure of LDEF to the elements of space should also bring some rewards. Many of the experiments on board were designed to assess the damage suffered by a variety of materials on long exposure to dust, cosmic rays and meteorites, and the body of the LDEF canister itself will be examined closely for pitting and other ill-effects. This whole investigation will add greatly to the sparse body of knowledge on the durability of man-made structures in space, and should provide food for thought for the engineers now designing the space station.

One final LDEF experiment will give schoolchildren across the United States the chance to participate in a little space research. The George W. Park Seed Company of Greenwood, South Carolina, provided 12.5 million tomato seeds in packages loaded on to the LDEF for the Space Exposed Experiments Developed for Students (SEEDS), and set aside another 12.5 million which have been maintained in a sealed environment on the ground since April 1984. The tomato seeds will be divided up into kits of 50 exposed and 50 control seeds, and will be distributed to 250,000 schools as well as to some universities. Students are then free to investigate the effects of space exposure how they choose; young schoolchildren will be able to compare germination rates and times, while university students can look for genetic changes. **David Lindley**

RESEARCH COUNCILS

NERC on the up

London

A "RESURGENCE" in the fortunes of the UK Natural Environment Research Council (NERC) after years of financial attrition, is the optimistic message of the council's report for the year ending 31 March 1989. At a press conference to publicize the report, NERC chairman Professor John Knill described how a 20 per cent rise in government funding over that for 1987–88 reflected "a dramatic change in public and political attitudes to environmental issues".

But the increase in resources available to NERC since the science budget announced in November 1988 did not prevent a 7 per cent cut in staff numbers over the year, a hangover from earlier financial problems. This year's science budget has yet to be allocated among the research councils.

The report also comments on proposals to reorganize the administration and funding of UK environmental research. NERC is opposed to a full merger with the Agriculture and Food Research Council (AFRC), first suggested by the House of Lords select committee on science and technology in October 1988. Nevertheless, there is "considerable logic in a partial merger between AFRC and NERC", perhaps within a division of a single National Research Council. Peter Aldhous

Journals and databanks

SIR—Recent discussions in these pages ("Who's hiding the primary data?" *Nature* **341**, 94; 1989 and "Making good databanks better" **341**, 277; 1989) have praised the goals of the biological databases, pointed out some problems with them, but rejected a role for journals in ensuring their completeness. While we welcome your enthusiasm for our goals, the arguments against the role for journals fail to take account of the facts.

Insistence on deposition of data is seen by you as an unreasonable burden on authors: journals should not be watchdogs; there should be as few obstacles between the author and publication as possible; political, economic and technical restrictions render access to the databases patchy, and it is unreasonable to insist that scientists contribute to a resource that serves them only poorly. Arguments about the workability (there are so many databases nowadays) and enforceability of deposition schemes are also raised.

That journals are watchdogs is already a fact — non-trivial publication standards and review procedures are already in place to ensure the scientific integrity of what they publish. That these procedures are an obstacle between the author and publication does not, of course, justify the creation of others, but the deposition of sequence data is a necessary part of ensuring integrity. It is now common for articles to discuss sequences or structures not actually presented, and even presented sequences would be more accessible in a computer database. Readers cannot assess conclusions based on data they cannot see. Your leading article "Making good databanks better" even stresses that journals should ask for and make available such supporting data as are appropriate. What better way is there to do that than through the centralized databases?

That access to the databases is uneven is true. Any implication that we complacently direct our efforts to the service of a high-tech subcommunity is not. For some less well equipped users, we produce tape formats long-since obsolete. Our CD-ROM is targeted for users in low-investment computer environments. It also contains search software that may help to obviate the need to purchase expensive third-party products.

Nonetheless, inequalities exist: but nor are journals, libraries and scientific equipment equally accessible to all. The decision not to include the Soviet Union in the present tripartite nucleotide sequence database collaboration was based purely on a notion of diminishing returns with increasing numbers of collaborators. We routinely exchange data with them.

The databases, again like journals, libraries and scientific equipment, are as accessible to commercial organizations as to academic researchers. Publication of scientific findings (in databases or journals) renders them available for exploration. For the sequence database, this is no bad thing. The development of software tools for exploring genome data is in its infancy. Maintaining the complete data collections in the public domain allows any group — commercial or academic — to carry out research in this area and promotes a diversity of approaches appropriate at this stage.

The workability and enforceability of our data deposition systems is no longer a matter of debate, a number of journals already operate such systems with total compliance, and our feedback from editors and authors is positive. Also, some attempt to minimize the problems of dealing with multiple databanks is being made. The United States, Japan and Europe all have nucleotide and protein sequence databases (incidentally the DNA Database of Japan is at the National Institute of Genetics in Mishima, not the Riken Laboratory as you suggest). These six sequence databases have agreed to deal with journals in a coordinated manner.

Insofar as the databases are pleading for data, they are reflecting the demands of the scientific community. It is the users — publishing scientists themselves — who need the data. We do all in our power to ensure the completeness of our collections, but the task is enormous. Without the support of the researchers at large, we will serve them poorly. For unpublished, possibly confidential data, deposition can be urged. For published data, our goals are compatible with those of the journals. Network access to our databases has been possible since June 1988; it is not, as you suggest, a thing of the future. Readers of journals enforcing deposition can typically access the data on the day they receive the journal. The two information resources work well together.

On receipt of reasonably documented nucleotide sequence submissions, we issue accession numbers within one week. They are proof of deposition and an unchanging pointer to the data. We feel it would be appropriate for *Nature* to insist that such numbers be presented at some time in the publication process.

MS processing

SIR—*Nature* has done a service to authors in an earlier issue this year by publishing the median times in which it accomplishes each stage of manuscript processing. I hope that other journals will take up the same practice. What would be desirable is that all journals not only report on this matter periodically as *Nature* proposes to do, but also reprint the essential statistics at last compilation on the same page or pages where they give their instructions to authors, page charges, reprint prices and so on. A would-be author could then easily find the information when he especially needs it: that is, when considering the advantages and disadvantages of submitting to a particular journal.

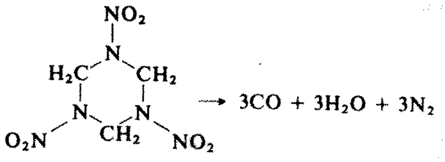
How not to defeat terrorism

SIR—Robert Michaels' suggestion (*Nature* **342**, 336; 1989) that the problem of terrorist bombings of airplanes might be solved by the exclusion of oxygen from the cargo holds of aircraft is ingenious but I am afraid it will not work. Modern molecular explosives, such as TNT, PETN and RDX, do not require oxygen for their detonation but instead contain both oxidant and fuel within the same molecule. For example, the military explosive RDX decomposes on detonation according to the following scheme:



PHILIP N. BARTLETT
Department of Chemistry,
University of Warwick,
Coventry CV4 7AL, UK

SIR—Robert A. Michaels (*Nature* **342**, 336; 1989) proposes to suffocate terrorist bombs by flushing aircraft luggage bins with nitrogen. DREADCO's torpedo experts assure me that explosives are immune from suffocation. They can explode quite happily in nitrogen, or indeed under water. Human beings, however, are not so self-contained. Michaels' system would merely expose the hapless passengers to a new risk — that of suffocation from nitrogen-leaks. On the bright side, however, it would certainly discourage smokers.

Dangerous chemicals

SIR—Wahlström[1] recognizes the ecological and health problems caused by a great number of existing chemicals and suggests a phasing-out procedure for a 'sunset' list. West German activities in this area may be relevant.

In 1982, an Advisory Committee on Existing Chemicals of Environmental Relevance (BUA), consisting of representatives from science, industry and government, was established at the Society of German Chemists (GDCh). Under the German Chemicals Act, existing chemicals must be reported to the competent authority if they exhibit properties indicating they may be hazardous, either alone or in combination with other chemicals (§ 4(6) ChemG). The goal of that committee is to seek appropriate solutions for dealing with chemicals relevant to health and to the environment by the adoption of voluntary measures. The committee selects and examines existing chemicals for environmental or health purposes as authorized by the German Chemicals Act, using exclusively scientific criteria.

The estimated number of about 100,000 chemicals in the European Inventory of Existing Commercial Substances (EINECS) prevents selection on the basis of strictly quantitative criteria. Even if the necessary resources were available, reliable data for a quantitative evaluation are lacking in most cases.

On the basis of the limited data available, a pragmatic approach has been developed for selection. To this end, a list of chemicals was compiled from various priority lists: the presence of these chemicals in the environment has been proved, or is highly probable; they are industrially important, or are manufactured in large quantities. Approximately 4,500 chemicals were selected in this way, of which about 1,000 were selected because of their occurrence in the environment and their industrial relevance.

After elimination of chemicals subject to special legal regulations, materials of natural origin, inorganic chemicals and chemicals that are unstable in the environment, 512 substances remained. For these substances, data were collected according to eight selection criteria covering environmental exposure and effects. These data were scored in a scoring procedure for selection purposes. The result was a list of 60 chemicals that may be of environmental relevance and which consequently should be treated with priority[2].

In continuation of this work, a second list of 75 environmentally relevant chemicals was published[3]. There, the production volume of these chemicals served as an additional criterion. The second list is associated with considerable uncertainty because of the partial incompleteness of the data and because their scientific quality could not be checked individually in all cases. This means that, as with the chemicals on the first list, the second list may also include substances that are not hazardous to the environment, and also that some environmentally hazardous chemicals have been omitted. Consequently, a conclusive evaluation is feasible only if all available data have been collected in separate substance reports and if data that may be lacking have been obtained by appropriate testing.

Meanwhile, about 40 such individual substance reports have been published and about 80 reports are being discussed or about to be published. The importance of these substance reports can be illustrated by an example. In the case of pentachlorophenol (PCP), production in West Germany has been shut down voluntarily as a consequence of the report because PCP is considered as a major source of dioxins in the environment[4]. It is disappointing that companies in other countries have not followed these recommendations, but have even increased their production. As long as non-ecological behaviour leading to more profit governs our decisions, no solution to our environmental problems can be expected.

A third priority list is in the process of being evaluated by an *ad hoc* working group of the advisory committee. In addition, regular scientific symposia provide a platform for the presentation and discussion of the results to the scientific community and the public. Two such symposia have so far been organized under the auspices of the Society of German Chemists.

In conclusion, the commendable five-step phasing-out procedure suggested by Wahlström has already been realized on a national basis in the West Germany. The selection criteria and priority lists developed by the Advisory Committee on Existing Chemicals of Environmental Relevance could also serve as an international model.

Counting partners

SIR—It is true that the average (lifetime) number of heterosexual partners per person should be the same for men and women (*Nature* **342**, 12; 1989), but this will be apparent only if the total population is known. Concentration of promiscuity in a small minority of women will cause most samples to show a wide difference between the sexes.

To take a hypothetical example: suppose a population of 10,000 men and 10,000 women in which 9,990 of the women and 1,000 of the men have been faithful to their partners, and in which the remaining 10 women have earned their living by making themselves available to each and every one of the remaining 9,000 men; almost all samples will show the average number of partners as one for the women and ten for the men.

It should not be supposed that most informants have lied but that researchers have had difficulty in finding sufficient numbers of highly promiscuous women. All the more reason for expanding the research!

Embryo research

SIR—The dilemma facing the British government in implementing the Warnock recommendations[1] is that, if experimentation with or destruction of artificially fertilized embryos is prohibited after 14 days, anti-abortionists could demand the same protection for naturally fertilized embryos. One solution is to scrap the arbitrary 14-day limit.

The German government has chosen a second solution. It is about to legislate against any embryo research which is not for that embryo's own benefit. In so doing, the German government is acting on the Nuremberg Codex developed after the Nazi war-crimes trials[2]. Should this not give us pause?

Certain German scientists and doctors rationalized, supported and even participated in the Holocaust[3,4]. This fact is now universally abhorred. But how many of us would not have been among them, given normal concerns for personal and family security and also career pressures? If this is so, we must now ask how many of today's scientific lobby for embryo research are free of such concerns and pressures. If not thus free, may not today's lobby be equally mistaken?

The overdose of drugs in Japan

Masanori Fukushima

The Japanese consume enormous amounts of drugs on prescription, some of which are not legally available elsewhere in the world. The reason is a defective national system for drug approval and dispensing.

THE Japanese are the world's highest spenders on prescription drugs. Among the top-selling drugs are anti-cancer agents peculiar to Japan that are of questionable efficacy and yet have sales of hundreds of millions of dollars each year, far more than the sales of anti-cancer drugs in other developed nations. Moreover, several of the drugs sold only in Japan have serious side effects. Justification of these contentions is to be found in Tables 1–3.

What has caused this worrying situation? And how can drugs be million-dollar sellers in Japan and yet not sell elsewhere in the world? The answer is that there is a whole series of defects in Japan's drug-approval process and in the system for dispensing approved drugs.

At first sight, Japan's system of clinical trials resembles that of some other countries. In principle, drugs must pass through three phases of clinical trials as, for example, in the United States. Phase 1 is to check a drug's safety in humans; phase 2 is to assess its therapeutic index (the response rate and the severity of side effects) in selected populations of patients for whom the drug is intended; and phase 3 is to determine whether the new treatment is better than existing ones. In the case of anti-cancer drugs, however, once a drug has passed phase 2 it can be widely prescribed throughout Japan. The phase 3 clinical trials in effect become part of the pharmaceutical company's marketing strategy. Further, they do not meet the rigorous requirements of such trials elsewhere in the world — they tend to assess effect only (reduction in tumour size, for example), which is measured during phase 2 trials, rather than benefit (risk-to-benefit, and cost-to-benefit), which is measured during phase 3. So drugs which have some effect but are of little proven benefit can reach the market.

A further disturbing feature is that patients are often given drugs under trial without being asked for their informed consent — that is, without it being explained to them that the drug is experimental, or obtaining their signature on a specific document outlining certain details about the particular study and acknowledging the patient's willingness to participate in it. In the United States and other developed countries, patients involved in clinical trials must fill out and sign detailed consent forms. Thus many drugs that sell well in Japan cannot be sold elsewhere because satisfactory phase 3 trials have not been carried out.

In contrast with conditions in countries such as Britain, where doctors are not allowed to sell drugs, nearly all Japanese general practitioners and hospitals have their own pharmacies for outpatients. Every two years, the Ministry of Health and Welfare (MHW) sets 'official' prices for all drugs, and these prices are supposed to determine the charges to patients and the national health insurance system. But pharmaceutical companies, as a matter of standard marketing strategy, offer the drugs to hospitals at a discount. The permitted discount is 10 per cent, but currently discounts are typically 20–30 per cent or more, particularly when several companies are competing for a share of the market. There is thus a tremendous financial incentive for doctors to prescribe drugs excessively and unnecessarily because they make a profit on every sale. Those new to Japan are often surprised when they go to a doctor with a simple cold and are given an injection of vitamin B and are loaded with drugs to take away. Another odd feature is that drugs are unlabelled, so patients do not know what they are taking.

TABLE 1 Sales of pharmaceuticals for human consumption, 1987

Country	Sales ($ × 10^9)	Expediture per capita ($)
United States	28.965	109
Japan	22.698	166
West Germany	7.606	136
France	6.754	128

Apart from being a massive drain on the national health system and on the pockets of patients, over-prescription and over-use of drugs has had some disastrous consequences. A classic example is that of blood products. In the early 1980s Japanese pharmaceutical companies began to import large amounts of cheap blood products from the United States, selling them to hospitals and doctors at well below the official price. By 1985 annual per capita blood-product consumption in Japan had risen to about three times that of Britain and France[1]. Coincident with the surge in imports, AIDS was introduced to Japan in non-heat-treated blood coagulants used for the treatment of haemophiliacs. Japan has about 1,000 carriers of AIDS, more than 90 per cent of whom are haemophiliacs.

Other examples are the anti-cancer drugs PS-K (Krestin), OK-432 (Picibanil) and Tegafur, all available only in Japan. Research on Tegafur has been abandoned elsewhere in the world[2], but in Japan Tegafur, together with Tegafur uracil, has annual sales of $280 million (Table 2). PS-K and OK-432 are widely prescribed — PS-K for cancers of the digestive organs (stomach, oesophagus, colon and rectum), lung and breast; OK-432 for cancers of digestive organs (stomach, liver, biliary tract, colon and rectum), head, neck, thyroid and lung. Total sales of these and other anti-cancer drugs peculiar to Japan are about $1,000 million per year. But have these enormous expenditures resulted in an increased number of lives saved? The simple answer is probably no.

Since the mid-1960s, survival rates for various cancers have steadily improved, but comparison of the rates with those of other countries where these drugs are not available[3] shows no evidence of increased survival in Japan (Table 4). The exception

TABLE 2 Top-selling anti-cancer drugs in Japan and the United States, 1987

Japan				United States

Source: ref. 3. *Figures are percentages.

PS-K is of very doubtful efficacy. Studies during clinical trials seem to show some evidence of increased survival among cancer patients[4-6], but most of the research was published in company-financed or company-related journals; the only report in an international journal is a review of the Japanese work[7]. Although comparative studies were carried out in these clinical trials, they were severely flawed. For phase 3 studies, for example, disqualifications are a source of potential bias[8]. In the trials the disqualification rates for major end-points were 18 to 36 per cent, greater than the magnitude of the differences in outcomes tested. Furthermore, there was no assessment of whether patients complied with the requirements of the protocol, no description of procedures to ensure that the data are reliable and no analysis of whether there were significant deviations in findings from one institution to another. Also, the results have not yet been reproduced.

The MHW has reinvestigated the efficacy of OK-432 and PS-K, and a decision to restrict their use to combinations with other chemotherapeutic agents is imminent, according to Japanese newspaper reports. But as the drugs are usually used in combination with other agents, this is unlikely to have much effect on prescriptions and sales.

So why is PS-K so widely used despite its questionable efficacy? One reason is that it has no side effects. In Japan, doctors tend not to tell their patients if they have cancer, reasoning that the shock might kill them. PS-K is thus a handy drug to prescribe as it is taken orally and has none of the tell-tale side effects (such as hair loss) of anti-cancer drugs used in the West. Another reason is that most Japanese doctors are unfamiliar with the discipline of medical oncology. Finally, once a drug has passed clinical trials, the MHW tends to approve it for a wide range of related diseases without assessing its therapeutic efficacy or clinical usefulness for each disease. MHW has approved the use of interferon-α for kidney cancer and multiple melamona, and that of interferon-β for glioma and melanoma, for example. But although interferon can produce some response in tumours of these cancers, at present there is no evidence of an increased survival rate among patients. In the United States, the FDA has approved interferon-α only for hairy-cell leukaemia and melanoma.

To understand why there are so many dubious drugs on the Japanese market, one has to understand the unhealthily close relationship that exists between doctors, pharmaceutical companies and the MHW. Data presented to the MHW for approval are in mainly in the form of unpublished results or of reports published in Japanese in company-financed or company-related journals. Those in charge of clinical trials often set up their own foundations, funded by the pharmaceutical companies, for which they organize clinical trials. And often some heads of clinical trials also belong to the drug-approval committee. Thus a data-producing mechanism by the company for the company is inherent in the system.

What can be done? As some first steps I suggest the following.

- Only data published in leading international journals should be acceptable, and the work of more than one group of researchers must be available for evaluation; claims for drug effectiveness appearing in Japanese journals (except scientific society journals) should be discounted, as should unpublished results.
- The published evidence should be checked by referring to the individual patient's chart, and the data on the drug's toxicity and adverse effects should be examined.
- The MHW staff must be able to judge whether or not the papers are scientifically sound. The diagnostic criterion concerned must be checked and the results strictly interpreted according to the backgrounds of the patients concerned.
- In arriving at a decision, MHW staff must carefully analyse the risk-to-benefit, cost-to-benefit and cost-to-effectiveness factors, and should address questions such as what sort of benefits the drug will have. Needless to say, the members of the approval committee and MHW staff must be scientifically qualified (at present many are not). MHW should also enforce "good clinical practice" (ref. 9) on clinical trials, direct doctors to obtain informed consent properly, encourage them to pursue well-designed and controlled phase 3 studies, and assess adverse drug reactions.
- To cut down on Japan's wasteful consumption of drugs, pharmacies run by hospitals and individual doctors should be abolished and replaced with independent outlets. MHW is moving in this direction (a process called *bungyo*, meaning divide) but very little progress has been made.

Many of the problems I have described stem from the poor quality of science practised by Japanese clinicians, which in turn stems from the inability of most of them to read the foreign literature. But the problems are more deep-rooted than just language. In Japan there is little appreciation of the value of individual thought or philosophy which sustains science and is the spring of new ideas elsewhere — the lack of informed consent in medical practice is just one manifestation of that failing.

It seems that things have not changed much since 1902, when Dr Rintaro Mori (Ougai Mori), pointed out the Japanese were unable to sustain science but were very enthusiastic about eating its fruits. This attitude partly explains why Japanese research tends to be mostly method-orientated and unoriginal, and why some scientific fields created by other developed nations — clinical pharmacology and medical oncology, for example — are not established here. Radical, structural changes are needed if Japan's drug-approval system is to work for the benefit of the public and not for that of the pharmaceutical companies. ☐

Masanori Fukushima is in the Department of Internal Medicine and Laboratory of Chemotherapy, Aichi Cancer Center, Chikusa-ku, Nagoya 464, Japan.

Reflections on the discovery of fission

Rudolf Peierls

Sir Rudolf Peierls adds a personal postscript to a year that marked the fiftieth anniversary of a discovery that helped shape the twentieth century.

THE publication of the paper by Hahn and Strassmann[1] in *Naturwissenschaften* in February 1939, 50 years ago, is rightly considered the essential step in the discovery of fission, although it was preceded by several years of experiments. But the background to this discovery lies much further back.

In 1932, the neutron was discovered by James Chadwick. It was immediately clear that it was a constituent of atomic nuclei, and soon it also became clear that nuclei consist of only neutrons and protons; there are no electrons in nuclei. The electrons emitted in beta decay are created in the act of emission. This insight marked the beginning of nuclear physics as we know it today.

Enrico Fermi in Rome was one of the first to realize that neutrons could become an important tool for studying nuclei. He became excited about this prospect and, although he had previously done important work in theoretical physics, he decided in 1933 to become an experimenter. By 1934 he had built his equipment and started experimental work with a group of collaborators.

The only way to generate neutron beams then was to bombard light elements with charged particles, either alpha particles of the kinds emitted from radioactive sources or protons from an accelerator, such as a cyclotron or a high-voltage installation. Rome had no accelerator, so Fermi was compelled to use the laborious method of directing alpha particles at beryllium.

Early observations

Fermi discovered that, in many elements, slow neutrons are more efficient at hitting nuclei than fast neutrons, which makes the experiment easier, provided one interposes between source and target a subtance containing hydrogen or other light elements, a 'moderator', in which the neutrons can collide with the light nuclei and lose kinetic energy to them.

Even those early observations were a puzzle for the then rudimentary theory of nuclei. It was then generally assumed that one could treat the passage of a neutron through a nucleus in good approximation as if it were moving in a potential field, which would be the average field of the particles inside the target nucleus. This picture, taken over from atomic theory, would of course have to be corrected for exchange of energy between the neutron and particular target nucleons, but this was taken to be a small correction.

On this basis, one would have expected the main result of a neutron–nucleus collision to be elastic scattering of the neutron, with an occasional inelastic event leading to excitation of the nucleus, and only very rarely the capture of the neutron with the emission of radiation. But the experiments showed that neutron capture was a very frequent event — for many nuclei, much more probable than scattering.

These findings completely mystified theoretical physicists until the solution was presented[2] by Bohr in 1936. Briefly, his point was that the constituents of the nucleus are interacting very strongly with each other, and with the incident particle, so that its kinetic energy is shared between many particles, with the result that none of them can escape until enough energy happens to be concentrated on one of them. This means that the neutron must remain in the nucleus for a much longer time than the picture of a single particle in a potential would have predicted and that, during that time, the chance of the emission of a photon is appreciable. In the case of a slow neutron, for which practically the whole excess energy is required for escape, escape becomes a very infrequent event and the emission of radiation dominates.

In most elements, the capture of a neutron produces a nucleus which is beta radioactive. (Artificial beta radioactivity had been discovered by Fréderic and Irène Joliot-Curie in 1933.) For different radioactive nuclei produced in this way, the beta rays have different half-lives, so that it is possible to distinguish the radioactive species formed. By chemical separation of the activated target, one can discover the chemical nature of the radioactive nuclei produced.

After establishing the principles, Fermi and his group bombarded with neutrons all elements they could get hold of, practically the whole periodic system of elements. This exploration produced a large amount of data, from which one could learn much about the properties of nuclei. A particularly interesting case was uranium, because that was the heaviest nucleus and at the end of the periodic system. If uranium captured a neutron it would become heavier. Because the number of neutrons in it would then be too large for the number of protons, it would probably increase its charge by emitting a beta electron and would thus become a new element, not existing in nature — a 'transuranic' element. The experiments on uranium were therefore watched with particular interest.

But the results were very unexpected. Instead of one, or a few, half-lives, the decay curves showed there were several, so many that it was not easy to disentangle the curves and find how many there were. How could neutron capture produce so many different species of nuclei from one element? This was a puzzle that many physicists tried to solve. Could a nucleus be found in many different states, without quickly being transformed to the most stable of them? Examples of such 'isomeric states' were known, though not in such large numbers. Niels Bohr was one of the theoreticians who tried to invoke such isomeric states to explain the behaviour of the alleged 'transuranic elements'.

Some answers

A different answer was proposed by a chemist, Ida Noddack-Tacke, as early as 1934[3]. She started from the fact that in his attempt to identify the chemical nature of the active nuclei, Fermi had looked only at elements of atomic number Z above 82, because none of the reactions known or imagined in nuclear physics could have resulted in a lower Z. Noddack-Tacke suggested that perhaps the uranium nucleus could have split into several sizeable pieces, whose atomic number then would be much smaller. So the experimenters should therefore look for activities following the chemical behaviour of much lighter atoms.

Nobody seems to have taken this suggestion seriously. Fermi (to whom the author presumably sent a copy of her paper) said such a capture of the neutron would not be sufficient to overcome the forces holding the nucleus together. Probably others who saw the paper also had difficulty in accepting the idea of a reaction that was so different from what had ever been seen.

Efforts to resolve the puzzle continued for many years. In Berlin, Hahn, Lise Meitner and Strassmann did painstaking chemical analyses to identify the chemical properties of the radioactive nuclei created. Joliot-Curie and Pavel Savich analysed one particular activity very carefully and found that it appeared to belong to an element with chemical properties indistinguishable from lanthanum, which saw the situation more or less as Landau saw it, but nobody published such speculations.

So it was natural that after the discovery of fission the question arose whether the fission was accompanied by the emission of secondary neutrons. The first positive answer to this question was reported by Joliot's group in Paris[11]. Their estimate of the number of neutrons per fission was somewhat high. More accurate measurements were done a little later by Fermi's group at Columbia University, New York[12].

A chain reaction requires that, of the neutrons released in the fission of one nucleus, more than one neutron should cause the fission of another nucleus. This requires that the loss of neutrons by other processes be below a certain limit; if this condition is met, there will be a critical size, because in too small an amount of material, the proportion of neutrons leaving the body before hitting a uranium nucleus would be too large.

By now, the possibility of a chain reaction had become more real, but there were still difficulties. As Bohr had pointed out, the abundant isotope ^{238}U can be split only by fast neutrons with energy above a threshold now known to be about 1 MeV. Only a fraction of the neutrons created in the fission process have such high energies, and they tend to lose energy by inelastic collisions.

The large effect of slow neutrons on ^{235}U suggested slowing down the fission neutrons by adding to the uranium a moderator, that is, a light element. The neutrons collide with the atoms of the moderator and thereby lose energy. But the moderator also absorbs some neutrons, and for most light elements the absorption is great enough to reduce the average number of neutrons per fission to less than unity, thus making a chain reaction impossible. Moderators that have been used successfully with natural uranium are carbon, in the form of graphite, and heavy water (D_2O).

Fermi succeeded in making the first chain reaction by using a graphite moderator. For this, commercially pure graphite would not do because certain impurities can absorb too many neutrons even if they are present in concentrations undetectable by chemical means. Fermi insisted on further purification, in the belief that there were still excessive impurities, and indeed the absorption of neutrons was reduced below the critical level. With this purified graphite the first chain reaction was produced by Fermi's group in Chicago on 2 December 1942.

The success of this experiment opened the way to the release of nuclear energy on a macroscopic scale. The most obvious application was to power generation. This would consist of reactors working in principle like Fermi's first experimental one, but with arrangements for heat transfer, which allowed the heat generated in the uranium to be passed to steam generators or other devices for driving machinery. There were of course many practical problems to be overcome, but they were technological rather than nuclear physics problems.

Another application was to the production of radioactive isotopes, which are useful in many areas of research, and for medical diagnosis and treatment. Nuclear reactors are an abundant source of neutrons, which can be used to bombard various targets and to produce in them a great variety of radioactive species. But at the time all these possibilities were for the future. The world was at war, and interest was concentrated on the third possible application, the nuclear bomb.

Bohr had pointed out that a reactor could not produce a violent explosion. The reactor depends on slow neutrons, which have to travel considerable distances before they cause further fission, so that the development of the chain reaction is slow. When the released energy has heated the reactor to a temperature that will melt or vaporize its materials, the expansion and dispersal will stop the chain reaction. The energy released is therefore only of the order of the cohesive energy of the structure, so that the explosion is no more violent than that from chemical explosives.

In 1940, I was discussing such problems in Birmingham with Frisch, and we felt rather reassured by Bohr's argument, which seemed to show that a fission bomb was impossible. Then, one day, Frisch asked me: "Suppose someone gave you a lot of separated ^{235}U, what then?" This seemed an entirely academic question because the separation of isotopes had been achieved only in gram quantities and only for light elements, where the fractional mass difference of the isotopes is much greater than the roughly 1 difference in uranium.

With ^{235}U, every neutron is capable of causing fission, and one does not need to rely on the especially high capture rate for slow neutrons, so one needs no moderator. We could guess at the nuclear cross-sections from Bohr's theory, and I had a formula ready to give the critical size in terms of the cross-sections. We were staggered to find that the critical size, or mass, was only pounds, instead of the tons one intuitively expected after thinking about reactors.

How much energy would be released in such a fast chain reaction? Now the neutrons were 10,000 times faster than the thermal neutrons effective in the reactor, and they had a much shorter distance to travel. Therefore the build-up of the chain reaction would be fast enough to cover an appreciable fraction of the uranium nuclei before the pressure from the heat developed would disperse the materials and stop the reaction. One would have an explosion of unprecedented power.

It seemed to us that the enormous power of such a weapon would be worth the great effort required to separate the uranium isotopes. This was in 1942, and we feared that Nazi Germany might complete such a weapon first. We knew there was no defence except the threat of retaliation.

We wrote a memorandum to the British authorities, in which we presented our arguments and outlined, as best we could, the implications. We mentioned the fallout and the inevitability of many civilian casualties in almost any use of such a weapon. We did not foresee the fusion bomb, nor the insane arms race.

These arguments were taken seriously by the British government, and this in turn led to an accelerated pace in setting up a large-scale project in the United States — the Manhattan Project. This succeeded in separating large amounts of ^{235}U, but also followed an alternative approach: some of the ^{238}U nuclei capture a neutron to produce ^{239}U which is itself unstable and emits a beta electron to become neptunium-239 (^{239}Np). That, in turn, undergoes rapid beta decay to become plutonium-239 (^{239}Pu), which lives for a long time. It was conjectured from Bohr's theory, and later verified, that in ^{239}Pu, as in ^{239}U, neutrons of any energy would cause fission; it was also weapons material. So another activity of the Manhattan Project was to build large reactors producing plutonium. It is common knowledge that both these methods led to the production of nuclear weapons and that they were used against Japan.

This is not the place to discuss the moral implications of the making and the use of the bomb, or the best way of avoiding nuclear war, or to argue the advantages and dangers of nuclear power. My objective has been to tell the story of the very esoteric work of academic physicists and how in such a short time it developed into applications of enormous military, political and economic importance. ☐

Your aid in climate modelling!

Climate Dynamics

Observational, Theoretical and Computational Research on the Climate System

Climate Dynamics focuses on the dynamics of the entire climate system, including atmosphere, ocean, cryosphere, surface biomass and lithosphere and emphasizes the physical, chemical, and biological coupling or interactions among these components on a wide variety of space and time scales.

Theoretical and/or computational approaches need validation by comparison with the present climate and ancient climate states as revealed by studies of the information contained in natural archives like sediments, organic material and polar ice. It is this interaction which promises progress towards a consistent, integrated understanding of the complex mechanisms governing climate and environment.

The journal publishes observational, theoretical and/or computational papers and attempts to integrate different approaches and work of a more speculative and imaginative nature which might stimulate research.

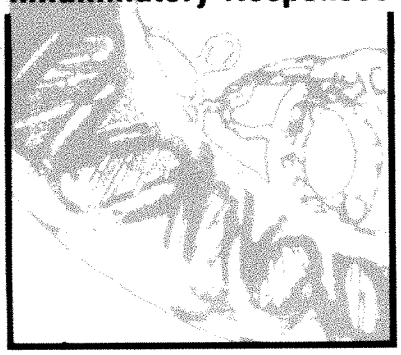
LYMPHOKINES

The Molecular Biology of Regulators of Immune and Inflammatory Responses



By **Ken-Ichi Arai** and **Jan de Vries,** DNAX Research Institute, Palo Alto, CA

This monograph elucidates the complex regulatory network between the immune system and the hemopoietic system which coordinates inflammatory response. Through the use of recombinant DNA technology, a number of lymphokine and cytokine genes, derived from T cells and macrophages, have been isolated, their primary structure determined and the biological properties of their recombinant products examined. These studies have revealed the existence of a regulatory network which can be partly or wholly activated in different ways by unique combinations of lymphokines. In this comprehensive synthesis of current knowledge, Lymphokines presents a clear overview of the structure and biology of lymphokines and of the network controlling immune and inflammatory response.

Contents
General Overview of Lymphokines • Molecular Cloning and Production of Recombinant Lymphokines • Structure and Biology of Major Lymphokines • Structure of Lymphokine Genes and Regulation of Expression in Immune and Hemopoietic Cells • Lymphokine-Receptor Interaction and Signal Transduction • Coordinate Regulation of Immune and Hemopoietic Systems in Inflammatory Response • Regulation of Immune Response by Recombinant Lymphokines *in vitro* • Roles of Lymphokines *in vivo* • Concluding Remarks

Repligen IPA-300: The Protein A that can cut development time

Repligen provides ultrapure and immobilized rProtein A with complete documentation on file with the FDA and full support from our experienced staff of regulatory affairs specialists. This means that you lose less time substantiating your materials and complete your IND submission faster. Plus IPA-300 guarantees high binding and virtually no leakage to the toughest specifications in the industry. So for the consistent purity you need for single pass purification of therapeutic grade monoclonal antibodies, specify Repligen's IPA-300. Whether it's 2 milliliters or 2 liters, we'll ship in one business day. Cut through the paperwork. Call us today.*

Making authors toe the line

The idea that those who wish to contribute to the scientific literature should first satisfy preconditions sends shivers down the spine: are there compromises to be worked out?

DATABASES have come to stay and, like many other institutional innovations, have roused great passions. So much is plain from the manner in which the supporters of particular databanks advocate their virtues — with zeal, sometimes with blind zeal. Only a few weeks ago, in a nice illustration of that genre, one correspondent found himself declaring that "it is a simple matter to require that the author of a sequence paper provides an accession number . . . as a prerequisite to publication" (*Nature* **342**, 114; 1989). But is it?

So far as this journal is concerned, most passion centres on the decision that preconditions on the publication of research material are not simple. In particular, it has not hitherto been a precondition of the consideration of a manuscript for publication that nucleotide sequence data (if any) should first have been registered with one of the three branches (in Europe, the United States and Japan) of the international enterprise for compiling a coordinated nucleotide sequence databank. What follows is yet another explanation of what is plainly a contentious issue and of what some may even consider to be a remedy, this time evoked by the letter from Dr Lennart Philipson and his colleagues at Heidelberg (see page 849).

The first need, obscured in many of the arguments conducted in recent months, is that we should acknowledge the virtues of most databases, and of the nucleotide sequence databank in particular. It would be a great public service if there were a generally and uniformly available set of nucleotide sequences to which researchers could refer. Despite operational difficulties (many of them teething troubles) at the three centres, the service they provide is a good first approximation to a uniformly accessible sequence databank. There is good reason to expect that the arrangements now in place will be able to handle the much increased volume of data expected in the next few years. So far, it might be thought, so good. These are some of the reasons why this journal has, for several years, "urged" its authors to send their data to the sequence databanks. So why not go the whole hog, and make that a precondition?

This is not the arcane argument it may seem, but rather an issue of principle touching the relations between journals such as this and their contributors on the one hand and their readers on the other. It is not, of course, absurd, or an infringement of contributors' rights, that journals should require their contributors to satisfy certain preconditions — so many copies of a manuscript, typed in double-spacing, for example. Their justification is the mutual convenience of journals and their contributors that decisions should be reached quickly and that manuscripts chosen for publication should be as quickly processed. Tacitly, at least, such points are easily agreed.

Difficulties arise when contributors are asked to satisfy conditions that have nothing to do with the content of what they have to say, or the manner in which that is presented. Compliance with the wishes of the databanks is only one of the requirements that might be made of them. Why should not journals also demand, for example, that their contributors should have complied with the law? Would it not make for the tidier administration of regulations on the use of recombinant DNA techniques that the appropriate committees, if relevant, should have been notified and have given their approval? And the same, *mutatis mutandis*, for embryo research, the use of radioactive chemicals in the laboratory or the use of experimental animals in research? While they are at it, why should not journals also take on the administration of national legislation on secrecy?

Not all those who urge this journal to make mandatory the prior submission to databanks of nucleotide sequences would go so far as to applaud all possible innovations along these lines. An earlier correspondent (*Nature* **342**, 114; 1989) correctly argued that the interaction between journals and their contributors, usually anxious to appear in print, is a point at which pressure can be effectively applied. But that is all the more reason why journals, rightly fearful of being turned into instruments of law-enforcement, should resist it. And the only simple recipe for the avoidance of the consequences of prior conditions on publication is that there should be none.

Relations between journals and their readers are also important. The business of publication, which is an honourable and socially valuable business, is that of making information generally available. In principle, at least, all readers should be on an equal footing, with an equal chance to make what they can of what happens to be published. That is why this journal has, uniquely among journals with an interest in research, taken the trouble to print itself at three centres in world (so far). It remains a constant source of disappointment that the West Coast of the United States and Australia should be less quickly served than, say, New York or London.

Readers' appreciation of what they read depends, of course, on circumstances. People somehow in the swim are usually better placed to appreciate the full significance of what they find it interesting to read than those exiled to the sticks. Often it may be that a reader's understanding of a novel concept in a research article will fully flower only when he has talked it over with his or her colleagues, which is another kind of privilege. Most journals prudently acknowledge that these are circumstances they cannot change, much as they might wish to do so. But there are no circumstances in which a journal such as this, founded 120 years ago to bring the record of research to a wide audience, could fall in with the idea that its readers' appreciation of what they read will hang crucially on the accessibility of a databank in Heidelberg, Los Alamos or Mishima.

Accordingly, this journal has determined as follows: we shall continue (as at present) not to require of our contributors that they should have submitted their data (if in any way relevant) to the international databanks before submitting them for publication, but we shall threaten them that, if their articles appear in print and happen to be supported by nucleotide sequences, even if not intended to be published, we shall send those data off to Heidelberg or whichever other centre appears more congenial and also promises to make the data more generally available. We shall also make exactly the same data available to such of our readers who happen to telephone or to write. We shall do that without rancour, but shall aim to give the databanks a good run for their money. From time to time, we shall be willing to listen to people who have special secrets to hide.

This, then, is this journal's proposition: people with a nucleotide sequence to disclose should either disclose it or keep mum. They should not seek the best of both worlds, that in which they get credit for the sequence without saying what it is. Nor, for that matter, should they expect to be able to publish a sequence of nucleotides without being able to guess at what it means. Somewhere between, there must be a happy mean. Curiously, that boils down to an editorial function, not an issue of principle.

John Maddox

PLATE TECTONICS

Helium line in the Banda arc

Eli A. Silver

A LONG-STANDING enigma in geotectonics is just what melts to produce arc magmas in a subduction zone — where the cold, dense edge of oceanic lithosphere (crust and upper mantle) sinks into the deeper mantle. Can one recognize in the arc lavas differences in material entering the subduction zone? One approach to these questions is to use geochemical markers in the volcanics of island arcs, and a number of such techniques are known[1]. Results reported by Hilton and Craig on page 906 of this issue[2] show that helium isotope ratios, a useful geochemical marker, in island-arc basalts achieve a spatial resolution unequalled by other studies. Simultaneously, they identify remarkable processes occurring at the Sunda–Banda volcanic arc, a subduction zone in the Pacific ocean.

Earlier this year, Poreda and Craig[3] reported on a survey of circum-Pacific island arc studies of the ratios (R) of ^{3}He/^{4}He in arc materials relative to those (R_a) in air. (^{4}He is radiogenic and must be derived from contamination by continental crust.) They discovered that most of the circum-Pacific arcs have ratios R/R_a close to that expected from mid-ocean ridge basalts (MORBs), indicating that it is the mantle wedge above the slab, rather than the slab itself, that melts. The significant exception to this observation is at the Banda arc, where the ratios are much lower, indicating contamination from the subducting Australian continent. It is the data from the Sunda and Banda arcs that Hilton and Craig[2] now examine more closely. The authors demonstrate that the change from higher (MORB) ratios to lower (contaminated) values occurs over a narrow (200 km) zone. This transition corresponds with a well-defined zone of seismicity, which they interpret as faulting between the subducting Indian ocean and Australian continental lithospheres[4] (Fig. 2).

Gross differences in gravity, morphology, seismicity and volcanism between the Sunda and Banda arcs have long been known[5]. These differences have been best explained by the change in subduction from oceanic to continental crust. Hypothetical transform faults have been proposed to explain some surface geological variations, but these have not been substantiated by close scrutiny. The seismological studies[4] were the first to indicate a narrow zone of fault activity within the lower plate.

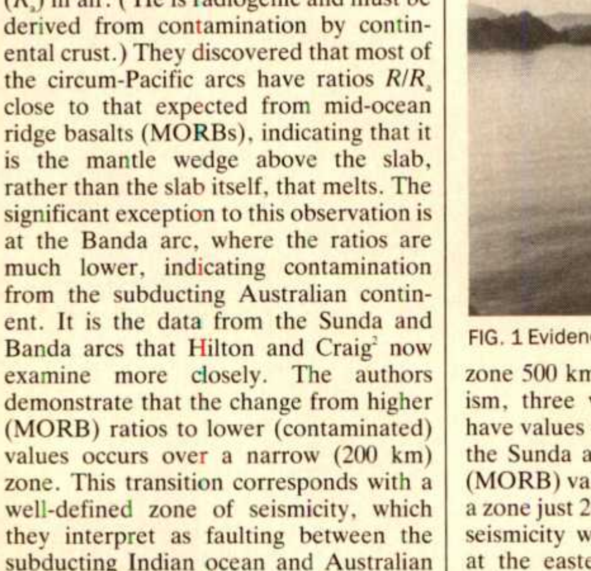

FIG. 2 Schematic diagram of transition between oceanic and continental lithosphere in Australian plate subducting beneath the Banda arc. Note source of arc magma in mantle wedge, generally about 100 km below the surface.

Hilton and Craig find that R/R_a ratios in the eastern Sunda arc, which includes Java, Bali, Sumbawa and western Flores, exceed those on eastern Flores and Pantar by factors of 2–4. Passing east of a zone 500 km wide without active volcanism, three volcanoes of the Banda arc have values 4–8 times lower than those of the Sunda arc. The transition from high (MORB) values to low values occurs over a zone just 200 km wide. The zone of high seismicity within the lower plate occurs at the eastern end of this geochemical transition.

Frank Lane Picture Agency

FIG. 1 Evidence of activity: Banda volcano on the eastern section of the Sunda – Banda arc.

It is reasonable to conclude from these studies that it is oceanic lithosphere that underlies the Sunda arc west of central Flores, and that contamination of the mantle wedge begins beneath eastern Flores. This initial zone of contamination is west of the zone of intense seismicity in the lower plate, so the latter may represent the transition from oceanic to continental lithosphere. The contaminants seen geochemically by Hilton and Craig could then indicate melting of continental margin sedimentary rocks, rather than the crustal rocks themselves.

But why the sharp transition? If the contamination is by sediments, would not the effect be gradual? The answer may lie in the structure of the western edge of the Australian continent. South-east of Sumba island, the lower plate has a fracture zone (an ancient transform fault) that divides the trench over a very narrow zone, about 25 km wide[6]. The fracture zone trends north-east, and its extension would place it very near the transition zone mapped geochemically by Hilton and Craig. East of the fracture zone, sediments several kilometres thick are entering the trench and a wide accretionary wedge is formed by scraping off the subducting trench sediments and accreting them onto the fore arc. West of the fracture the trench is nearly empty and the trench slope is steep, suggesting little accretion. If the surface structure shows so sharp a transition, might not the deeper mantle wedge be similarly affected? The results of Hilton and Craig imply that it is. They also show an antithetic relation between ^{87}Sr/^{86}Sr and R/R_a for the Sunda arc, but not for the Banda arc. This relationship supports the idea that two-component mixing of He and Sr is occurring over a large segment of the plate boundary, and has not been previously documented.

One might ask whether the Sunda–Banda arc structure is unique, or are there other examples? Poreda and Craig[3] measured somewhat lower values of R/R_a for Taiwan, a well-documented zone of subduction of continental crust. The ratio is slightly reduced in the eastern Aleutians, the Kuriles and Kamchatka, and Japan, which may be explained in part by thick sediment input to these trenches. No reduction is seen, however, in the Cascades arc, whose trench is thickly sedimented. No He data are yet available for the New Britain arc and the volcanoes north of Papua New Guinea, which lies in a somewhat different collisional regime to the Banda arc. The oceanic lithosphere beneath the Banda arc is continuous with the continent, and drags the continental rocks with it[4], whereas in the Papua New Guinea collision the oceanic lithosphere appears structurally separated from the continent[7]. That difference may explain the unique results of Hilton and Craig in the Banda arc — and it can be tested. □

CELL BIOLOGY

Mitosis and membranes

Graham Warren

WHEN cells divide, the chromosomes segregate and all other cellular components are partitioned between the daughter cells[1]. For most membrane compartments in animal cells the mechanism involves wholesale break-up; the cell, in effect, homogenizes the membranes yet does so in a manner which permits reassembly of the organelles. The pieces disperse randomly throughout the mitotic cell cytoplasm so that partitioning becomes a stochastic process dependent on the ability of the mother cell to divide itself into two daughters of equal size[2]. The molecular mechanism whereby membrane compartments are broken down is obscure, but the report by Tuomikoski *et al.* on page 942 of this issue[3] may provide a clue to what happens.

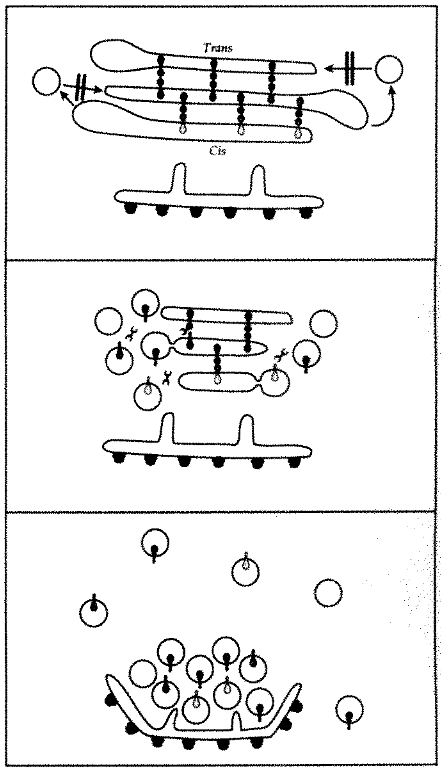
Morphological studies on organelle division go back to the beginning of this century[4], but progress was slow until the advent of electron microscopy and, more recently, immuno-electron microscopy. There are only single copies of the endoplasmic reticulum and Golgi apparatus in animal cells[5,6], so they have to be divided during mitosis. They are first broken into fragments and then vesiculated. The nuclear envelope always breaks down in animal cells, but the extent of vesiculation of the rest of the endoplasmic reticulum varies from cell to cell[7], perhaps because this organelle is present throughout the cell cytoplasm, and so does not need to be dispersed in order for partitioning to occur. In contrast, the Golgi apparatus, which has a restricted, juxtanuclear location[6], is completely vesiculated to ensure its dispersal and consequent partitioning[8].

Despite the apparent complexity of this process it is possible to suggest a very simple model for vesiculation[9] (see figure). The model demands separation of Golgi cisternae and cessation of vesicle fusion. Continued budding then converts the cisternae into free vesicles and clusters of vesicles which have been observed by immuno-electron microscopy[10,11]. Many lines of evidence point to an inhibition of membrane fusion during mitosis[9,12], but the evidence has, up to now, been indirect.

Tuomikoski *et al.*[3] have now shown that membrane fusion is inhibited in extracts from mitotic cells. Isolated endocytic vesicles were mixed in the presence of an energy source and frog cytosol, and fusion was shown to occur. When the cytosol was prepared from frog eggs arrested in metaphase II, fusion was inhibited. They also treated interphase cytosol with the sea-urchin homologue of $p34^{cdc2}$, the protein kinase of *cdc2*, which plays a key role in driving cells into the mitotic state[13]. This treated cytosol prevented fusion in a dose-dependent manner. Tuomikoski *et al.* have not, so far, shown that the effect of the extracts is reversible, but the absolute dependence of the reaction on $p34^{cdc2}$ is evidence in favour of their interpretation.

The link between endocytosis and intra-Golgi transport is provided by an *N*-ethylmaleimide-sensitive factor (NSF). This was known to be involved in the fusion of Golgi transport vesicles[14] and recent work has shown it to be involved in the fusion of endocytic vesicles[15]. Either NSF, or an associated protein of the fusion machinery, could therefore be the target for the inhibition during mitosis. But why inhibit the endocytic pathway? Is it simply the inevitable consequence of sharing the same fusion mechanism with an organelle that has to partition during mitosis? Or is it that endosomes are more elaborate and extensive than has so far been appreciated[16], and that they too have to be vesiculated and partitioned in the same way as the Golgi apparatus? It could be that most, if not all, intracellular compartments that communicate by way of vesicles are present in only one or a few copies and inhibition of membrane fusion provides the means of partitioning during mitosis.

The reason for having a single copy is not known, but it may be a device to unify the actions of an organelle. The resultant complex structures can then pose problems if the organelle needs to be moved to a new location in order to carry out a different function[17]. There is no reason why the partitioning mechanism should not work, during interphase, to facilitate such movement by way of vesicles. Mitosis would then represent the extreme when single-copy organelles are completely fragmented for partitioning.



Model for the vesiculation of the Golgi apparatus. Transported proteins move through the Golgi stack by way of vesicles which bud from the dilated rims and fuse with the next cisterna in the stack towards the *trans* side[20]. Transport occurs by bulk flow[21], which means that endogenous Golgi proteins such as the mannosidases and glycosyltransferases have to be prevented from entering the dilated rims. Lateral interactions might restrict their ability to act on glycoprotein substrates, so the simplest way to restrain them would be to link them to those proteins in the neighbouring cisterna which also need to be restrained. This would automatically generate the stack of cisternae which is the central feature of the Golgi apparatus. At the onset of mitosis transport vesicles would no longer be able to fuse (top panel) but budding would continue. At the same time, or shortly thereafter, the links between the cisternae would be broken allowing the endogenous Golgi proteins to move into the budding vesicles (middle panel). Continued budding would convert the cisternae into the vesicles (bottom panel) which are observed in metaphase animal cells[10]. Clusters of vesicles are also observed[11], though the material that binds them together has yet to be characterized.

Finally, one could ask why such a mechanism is used. Chromosomes, after all, use the mitotic spindle, so why is there not a more elaborate mechanism for segregating membrane-bound organelles? There are several possible reasons. First, unlike the chromosomes, there is no need to divide an organelle into two exactly equivalent pieces. If one daughter receives slightly more or less membrane, then mechanisms exist to correct the imbalance[18]. Second, the mechanism is straightforward in that it inhibits a pre-existing process, though additional modifications may be needed to ensure that the vesicles contain the information needed for reassembly[10]. Third, it is general because most, if not all, vesicle-mediated pathways share the same mechanism for fusing membranes, specificity being provided by other proteins[19]. Last, it is flexible. The vesicles generated are small and easily diffusible, so they should rapidly and randomly occupy the mitotic cell cytoplasm. This means that it does not matter what shape or size the cell is, so long as the cytokinetic mechanism divides it into two daughters of equal size[3]. The molecular mechanism underlying this membrane-partitioning process is of obvious interest and the report by Tuomikoski *et al.* is a step in the right direction. □

ECOLOGY

Answers that lie in the soil

Peter D. Moore

OUT of sight, out of mind, may be a convenient maxim for those with the inclinations of an ostrich. But it is hardly appropriate for ecologists concerned with estimating the productivity of the Earth's ecosystems, for much production occurs beneath the surface of the soil. The International Biological Programme (IBP) of the 1960s placed strong emphasis on the development of techniques for studying productivity and many data were accumulated which have subsequently been used in the assessment of the productive resources available for human support and, more recently, in developing a fuller picture of the Earth's carbon cycle. But many of these initial results are flawed by a failure to account adequately for the underground accumulation of carbon, and also for the continuous cycle of death and turnover of plant tissues above and below ground. Work by Raich and Nadelhoffer on forests[1] and by Long *et al.* on grasslands[2] now implies that some of the early results on this subject could be a serious under-estimate of the true values.

It would be wrong to suggest that the IBP pioneers were unaware of the problem of root productivity and turnover. Newbould[3] proposed that the ratio of below-ground biomass is proportional to that above ground and Newman[4] developed techniques for the measurement of the extent of plant roots within the soil by dissecting out sample soil volumes. Many field studies, however, neglected the subterranean part of the equation simply because of the difficulties involved in its measurement. Others estimated changes beneath the ground by subtracting the minimum from the maximum root biomass in a given year (Dahlman and Kucera in their studies of prairies[5], for example).

For forest ecosystems, there is considerable disagreement over the proportion of fixed carbon that is allocated to subterranean organs. Raich and Nadelhoffer[1] have collated and examined data derived from studies in a wide geographical range of forest ecosystems. They start by assuming steady-state conditions for their soil carbon cycle (which may itself be questionable) and derive an expression to show that the total carbon allocation to roots can be estimated by summing root detritus production and root respiration; this, in turn, is given by the soil respiration rate less the rate of above-ground litter production (which supplies soil heterotrophs with their additional source of carbon). Raich and Nadelhoffer conclude that there is a positive linear relationship between litter fall and carbon allocation to roots, but that, in proportional terms, relatively less of the fixed carbon is transported to roots in more productive forests. Ultimately, our knowledge of terrestrial carbon cycles will depend upon the precision with which such translocation can be predicted, and on more detailed evidence concerning the stability of the carbon reservoir in the soil.

Long *et al.*[2] present new results from a continuing UNEP study of four tropical grassland sites in Mexico, Kenya, Thailand and Brazil. They used 20 randomized sample plots, each 1.0m by 0.25m in size, which they cropped every month and determined the weight of living and dead tissues, both above and below ground. The root material was extracted from the soil cores using fine-mesh (2mm) sieves (no real advantage was found in using sieves of smaller aperture). They separated the live roots by staining with tetrazolium salts.

They were then able to calculate the turnover of plant matter, both above and below the soil surface, that is neglected in most standard procedures. In three of their sites they found that the traditional IBP methods had underestimated primary productivity by a factor of between two and five. On a global scale this means that there is substantially more productivity in the tropical grassland biome than has previously been realized.

These results have a bearing on both agricultural and carbon-cycling studies. In pastoralism, they imply that more energy is entering the ecosystem than had been thought. If a substantial amount of leaf material is dying and passing to detritivores, then one must conclude that the grassland is being under-used. Energy diverted to roots, however, is of no economic value to grazing animals. But even this aspect of carbon allocation has implications for global carbon-budget studies, for clearly there is a larger sink for carbon in the tropical grasslands than has previously been suspected, but only if some of the added carbon is accumulating in the soil. This does seem to be occurring in some of the grassland sites examined by Long *et al.* but much more effort needs to be expended on precise quantification of this build-up of organic matter. Equally important, the ploughing of grasslands for arable agriculture will inevitably result in the release of soil carbon back into the atmosphere. Perhaps the ostrich, with its head below the ground, was actually trying to tell us something. □

SYNTHETIC CHEMISTRY

Chemists get topological

Roland Pease

MOLECULAR LEGO is the term Fraser Stoddart and colleagues have coined to describe their approach to chemical synthesis. Yet this almost understates the ease with which the reagents assemble themselves to form the catenane — a linked-ring compound — depicted below (Fig. 1). Their new work[1] builds on both the host–guest chemistry for which Pederson, Cram and Lehn gained the Nobel prize, and the notion of topological isomers developed by Frisch and Wasserman[2].

Catenanes are characterized by the linking together of molecular rings without the intervention of covalent bonding. The importance of the new work is in the exploitation of non-covalent 'donor–acceptor' interactions that make the reagents act as templates for one another. In this way, the authors obtain a 70 per cent yield of the catenane product from a simple one-step reaction (stir reagents 2,3 and 4 — Fig. 2 — together in a solvent and leave to stand overnight); and that yield represents merely the red precipitate deposited and does not take into account any product still in solution. By comparison, other synthetic routes are both more complex and less efficient.

The key to the authors' success was the recognition of the non-covalent forces at work in host–guest complexes. They noted that the roles of electron donor (red) and acceptor (blue) are interchangeable in binding the supramolecular complexes 5 and 6 (Fig. 3). This reciprocity, they argued, could be used to stabilize a reaction intermediate in which an electron-donor guest ring (compound 4) would hold, vice-like, one limb of the u-shaped acceptor compound 2. Effectively, the two rings of the catenane — one initially incomplete — act mutually as templates for the reaction (Fig. 2), which is completed by the ring closure by moiety 3. The ingenuity deployed in the new work, the culmination of ten years of systematic study, is characteristic of studies in 'topological' chemistry.

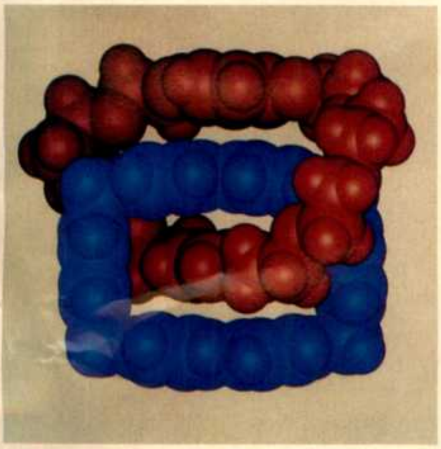

FIG. 1 Space-filling model of the [2] catenane (compound 1) synthesized by Stoddart and colleagues. Prepared on the basis of X-ray data by D.J. Williams and colleagues at Imperial College.

Previous attempts to synthesize catenanes have relied on the improbable threading of a large cyclic molecule onto a long single-strand molecule, on the remarkable topological properties of the Möbius strip, and on the ability of transition-metal ions to arrange organic ligand molecules in fixed orientations. The first method was also the first to work[3]. The two reagents are mixed in conditions that favour closure reactions of the linear molecule. In the rare event that ring closure occurs after the linear molecule has threaded the macrocycle, the product is [illegible] catenane that is topologically disti[illegible] from the main reaction product. Although only traces of catenane were made, their presence could be demonstrated by subtle use of deuterated reagents and analytical chemistry.

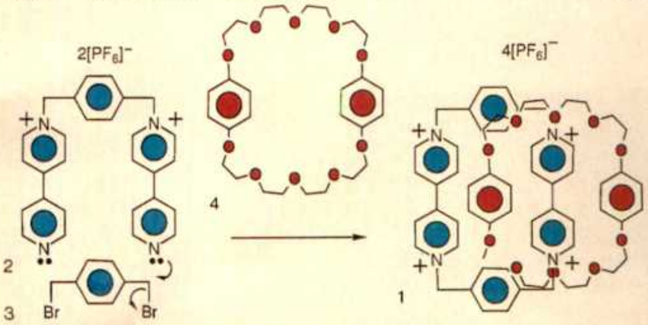

FIG. 2 Reaction scheme by which the [2] catenane (compound 1) is formed from a bispyridium salt $(2^{2+})\cdot 2PF^{2-}$, 1,4bis(bromomethyl)-benzene (3) and bisparaphenylene-34-crown-10 (4). The reaction was carried out at room temperature in dry acetonitrile (Blue, electron acceptor; red, electron donor.)

Cut a Möbius strip with two twists, and the result is a pair of rings with the same radius, but inextricably linked. The notion lends itself well to catenane synthesis, but the execution is not trivial. The problem is to find a double-stranded molecule with breakable crosslinks that is sufficiently flexible both to turn back on itself for ring closure, to form a loop and to twist twice on its axis. Nevertheless, a Möbius strip was successfully made (22 per cent yield) with a single twist in 1982 by D.M. Walba and colleagues[6]. The earlier attempt by Wasserman and colleagues[5,6] to synthesize the double-twist Möbius strip led only to trace quantities of catenane.

By far the most successful method to date is the use of transition-metal ions as templates for catenane synthesis. This approach, espoused by J.-P. Sauvage and colleagues[7], relies on the directionality of transition-metal–ligand bonds to dispose rigid reagent molecules in the correct arrangement for catenane synthesis. The ligands are either two half-rings or a half and a whole-ring which overlap and are completed by the addition of complementary half-rings. The final step in this synthetic route is to extract the strongly bound metal ion from the middle of the newly formed catenane without undoing the product. It turns out that the powerful ligand cyanide (CN^-) works admirably and yields of 50 per cent with respect to the starting materials are common. Not only have Sauvage and colleagues succeeded in making [2] catenanes (two interlocking rings) by this method, but also [3] catenanes and a trefoil knot — the simplest topological knot of a single strand.

The significance of the new work by Stoddart and colleagues is not restricted to the synthesis of an unusual molecule. The product is constructed from components that enter into charge-transfer interactions, the basis of conducting (and superconducting) organic crystals, and so has interesting electrical properties. Most notably, electrochemical experiments show that the reduction of the quadrupally charged, positive molecule (its acceptance of electrons) varies with the environment of the accepting units relative to the donor, the reduction potential depending on whether they are on the inside or outside of the donor macrocycle. Nuclear magnetic resonance experiments show that the molecule has two 'internal melting' points — a lower one at which the acceptor part (with the bipyridinium units, blue) starts to 'pirouette' around the axis defined by the interior $O-C_6H_4-O$ unit of the donor ring, and a higher one at which both rings become free to slip around one another.

Most of all, however, the work

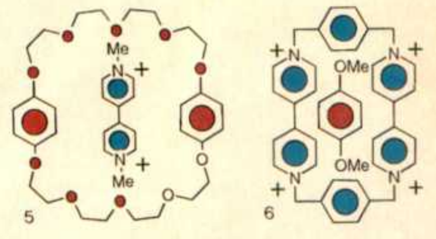

FIG. 3 Host–guest complexes of the paraquat di-cation (blue) with bisparaphenylene-34-crown-10 (red) (compound 5) and of cyclobis-(paraquat-*p*-phenylene) (blue) with 1,4-dimethoxybenzene (red) (compound 6) which were the models for the donor–acceptor forces stabilizing the intermediate in the synthesis of the [2] catenane (compound 1).

demonstrates the power of charge-transfer forces in allowing molecules to form their own template for chemical reactions. This effect lies at the very heart of the structure-directed methods of Stoddart and colleagues. If anything, Stoddart suggests there may even be an element of self-catalysis in the reaction — at least this is what seems to be indicated by the kinetics of the reaction. The authors are now working on a [3] catenane which, by all accounts, is easier to synthesize than its constituent parts. ☐

MAMMALIAN SEX DETERMINATION

Thumbs down for zinc finger?

Paul S. Burgoyne

TOWARDS the end of 1987 *Cell* published a paper by Page *et al.*[1] which convinced many (myself included) that the mammalian sex-determining gene, which directs the developing fetal gonad to form a testis, had been identified on the human Y chromosome. The gene in question encoded a 'zinc finger' protein (such proteins are believed to interact directly with DNA) and has been dubbed *ZFY* (zinc-finger Y); intriguingly, a very closely related gene, *ZFX*, was found on the X chromosome. I suspect I was not alone among those involved in trying to unravel the process of mammalian sex determination, who, on hearing this news, considered taking early retirement. Yet the months slipped by without the expected reports of *ZFY* expression in the developing fetal testis, although the equivalent mouse sequences were shown to be expressed in adult testes[2,3]. There then appeared a paper by Sinclair *et al.*[4] which revealed that *ZFY*-related sequences in marsupials were not on the Y chromosome. While some took refuge in the heresy that the Y chromosome might not be male-determining in marsupials, I abandoned for the moment thoughts of retirement to a cottage in the country. Now, two years after the discovery of *ZFY*, two papers in this issue of *Nature*[5,6] appear to exclude *ZFY*, and the mouse equivalent *Zfy*, from having a testis-determining role. (By convention, human gene labels are all capitals, whereas mouse gene labels have only the first letter as a capital. When referring to equivalent genes without respect to species I will use capitals in inverted commas — '*ZFY*', for example.)

Koopman *et al.*[5] (page 940) provide the long-awaited description of '*ZFY*' expression in the developing fetal testis. In the mouse there are two Y-chromosomal homologues of '*ZFY*', which are designated *Zfy-1* and *Zfy-2*; but because it had previously been shown that testes develop in the absence of *Zfy-2* (refs 3, 7), interest centred on *Zfy-1*. The initial results obtained by Koopman *et al.* seemed to strengthen the case that *Zfy-1* is the primary testis determinant: the first *Zfy-1* transcripts appear just before testis differentiation commences, they increase in abundance as testis differentiation ensues, and then decrease once testicular differentiation is established. It is to the authors' credit that they did not rush into print at this point. Instead, bearing in mind that *Zfy-1* (and *Zfy-2*) expression in adult testes appeared to be germ-cell dependent[5], they decided to see if *Zfy-1* expression occurred in fetal testes lacking germ cells. The answer was clear — no germ cells, no *Zfy-1* expression.

Now the pattern of *Zfy-1* expression can be viewed in a very different light: the appearance and increase in *Zfy-1* transcripts is correlated with the colonization of the developing gonad with germ cells, while the subsequent decrease in *Zfy-1* expression correlates with the cessation of germ-cell proliferation and dilution of these cells with the expanding somatic components of the test[illegible]t remains to be seen how far back in the [illegible]m-cell lineage *Zfy-1* expression occurs. Because testis determination is mediated by Y-chromosome expression in the Sertoli cell lineage[8], and can occur in the virtual absence of germ cells, one must accept the authors' conclusion that their observations "exclude both *Zfy-1* and *Zfy-2* as candidates for the mouse testis-determining gene".

What of '*ZFY*' in man? Since the paper by Page *et al.* appeared it has become clear that some XX men and perhaps all XX true hermaphrodites (that is, individuals with ovarian and testicular tissue) lack *ZFY*[9], and that, in some instances, *ZFY*-negative XX males and hermaphrodites can occur in the same families. For reasons I shall come to later, I became convinced that these familial XX males and hermaphrodites could best be explained if the primary testis-determining gene was distinct from *ZFY* and lay very close to the pseudoautosomal boundary. I shall refer to this primary testis-determining gene as *TDY* (*Tdy* in the mouse). If the original 'mutation' giving rise to these familial cases of XX sex-reversal involved an X–Y interchange, then they should be positive for Y-specific sequences adjacent to the pseudoautosomal boundary.

Palmer *et al.*[6] (page 937) have examined 14 males or hermaphrodites who lacked *ZFY*; three of the males and one of the hermaphrodites did indeed carry Y-specific pseudoautosomal boundary sequences. Although the remainder lacked the boundary, they could have had small insertions that include *TDY*, rather than having mutations "elsewhere in the testis-determination pathway", as Palmer *et al.* suggest. The authors conclude that "these results lead to the strong prediction that a gene involved in sex determination lies close to or even spans the pseudoautosomal boundary". The hunt is now on!

So, do we now conclude that Page *et al.*[1] were wrong and leave it at that? I think not, because it would leave too many loose ends. Palmer *et al.* suggest that the only discrepancy between their findings and Page's lies in the latter's conclusion that at least part of the testis-determining gene must fall within the region of the Y chromosome missing in 'XY' female WHT1013. This 'XY' female in fact carried a reciprocal translocation between the Y chromosome and chromosome 22 (Fig. 1). Presumably loss of the region of the Y chromosome that includes *ZFY* occurred in conjunction with this reciprocal exchange. The crucial question is whether this individual is female because of the deletion of *ZFY*, or because of some other effect of the translocation. Palmer *et al.* favour the second explanation; they suggest that the testis-determining gene (located near the pseudoautosomal boundary) could have been inactivated through a 'position effect' because this

FIG. 1 The deduced arrangement of Y-chromosomal material (shaded) in the 'XY' [46,X,t(Y;22)] female WHT1013 of Page *et al.* (see ref. 1). Note that the Y pseudoautosomal region and, according to Palmer *et al.*[6], the testis-determining gene (*TDY*), are on the 22^Y chromosome. *ZFY* has been lost during the exchange.

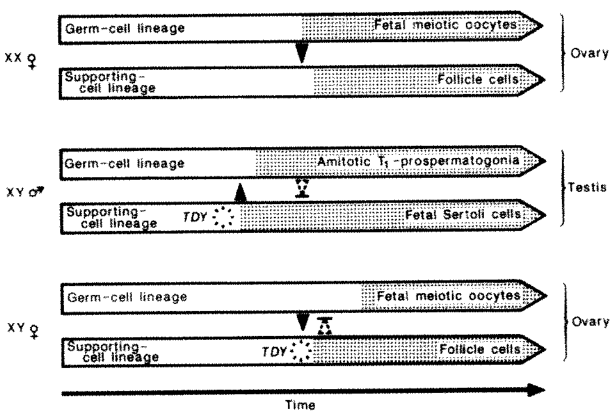

FIG. 2 A model for mammalian sex-determination and XY sex-reversal. In the 'default' pathway to ovarian development (top panel), the germ-cell lineage, as a normal consequence of its differentiation, produces a diffusible ovary determinant which commits the somatic supporting cell lineage to form follicle cells. In the diagram the production of the ovary determinant is arbitrarily shown to occur around the time the germ cells enter meiosis. In the male (second panel) *TDY* directs the somatic supporting-cell lineage to form fetal Sertoli cells. It is envisaged that these cells retain the capacity to respond to the ovary determinant. However, the fetal Sertoli cells carry out a 'pre-emptive strike' against the germ cells, committing them to the male pathway as T_1-prospermatogonia, thereby blocking the production of the ovary determinant. In the text it is suggested that one route to XY sex-reversal is via a developmental delay in the gonadal soma, so that the germ-cell lineage produces the ovary determinant *before* the pre-emptive strike from the supporting-cell lineage can occur (lower panel). The involvement of altered growth rates in sex-reversal has been argued by Mittwoch[18], although with a different mechanism to that illustrated here.

part of the Y is now attached to chromosome 22. In what follows I will try to argue a case for the alternative possibility: that deletion of *ZFY* was, as Page *et al.* supposed, the cause of the sex reversal.

In arguing the case for a role for '*ZFY*' in sex determination in man (but not in the mouse), my starting point is the striking difference between the two species in '*ZF*' gene expression in somatic tissues. In humans *ZFX* and *ZFY* are ubiquitously expressed, and *ZFX* is not dosage-compensated by X-chromosome inactivation[10]. Thus the normal expressed '*ZF*' gene dose is two – (2 *ZFX*, or 1 *ZFX* + 1 *ZFY*). In mice, only *Zfx* is expressed in somatic tissues, and it is almost certainly dosage-compensated by X-chromosome inactivation, so that XX cells have one active copy of the gene (R. Lovell-Badge, personal communication). This dosage compensation makes sense because it equalizes the '*ZF*' dosage in males and females, the normal expressed '*ZF*' dose in mice being 1 *Zfx*. Consider now that mouse XO individuals show only a mild retardation early in embryonic life[11], and have normal prenatal and postnatal viability. In marked contrast, human XO individuals are so seriously affected that more than 95 per cent of those conceived do not survive to term, and those that do are subject to the range of defects which constitute Turner's syndrome.

It does not require a major leap of imagination to attribute the severe developmental abnormalities in human XO individuals to their deficiency in '*ZF*' gene dosage, and to attribute the anti-Turner effect of the Y (men have one X chromosome but do not have Turner's syndrome) to the observed expression of *ZFY* in somatic tissues. Indeed, this anti-Turner effect of the Y maps to the same region as *ZFY*[12]. In mice, where the norm is one expressed dose of *Zfx*, XO individuals will only be at a disadvantage in the early embryonic period, when, before X-inactivation, XX embryos could be expressing two doses of *Zfx*.

I now want to introduce a concept relating to XY sex-reversal which will be crucial in the arguments that follow. The obvious route to XY sex-reversal is through loss or inactivation of the testis-determining gene '*TDY*', and there is tantalizing mention of just such a mouse mutant at the end of the paper by Koopman *et al.*[5]. But an alternative route, for which there is convincing evidence in the mouse[13,14], is one where there is a 'timing mismatch' between the testis-determination process and the ovary-determination process, such that '*TDY*' fails to pre-empt ovarian development. My own working hypothesis for how this might operate is explained in Fig. 2. This hypothesis predicts that if the development of the XY gonadal soma is slowed relative to the germinal component, then an ovary can develop. Although '*TDY*' is present it 'misses the boat'.

There are some human pedigrees in which the pattern of inheritance of XY sex-reversal clearly implicates an X-linked mutation. Paradoxically, in the mouse where the extensive breeding of X-chromosome-marked stocks should easily detect such a mutation, no X-linked cases of XY sex-reversal have been identified. A resolution to this paradox can be provided by bringing together the arguments presented in the preceding two paragraphs. If a double-expressed '*ZF*' dose is needed for normal human somatic development, and retardation of the somatic compartment of an XY fetal gonad can lead to sex-reversal, then a mutation that interfered with human *ZFX* expression could result in XY sex-reversal by the 'timing mismatch' route. In the mouse, where a single expressed *Zfx* dose is the norm, interference with *Zfx* expression would be expected to be lethal in early embryogenesis, thus precluding this as a route to XY sex-reversal.

It is now only a small step to explaining the sex-reversal of Page's *ZFY*-negative 'XY' female WHT1013. In man, *ZFY* contributes to the expressed '*ZF*' dose in somatic tissues, so deletion of *ZFY* could result in retardation of the gonadal soma, and thus once again lead to XY sex-reversal by the 'timing mismatch' route.

Having concluded that a double '*ZF*' dose is necessary in man to ensure that *TDY* can pre-empt the ovarian pathway, we can now return to the familial cases of *ZFY*-negative XX males and hermaphrodites. I would argue that testicular tissue develops in these individuals because they not only have *TDY* (located close to the pseudoautosomal boundary) but they also have a double 'ZF' dose (2 *ZFX*). These familial cases raise two further questions, however: how can the trait be transmitted when XX males are always sterile, and why are there so many hermaphrodites?

A lesson we have learned from mice is that hermaphroditism can only be achieved by walking a developmental tightrope: the system is strongly canalized to give either ovaries or testes. Indeed, hermaphrodites frequently have an ovary on one side and a testis on the other, rather than ovotestes. Where a particular

FIG. 3 Proposed scheme for the inheritance of *TDY*-positive, *ZFY*-negative XX sex-reversal. It is suggested (see text) that XX, *TDY*$^+$ individuals can develop not only as sterile males and hermaphrodites, but also occasionally as fertile females, the latter holding the key to the transmission of the trait.

genotype does produce some hermaphrodites, genotypically identical males and females are also produced. Thus I would argue that familial transmission of XX sex-reversal occurs in the first instance through a *TDY*-positive female. In the next generation transmission is possible through XY male carriers (Fig. 3). But if this hypothesis is correct, we have to explain not only how you can get *TDY*-positive hermaphrodites, but also how *TDY*-positive females arise.

I suppose that by analogy with T16/X*Sxr* mice, which can develop as females, males and hermaphrodites[15,16], a spreading of X-inactivation into *TDY* could be invoked as the cause of the variation in sexual phenotype (in these mice, the X chromosome bearing the sex-reversing factor *Sxr* is held in the inactive condition by a translocation between the X chromosome and chromosome 16). The fact that *ZFY*-positive sex-reversed XX individuals are invariably male would then have to be attributed to the interposition of more Y chromosomal material between *TDY* and the X chromosome in these cases. An alternative explanation for the occurrence of *TDY*-positive females, which I find attractive, brings us back once more to *ZFY*. Although I have argued that *ZFY* and *ZFX* are functionally interchangeable in the soma, the proteins they encode are not quite identical. It is therefore possible that *ZFY* could exert a stronger effect than *ZFX*. If so, 1 *ZFX* + 1 *ZFY* could be necessary to ensure that *TDY* pre-empts the ovarian pathway, 2 *ZFX* representing a borderline dose in this respect so that *TDY* sometimes 'misses the boat'. The *ZFY*-positive XX individuals should always be male because, in addition to *TDY*, they have overkill in terms of '*ZF*' dosage (2 *ZFX* + 1 *ZFY*).

So far we have only viewed '*ZFY*' as a '*ZFX*' substitute. What then is the evidence for '*ZFY*' having any truly male-specific role? The high levels of '*ZFY*' expression in adult testes are certainly a strong indication of a male-specific function, and I have suggested elsewhere[17] that *Zfy* (principally *Zfy-2*) could be the mouse spermatogenesis gene *Spy*; *Spy* is required from about one week after birth for the normal proliferation and survival of spermatogonia. The evidence that *Zfy-1* is expressed in the germ cells of fetal XY mouse gonads does not necessarily imply a male-specific role for the Y in the germ line at this earlier stage. XO germ cells in XO/XY mosaics, despite lacking *Zfy-1* and *Zfy-2*, certainly form fetal prospermatogonia, and go on to form definitive spermatogonia post-natally. Perhaps *Zfy-1* in the fetal XY gonad is once again just standing in for *Zfx*. After all, both X chromosomes become active in the germ line of females around this time.

The results now published by Koopman *et al.*[5] and Palmer *et al.*[6] apparently exclude '*ZFY*' from being the testis-determining gene. I have argued t[illegible]FY in man, could, together with *ZFX*, be necessary to ensure that the testis-determining gene can pre-empt ovarian development. If this is correct, then the human Y-chromosomal 'testis-determining factor' *TDF* can be equated with *TDY* + *ZFY*.

If the views presented here prove to have any validity, then many people who have shared their ideas with me deserve credit. I would especially acknowledge the contributions of Robin Lovell-Badge and Jean Weissenbach. If this all proves to be nonsense, there is always that cottage in the country. □

VOLCANO PREDICTION

Measures of little gravity

Robert I. Tilling

THE measurement and mapping of anomalies in the Earth's gravity field constitute a powerful geophysical technique for studying crustal structure. The detection of minute changes in the gravity field preceding volcanic eruptions is an aspect of especial interest. The causal link between changes and eruption is often hard to identify unambiguously, but Rymer and Brown, reporting on page 902 of this issue[1], suggest that a mechanism is discernible for microgravity changes preceding the eruption last spring at Poás Volcano in Costa Rica. The variations reflect, they argue, the shallow intrusion of magma beneath the volcano's summit crater lake and its subsequent cooling and vesiculation, and the evaporation of lake water. More importantly, the authors imply that the trend of gravity increase that started in 1985 was a precursor of the explosive eruption in April–May this year.

Although gravity measurements were attempted in the late 1930s at Mont Pelée (Martinique, Lesser Antilles) in an effort to identify a precursory phenomenon, it was not until the development of high-precision gravity meters in the 1950s that successful studies of temporal variations could be made[2]. With modern high-sensitivity instruments and well-designed field-measurement techniques, gravity changes at a volcano can be measured to a precision of10^{-5} (10 microgal) or better[3-6]. After correction for Earth tides and instrumental factors, measurable variations in gravity can be attributed to displacements of the observation point resulting from deformation produced by the intrusion or withdrawal of subsurface magma and the redistribution of mass in the volcanic plumbing system.

Fortunately, the free-air effect of elevation change on the observed gravity can be calculated if the elevation is also monitored. Alternatively, it can be estimated indirectly by periodic reoccupation of geodetic networks deployed to monitor ground deformation at volcanoes. Once the elevation changes are allowed for, the gravity residuals, if any, can be interpreted in terms of various models of mass redistribution affecting the volcanic system[2,3-7]: surface and subsurface movement of magma, particularly the filling and draining of a near-surface magma reservoir; changes in density of the magma bodies, through degassing, vesiculation (cavitation), cooling and contraction, or hydrothermal alteration; and changes in the surface and subsurface hydrological and geothermal regimes.

Poás is one of several active volcanoes in Costa Rica. Virtually all of its historical eruptions have occurred at a highly acid, hot crater lake that lies at its summit. Accordingly, the activity of the volcano — the boiling of lake water and its eruption in geysers, the ejection of mud plumes, explosive, steam-driven (or phreatic) eruptions, and (less commonly) the ejection of pyroclastic sulphur and lava eruptions — reflects the complex interaction, at relatively shallow depth, between the crater lake, the subsurface hydrothermal system, and the magma body[8]. In recent decades, several Costa Rican research groups, in cooperation with earth scientists from elsewhere, have initiated or augmented seismic, geodetic and other studies at Poás. Rymer and Brown's measurements of gravity changes since 1979 contribute to the growing body of knowledge about the behaviour of Poás.

The gravity changes in the period 1979–85 (less than 120 microgal) show no particular trend, permitting the somewhat speculative interpretation that the variations result largely from 'cyclical' changes in density of the underlying magma related to degree of vesiculation[1,7]. Since 1985, there has been a trend of increasing gravity (by up to 400 microgal) at some of the gravity stations, which Rymer and Brown attribute to a shallow magma intrusion which perturbed the hydrothermal activity of the crater lake. Ultimately, they suggest, this culminated in the vigorous phreatic explosions of April–May 1989. This interpretation, and the supporting data for it, are clearly summarized in figures 1-3 of their paper[1].

Unfortunately, as Rymer and Brown acknowledge, the elevation monitoring at Poás Volcano was poor before 1987. The authors argue that elevation changes before 1987 were probably not significant. But without the data, and the consequent allowances in interpreting the gravity data, their model, although certainly plausible, cannot be substantiated.

The elevation controls since 1987 need to be considered in the context of other monitoring data from Poás, one of the best-observed volcanoes in Latin America. In addition to continuous seismic monitoring, various geodetic (electronic tiltmeter, precise-level line, and ground-tilt arrays), thermal and geochemical measurements are made periodically at Poás[9]. But such data largely remain unpublished. The limited data that have been reported through the Scientific Event Alert Network (Smithsonian Institution, Washington DC) suggest that measurable changes took place in the state of the volcano leading to the April–May 1989 explosions. For example the summit was sharply inflated during June–August 1988, deflation following in the next five months; seismicity increased by an order of magnitude after January 1989; and there was a shift in the site of vigorous thermal activity in March 1989, suggesting[10] that "magma is rising below the lake . . . could lead to an eruptive event". These observations need to be incorporated with Rymer and Brown's to strengthen or modify their interpretation.

Can microgravity be used for predicting volcanic eruptions? For now, the strict answer has to be "no": a 'prediction' is generally defined[11] as "a comparatively precise statement of the time, place, and ideally, the nature and size of impending activity" made before the activity occurs. Although the microgravity studies at Poás and other well-studied volcanoes clearly show that the method is capable of detecting and monitoring magma movement, they do not yet meet the full rigour of this definition. I would fully concur with Rymer and Brown[1] that microgravity surveys have "considerable potential for understanding magma chamber dynamics and eruptive precursors, *especially when* [my italics] combined with accurate height control", if the words *only if* were substituted for *especially when*.

Lastly, microgravity surveys require the operator to be on site — not necessarily a felicitous situation for the operator given the explosive nature of the activity at many volcanoes. Techniques suited to remote and continuous monitoring seem preferable for recording precursory processes immediately before an eruption. Nonetheless, experience indicates that volcano monitoring is best achieved by integrating many approaches, among which microgravity measurements should definitely be included. ☐

IMMUNOLOGY

Making antigen-receptor genes

Gary Rathbun, Frederick W. Alt and George D. Yancopoulos

IN a paper that appears on page 934 of this issue[1], and in a report in *Cell*[2], two groups describe the cloning of genes that encode proteins that may play critical roles in the assembly of antigen-receptor variable-region genes. The enormous diversity of antigen-binding specificities expressed by B and T cells of the immune system depends upon a strictly regulated, site-specific genomic recombination process. This recombination process assembles component gene segments (*V* for variable, *D* for diversity and *J* for joining) into variable-region genes that encode the antigen-binding portions of the various B- and T-cell antigen receptors (Ig and TCR, respectively). *V*-(*D*)-*J* recombinase activity has been assayed in cells through the use of introduced recombination substrates (containing unrearranged *V*, *D* or *J* segments flanking selectable marker genes). Such experiments showed that a single, shared *V*-(*D*)-*J* recombinase activity rearranges all three Ig and the four known TCR antigen-receptor variable-region gene loci; the recombinase is targeted to the respective gene coding segments by similar recombination recognition sequences (RS) that flank all Ig and TCR *V*, *D* and *J* coding segments. In addition, recombinase activity was generally found only in the early stages of B- and T-cell development and not in non-lymphoid cells (for review see refs 3 and 4). Based on this information, several strategies have been employed in the attempt to isolate the genes and/or the protein products involved in *V*-(*D*)-*J* recombination. These have included isolation of genes specifically expressed in early B- and T-lineage cells, isolation of genes encoding RS sequence-binding proteins, and isolation of genes that confer a recombinogenic phenotype on non-lymphoid cells.

Recombination recognition sequences consist of a palindromic heptanucleotide sequence and an A/T-rich nonanucleotide sequence separated by a spacer of either 12 or 23 base pairs. *V*-(*D*)-*J* recombinase activity apparently only efficiently recognizes and joins a gene segment flanked by an RS with a 12-base pair spacer to a segment flanked by an RS with a 23-base pair spacer (12/23 rule). Complete understanding of the precise mechanism of *V*-(*D*)-*J* joining awaits the definition of the enzymatic machinery that carries out the process, although general aspects of this mechanism have been elucidated[3,4]. The various activities required include recognition of the RS sequences, site-specific endonucleolytic cleavage between these RS sequences and the adjacent gene segments, potential nucleotide addition and removal activities at the ends of the severed segments (which increases coding diversity at the junctions between the segments), and ligation of the gene segments involved[3]. Apart from the enzyme terminal deoxynucleotidyl transferase, thought to be involved in adding extra nucleotides during junction formation and not to be essential for *V*-(*D*)-*J* joining, none of the component(s) involved in *V*-(*D*)-*J* recombination has been isolated.

Several groups have previously reported proteins that bind specifically to the heptamer or nonamer of the RS sequences[5,6]. Matsunami *et al.*[1] now describe the purification from nuclear extracts of a precursor B-cell line of a protein of relative molecular mass 60,000 (60k) that binds to an RS, and the isolation of a complementary cDNA clone (*RBP-2*) based on the partial amino-acid sequence of this protein. The protein encoded by this cDNA does not have extensive overall homology with any known proteins, but displays an intriguing homology to a 40-residue region that is conserved among a subset of site-specific recombinase (the integrase family) in prokaryotes and the Flp recombinase in yeast. The authors suggest that this 40-residue region may represent the catalytic domain of *V*-(*D*)-*J* recombinase, with other regions of the proteins conferring binding specificity. But elucidation of the relationship of *RBP-2* to *V*-(*D*)-*J* recombinase activity awaits further information (see later).

Schatz, Oettinger and Baltimore[2] have isolated a 'recombination activating gene' (*RAG-1*) through its ability to activate *V*-(*D*)-*J* recombination when introduced into NIH3T3 fibroblasts[7]. The fibroblasts contained a recombination substrate that conferred drug resistance only when specifically rearranged by *V*-(*D*)-*J* recombinase; oligonucleotide-tagging of transfected genomic DNA fragments allowed for the isolation of the activating gene. Significantly, expression of *RAG-1* precisely correlates with expected (or measured) early lymphoid specificity of *V*-(*D*)-*J* recombinase activity in cell lines and normal tissues. The *RAG-1* gene encodes a 119k protein that is highly conserved between species. The only suggestive homology of *RAG-1* with known proteins was to the DNA-binding domain of the glucocorticoid receptor. Although these authors favour the idea that *RAG-1* encodes all or part of the *V*-(*D*)-*J* recombinase, they do not rule out the equally interesting possibility that *RAG-1* acts as a regulatory molecule that activates the *V*-(*D*)-*J* recombinase gene or protein.

Fibroblasts that express a transfected *RAG-1* gene do not express any of several other lymphoid-specific molecules, suggesting that either *RAG-1* is a very specific regulator of *V*-(*D*)-*J* recombinase or that it is a direct participant in the actual recombination process. In the second case, *RAG-1* would either act alone or recruit more ubiquitous accessory factors present at least in the NIH3T3 cell line used; there is a precedent for this, in that accessory factors are known to exist in prokaryotic systems[8]. Various analyses have indicated that the severe combined immunodeficient (SCID) mouse has a defect that impairs the final stages of *V*-(*D*)-*J* recombination[3,4,9]. The SCID mutation maps to chromosome 16, whereas *RAG-1* apparently maps to a different chromosome. Thus the SCID mutation may affect a gene normally activated by *RAG-1* (if it is an activator) or a gene encoding an accessory factor recruited by *RAG-1* (if *RAG-1* is a major *V*-(*D*)-*J* recombinase component). In support of the second possibility, recent evidence suggests that the SCID gene may encode a protein more generally involved in DNA repair[10].

Although a transfected *RAG-1* gene activates *V*-(*D*)-*J* recombination in a cell line that does not normally undergo rearrangement, it does so very inefficiently. This finding could be explained in several ways. The most mundane is that the current *RAG-1* clone carries a debilitating lesion. A more interesting explanation is that there is a lymphoid-specific component of *V*-(*D*)-*J* recombinase in addition to *RAG-1*, and that component must also be expressed for complete recombination activity to occur. If the second possibility were true, it would point to the presence of another gene encoding an activity that would complement *RAG-1* to yield higher efficiencies in the *V*-(*D*)-*J* recombination assay — the *RBP-2* gene will be an obvious candidate to test in this context.

There are many other important questions that should readily be answered with the reagents at hand. It is essential to know whether *RBP-2* actually has recombinase activity and whether *RBP-2* gene expression and/or *RBP-2* binding activity is restricted to cells with known *V*-(*D*)-*J* recombinase activity. With respect to the various possibilities outlined here, does *RAG-1* activate expression of *RBP-2* (which may then act alone or together with other factors to mediate *V*-(*D*)-*J* recombination), or does *RBP-2* act synergistically with *RAG-1* to carry out recombination? If either or both *RAG-1* and *RBP-2* are components of *V*-(*D*)-*J* recombinase, then an *in vitro* system to study *V*-(*D*)-*J* recombination may finally be feasible. Such a system should allow complete elucidation of the mechanism of the *V*-(*D*)-*J* recombination process (for example, the nature of the 12/23 joining restriction). But it remains to be seen whether the availability of *V*-(*D*)-*J* recombinase genes and gene products will provide a system better to address the nature of the mechanisms that direct a common *V*-(*D*)-*J* recombinase to join different Ig and TCR loci (with similar or identical RS sequence) in a stage- and lineage-specific manner[3]. Finally, it will be important to determine how the *RAG-1* and *RBP-2* genes evolved and whether these sequences will allow identification of related, but as yet undescribed, proteins that could act in other recombinational processes. ☐

DAEDALUS

Lifeless prose

JUST as the calculator has produced its own brand of innumeracy, so the word processor is generating its own style of illiteracy. Its speed and ease, says Daedalus, are filling books, papers, journals and commercial literature with increasingly muddled English.

Spelling checkers, and even the more recent grammar-sensitive 'style checkers', only give the muddle a little extra polish. The reader is still left with the thankless task of trying to make sense of it all. So DREADCO programmers are developing a novel word program. It tries to deduce what, if anything, the author has to say, and then nags him into saying it clearly.

DREADCO's 'Literary Critic' seeks clarification of every sentence typed. "You haven't mentioned protons before", it might remark; or "You said the opposite in line 157", "Is 'aromatic' the smell or the chemical?", and for real puzzles, "Do you really mean that?".

These seemingly intelligent interjections stem from the program's attempt to find a 'logical tree' behind the growing narrative. Like other conversational programs, the Literary Critic has a big dictionary of words and synonyms classified by type — animals, locations and so on — and connected by their most likely relationships. Once it has decided what the text is 'about', it queries every apparently new or discordant topic, and amends its dictionary accordingly. It marks occurrences with their stated sequence in time, keeps tabs on the 'cast' of concepts or characters being discussed, and asks further questions when ambiguities or inconsistencies seem to occur. Where logically necessary, it generates new linking text, and tries to arrange the whole assembly of statements into their neatest logical tree. Such is the power of persistent Socratic questioning, says Daedalus, that the most complex and rambling chain of remarks should soon be clarified into a coherent story. It won't be immortal prose, but it should be a grammatical and effective piece of writing.

Self-conscious stylists will greatly resent the Literary Critic with its endless silly questions. But the children and students of the electronic age will simply accept it as an effortless and automatic way of working out what they want to say, and then saying it in a straightforward manner. And many humbler folk, with fascinating ideas and personal stories to tell if they only dared to sit down and write them out, will be grateful for its tireless and patient tuition. It will help policemen and insurance assessors to extract sensible evidence from befuddled witnesses, tease effective instructions out of skilled but inarticulate craftsmen, and trick unwary criminals into much completer confessions than they had intended.

David Jones

molecular-genetic information is usually introduced at this point, followed by the clinical aspects, including at least the principles of treatment. The general sections have been considerably expanded to take account of the needs of students at all levels, as well as of scientists and clinicians working in the field, to be conversant with many areas of molecular biology, cell biology, immunology, major chromosomal disorders and cytogenetics.

The field covered by the book has expanded greatly as more single-enzyme defects have been defined and as the genetic heterogeniety of those already known has been documented. Heterogeniety within the inborn errors of metabolism also stems from the fact that the specific mutation operates against different backgrounds of polygenic influences and environmental factors in different individuals. There are also genetic factors contributing to diseases that are not inherited in a simple mendelian manner but that operate through biochemical mechanisms. These considerations indicate further expansion in the future and emphasize the masterly degree of compression which has been achieved in this new edition.

Appropriately, most writers on inherited single-enzyme defects and human biochemical variation, including the present editors, look back to Sir Archibald Garrod's Croonian lecture "Inborn Errors of Metabolism", delivered before the Royal College of Physicians of London in June 1908, as a landmark in the development of their subject. The present growing confluence of the biomedical sciences, providing a substratum for our wider understanding of disease, but defying the old categorizations such as biochemistry, molecular biology, genetics and pathology, was perhaps foreshadowed in Garrod's essay "The Inborn Factors in Disease", published in 1931. In this undeservedly little-known work, Garrod explored the concept of diathesis (a condition of the body which renders it liable to certain diseases) and tried to discern some elements of the scientific basis for it.

As the last decade of the twentieth century dawns, it seems reasonable to suggest that macromolecular structure interactions and aberrations (macromolecular pathology) are the scientific bases for diatheses, and a type of explanation towards which Garrod was groping more than 60 years ago. The sixth edition of *The Metabolic Basis of Inherited Disease* points forward in this direction and hence towards a wider brief for future editions. ☐

The practice of theory

M. B. Usher

Mathematical Biology. By J. D. Murray. *Springer-Verlag: 1989. Pp. 767. DM89, £35, $59.*

In a minority of books, the author strikes the 'right' note and the reader says something like "I couldn't put it down". Most books do not fall into this category even when the author has something important to say. Other books, usually works of reference, simply defy reading because of the sheer magnitude of the task. Murray's book falls into this category. That is not to belittle the book in any way, as it is clearly a *magnum opus* on the application of mathematics in biology. Nevertheless, I have dipped into it rather than reading it from cover to cover, omitting some sections and rereading others. In the areas of biology that interest me, I have discovered here some fascinating analyses.

The book is divided into 20 chapters, starting with ecology (growth of single-species populations) and ending with epidemiology (here meaning the geographical spread of diseases, although the definition could also include the spread of invasive species). The beginning and end do, however, obscure the pathway that Murray takes from one to the other. Perhaps it could be said that the continuous growth of single-species populations produces the simplest model ($dN/dt \propto N$) and hence is the best starting point. Murray then expands this simple model into discrete population models for single species and into both continuous and discrete models for interacting populations. To me, the surprising feature of this section of the book is that it is set in a calculus mould; Murray does not include the equivalent formulation of discrete models as Leslie matrices and the subsequent developments of difference equations.

Murray then moves from populations to reaction kinetics, which are introduced with a detailed analysis of Michaelis–Menten theory. Biological oscillators, feedback control mechanisms and the Hodgkin–Huxley theory of nerve membranes serve as an introduction to a section on the many facets of oscillators. As might be expected, this section includes a discussion of limit cycles and of local/global stability, but it also includes topics such as unexpected 'black holes' in this area of biology.

Oscillator-generated wave phenomena are used to introduce the study of biological waves; together with the concept of reaction–diffusion the book then explodes into a bewildering array of applications, cutting right across the traditional divisions in biology. Models of waves are used to explore the spread and control of insect populations, the calcium-activated waves across the eggs of amphibia and a teleost fish, and patterning in cultures of slime mould. I found the analyses in chapter 15 particularly fascinating because the reaction–diffusion mechanisms are used to explore mammalian coat patterns (hence the spotted leopard on the cover of the book) and, more excitingly I felt, the patterns on butterfly wings. Although some, perhaps most, patterns of lepidopteran wings can be modelled on the basis of a diffusing morphogen, it is salutory that a series of butterfly wing patterns is illustrated for which models have yet to be developed. Is this a project for a PhD student?

Pattern is not manifest solely in the morphological patterns of mammals, insects or marine algae, but also in relation to neurobiology and development. Although in chapter 16 Murray largely concentrates on drug-induced hallucinations, he also explains mathematically how sufferers of migraine headaches see geometrical patterns as a result of instabilities in neural activity in the visual cortex. He also applies these models to the patterns found on mollusc shells.

Murray concludes with two chapters on epidemics. The favourite old examples — black death, venereal diseases and rabies — are all there, with the inevitable addition of AIDS and other newer diseases. Murray applies the model for the spread of rabies to the so-far hypothetical example of what would happen if the disease were to reach Britain. Assuming that an epidemic starts near the port of Southampton, he predicts that the wave front will reach London in approximately two years and the south of Yorkshire, in the north of the country, in approximately four years.

Murray has produced a magnificent compilation of mathematical models and their application in biology. I am sure that I shall refer to the text frequently, though I feel uncertain about attempting the exercises that conclude each chapter. The text is a fine exposition of calculus models in the biological sciences. I do, however, have some misgivings: the first three words that I looked up in the index were 'matrix', 'fractal' and 'chaos'. 'Matrix' is not there, but to be fair neither is 'differential equation'. 'Fractals' are not there either, but 'chaos' is discussed now and again, mainly in relation to the discrete logistic model. I regret that the book is not as comprehensive as I at first hoped, but nevertheless, couched in terms of calculus, there is a wealth of fascinating examples here. ☐

Making a real discovery

T. Cavalier-Smith

Prochloron: A Microbial Enigma. Edited by Ralph A. Lewin and Lanna Cheng. *Chapman and Hall: 1989. Pp. 129. £42, $53.*

EIGHTY years ago, Mereschkowsky suggested that chloroplasts of green plants and red, brown and other algae evolved from differently coloured symbionts that independently took up residence inside the cells of different protozoa. Although the origin of chloroplasts from prokaryotic (bacterial) symbionts has been firmly established for about a decade, it is still very uncertain whether chloroplasts evolved several times, as Mereschkowsky argued, or only once or twice.

Mereschkowsky's theory of multiple origins was given a considerable boost in 1975, when Lewin and Cheng showed that the photosynthetic green cells symbiotic in certain colonial seasquirts living on mangrove roots, sea shells and corals were not eukaryotic green algae, as previously thought, but gigantic green bacteria. What was most exciting about these bacteria was not their exceptional size (9–30 micrometres, a size more typical of eukaryotic cells) but the fact that they differed from cyanobacteria and resembled instead green-plant chloroplasts in two important respects: replacement of the blue or red phycobilin pigments by chlorophyll *b*; and the stacking of their photosynthetic (thylakoid) membranes. After first thinking of them as blue-green algae (now more often called cyanobacteria) Lewin therefore renamed these unusual green cells *Prochloron*, and placed them in a separate division which he called Prochlorophyta.

Many people concluded that Lewin and Cheng had discovered another of Mereschkowsky's hypothetical symbionts and that green-plant chloroplasts had evolved from *Prochloron* or some other prochlorophyte, whereas the phycobilin-containing chloroplasts of red algae and Glaucophyceae had obviously evolved from cyanobacteria. Expeditions to Pacific islands to collect material to test this idea have resulted in the publication of nearly 100 papers, whose conclusions are lucidly summarized in this excellent and valuable book.

Virtually everything significant known about *Prochloron* and its symbiosis with seasquirts is included, together with beautiful colour plates of the fascinating variety of didemnid seasquirts that harbour *Prochloron*. In several cases the seasquirts clearly gain nutritionally from cultivating *Prochloron* in their bodies. The main evolutionary conclusion to be drawn is that *Prochloron* is really not as fundamentally different from cyanobacteria as was once thought, and is probably not specifically related to the chloroplasts of green plants. Both Lewin and Stackebrandt now tend to accept the view, long argued by Chadefaud and myself, that *Prochloron* evolved from a cyanobacterium (by the loss of phycobilisomes and the associated evolution of chlorophyll *b* and thylakoid stacking) quite independently of green plant chloroplasts. Alberte suggests some possible selective advantages for these changes.

The recently discovered free-living prochlorophyte *Prochlorothrix*, to which the final chapter is devoted, also appears not to be specifically related to green chloroplasts. Because of the possibility of convergent multiple losses of phycobilisomes and origins of chlorophyll *b* (which differs from *a* in only one atom), one cannot even be sure that the prochlorophytes are monophyletic. It also remains possible, though perhaps unlikely, that green plants obtained their chloroplasts from the same cyanobacterium as did red algae but that euglenoids got theirs from a prochlorophyte. The discovery of a third unnamed type of prochlorophyte suggests that prochlorophytes could be more diverse than initially thought: even *Prochloron* should probably be split into at least three species. Atypical photosynthetic bacteria continue to be discovered sufficiently frequently to suggest that still more surprises may lie ahead.

Both Lewin and Stackebrandt touch on the problem of classifying the prochlorophytes. This group obviously belongs in the Eubacteria, not in the plant kingdom, despite Lewin's original creation of the botanical division Prochlorophyta. But the likelihood that these organisms evolved from cyanobacteria is insufficient reason to include them within the same family as cyanobacteria, as Stackebrandt suggests; that would be confusing and would undervalue their distinctiveness. The paraphyletic and exceedingly diverse class Photobacteria clearly should be abolished, as Stackebrandt implies. But instead one should treat Cyanobacteria and Prochlorobacteria (a better name than Prochlorophyta) as classes within a single new division — the Phycobacteria ('algal' bacteria) — which would include all those bacteria sharing the property of oxygenic photosynthesis with their descendants the chloroplasts. Phycobacteria differ sufficiently profoundly from purple and green anoxygenic bacteria to be a separate division.

An unusual and valuable feature of the book is the inclusion of abstracts of all the papers that have been published on *Prochloron*, which nicely complement the more discursive chapters on its cytology, biochemistry, symbiosis and phylogeny. The editors' very practical, and sometimes amusing, hints for collecting and handling *Prochloron* complete a first-rate work, the first devoted to the Prochlorobacteria. ☐

Sitting on the fence

David Lindley

Cold Fusion: The Making of a Scientific Controversy. By F. David Peat. *Contemporary Books; 1989. Pp.188. $16.95.*

YOU would think that anyone writing about the cold fusion affair would be sensitive to the dangers of hasty publication. Not F. David Peat, apparently. Like Stanley Pons and Martin Fleischmann, who went public on the basis of what turned out to be highly disputable results, Peat has produced an account of cold fusion based on skimpy research and incomplete data. He also shies away from pronouncing judgement. This may be partly because his story comes to a halt during September 1989, when it was still possible (with a little effort) to imagine that there might be something to Pons and Fleischmann's claims, but is more a consequence of Peat's complete reluctance even to try to sift from the assertions and counter-assertions any measure of truth.

Peat's telling of the story adds little to what anyone who followed the comprehensive newspaper and magazine coverage will already know. Even so, Peat makes some mistakes with his chronology: he conflates the Materials Research Society meeting in San Diego, at which Robert Huggins unconvincingly defended his claim for excess heat, with the Electrochemical Society meeting in Los Angeles, at which Pons and Fleischmann similarly defended their claim for excess heat.

Nor is Peat's account of the science of cold fusion very penetrating. Two chapters of the book are occupied with routine expositions of nuclear physics, 'hot' fusion, solar energy, the chemistry of palladium and so on. Observing the quantity of theoretical ideas thrown out in response to Pons and Fleischmann's claim, Peat says "theoretical physicists and chemists appear to have no problem in accounting for cold fusion", a sunny judgement presumably based on the notion that a thousand completely wacky ideas weigh about the same as one or two moderately plausible ones. But in order to maintain some critical distance, the author adds "only time will tell how well [the theories] stand up to a closer examination".

The problem with Peat's book is not that it is conspicuously wrong anywhere, but that it is so stubbornly uninformative. Throughout the tale there are disputes, disagreements and contradictions, all of which offer the author opportunities to dig deeper, unearth the truth and in the process bring to light some aspect of the nature of scientific discovery or the character of the participants. But at every such opportunity, Peat refrains from comment and moves hastily on. "For some scientists," he writes near the beginning, "the Fleischmann and Pons announcement produced a sense of elation. But for others, it was a matter of skepticism." Seven chapters later, having followed the controversy through a number of rowdy scientific meetings and heard most of the relevant pros and cons, we reach Peat's final, balanced evaluation: "Cold fusion may lead nowhere. Or we may be standing on the threshold of something extraordinary." ☐

Clock watching

Owen Gingerich

Empires of Time: Calendars, Clocks, and Cultures. By Anthony Aveni. *Basic Books: 1989. Pp. 371. $24.95.*

"Time, like an ever-rolling stream, bears all its sons away", runs a line in the familiar hymn. But is time really, objectively, like an ever-flowing stream, or is that just a Western cultural notion? Such is the central question of this aptly titled book from the astronomer turned anthropologist Anthony Aveni.

At the heart of Aveni's discourse are three chapters dealing with Mayan, Aztec and Incan time. The author is obviously in command of this material, which has been close to his research interests for more than a decade. These time systems, devoid of borrowings from Western civilization, enable him to raise the "big question of human nature": given basically the same stimuli, do different people in different places all react to what they see in the same way? The answer is loud and clear: the intricately interlocking calendars of the Maya or the geometrically land-mapped calendars of the Incas are far removed from our own views of time, so wildly different that even writers of science fiction could hardly have dreamed them up.

Aveni focuses his account on these pre-Columbian civilizations by first considering a fascinating group of tribal societies — the Mursi and Nuer in Africa, the Bororo from central Brazil and the Trobrianders from New Guinea, these last with their edible timekeeping palolo worm. (These marine annelids spawn every year following the full moon in mid-autumn, allowing the Trobrianders to keep their lunar calendar in synchronism with the solar seasons.) Aveni's discussion ranges from basic biological rhythms, to the history and vicissitudes of the Western calendar, and even to a romp through modern cosmology. Although the book is somewhat uneven in quality, these topics offer an intriguing and enlightening menu for the general reader.

As a practicing archaeoastronomer, Aveni takes a decidedly sceptical view of the claims of nascent science at Stonehenge but, he asks, "Isn't there a bit of science in a ritual conducted at a time of year signaled by the passage of sunlight down an avenue or through a stone archway?". One might wish that he had evinced even more scepticism: Aveni cites reports that potato metabolism anticipates barometric pressure by two days, mentions that the Latin word *mens* signified "moon", and reckons that the Age of Aquarius will begin in AD 2137. (By my own calculations, it began well over a century ago.) It is also hard to believe his claim that the gregorian calendar reform was antisemitic.

These quibbles aside, Aveni has put together a well-written and handsomely illustrated volume. His exploration of the mysteries of time provides an eminently stimulating read, wonderfully suitable for the Christmas break. ☐

New in paperback

- First published in 1988, *Time in History* by G. J. Whitrow is available in paperback. The volume discusses the general influence of time on the mental outlook and way of life in different ages and civilizations, as well as the history of the measurement of time. Published by Oxford University Press, price £5.95, $8.95.
- *The Dread Disease: Cancer and Modern American Culture* by J. T. Patterson is now issued in paperback by Harvard University Press, price £11.95, $14.95 (see review in *Nature* **330**, 285; 1987).
- *Electricity and Magnetism* Volumes I and II, by B. I. Bleaney and B. Bleaney, are available as a 3rd edn in paperback from Oxford University Press. Price Vol. I £9.95, $19.95; Vol. II £13.50, $26.95.
- *Universality in Chaos*, 2nd edn, by P. Cvitanović has been updated by the addition of several articles reflecting the developments in universality theory. Published by Adam Hilger, price £15.

Distilled delight

D.H. Perkins

The Experimental Foundations of Particle Physics. By Robert N. Cahn and Gerson Goldhaber. *Cambridge University Press: 1989. Pp. 428. £30, $49.50.*

PROGRESS in physical science depends on the close interplay between experiment and theory, and nowhere has this been more true than in the physics of elementary particles. Many standard texts on this subject tend to emphasize the beauty, conciseness and all-embracing nature of theoretical principles and ideas, so it is a pleasure to review a text in which, for a change, discussion of experiments takes pride of place.

Cahn and Goldhaber describe key experiments in twelve areas of particle physics, covering the discovery, over the years, of the various lepton and quark constituents of matter and the nature of the interactions between them. The authors have struck an excellent balance in what must have been a difficult choice of material.

The book is intended for advanced undergraduates and graduates in physics. The text in each chapter introduces a particular area of the field, presenting the basic physical concepts and background information necessary for an understanding of the significance of, typically, three or four original key papers, which are reprinted at the end of each chapter. The contents range from discovery of the neutron, positron, muon and pion in the 1930s and 1940s, to the study of "strange" particles and hadron resonances in the 1950s and 1960s, which led to the quark model and was crowned with the discovery of the massive "charm" and "beauty" states in the 1970s. There are excellent chapters on the study of weak interactions, of the strong forces between quarks, and on the discovery of neutral currents and the W and Z bosons validating the electroweak model unifying the electromagnetic and weak interactions.

I believe the authors' assessment of the role of the various experiments to be well considered, authoritative and scrupulously fair. I have to say, however, that I sometimes found the balance between the space devoted to different topics to be slightly odd. The discovery at CERN of W and Z bosons — which were a crucial prediction of the electroweak model and for which the scientific world had waited 15 years — is covered in 1½ pages of text, whereas the Stanford discoveries of charm quarks and the tau-lepton — also very important — get 20 pages. Presumably this simply reflects the north Californian origin of the authors. There are few *faux pas*, although omitting the name of Bruno Touschek in a discussion of colliders must be one of them.

Included at the end of each chapter is a set of problems. Many of these are well beyond undergraduate level and they are mostly of a theoretical nature. What a pity that, in a text devoted to the experimental foundations of the subject, there are not more practical exercises which involve calculating a real number! My only other criticism is that a little discussion of accelerator and detector technology and development would have been useful, as these form the backbone of the experimental scene. Regarding the quality of presentation, I have to say that an otherwise well-produced book was for me marred by the poor quality of reproduction of the original papers, particularly in the first three chapters.

In summary, I believe this text to represent a major achievement in collecting, analysing and distilling for the reader, material forming an intensely exciting chapter in modern science. □

D. H. Perkins is Professor of Elementary Particle Physics and head of the Nuclear Physics Department at the University of Oxford, Keble Road, Oxford OX1 3RH, UK.

Spinning out

P.J. Hore

One and Two Dimensional NMR Spectroscopy. By Atta-ur-Rahman. *Elsevier: 1989. Pp.578. Dfl.355, $186.75.*

NUCLEAR magnetic resonance (NMR) spectroscopy has changed almost beyond recognition in the past decade. A glance through the literature reveals a truly staggering array of ingenious and specialized techniques for determining the structures and motions of molecules. Assisted by developments in computer and magnet technology, this metamorphosis has been made possible by the ease with which long-lived coherent superpositions of nuclear spin states (coherences) can be created and manipulated using pulses of coherent, monochromatic, radiofrequency radiation.

No longer are chemists content simply to monitor the equilibrium state of the nuclear spins in a molecule subject to the restrictions of spectroscopic selection rules; rather they tailor the spectrum to suit their needs, shifting spin polarizations and coherences around the molecule so as to map out its chemical structure. A crucial factor in this revolution has been the move away from the conventional one-dimensional approach. Two-dimensional NMR, in which signals are functions of two frequency variables, is now routine, while the first forays into a third frequency dimension have occurred in the past two years. The relief of crowding in the spectra of complex molecules afforded by two-dimensional methods, together with their ability to reveal correlations between nuclei, have led to previously undreamt of achievements, most notably the determination of the complete three-dimensional structure of small proteins.

To take the greatest advantage of these new NMR techniques, the chemist needs to understand the physics underlying them. Atta-ur-Rahman's book is one of a handful of recent publications that aim to provide such insight, while also offering advice on the choice of experiment and guidance on interpretation of spectra. The book is restricted to proton and carbon-13 NMR of liquids, and deals with essentially every significant experiment up to about 1986. An undergraduate knowledge of NMR is assumed, but not much else. Most chapters finish with exercises in spectral interpretation chosen from the author's own research in natural product chemistry.

Atta-ur-Rahman succeeds in conveying the scope and power of one- and two-dimensional NMR and shows clearly how structural information can be extracted. But he is less convincing when discussing how radiofrequency pulse sequences actually work. This he does by means of Felix Bloch's semi-classical vector model which, although simple and pictorial, cannot satisfactorily handle multiple quantum coherence or coherence transfer. As most modern techniques involve one or both of these elements, this is really a severe limitation. A newcomer to modern NMR would surely be better advised to embrace the product operator formalism to which the author devotes his final, short chapter. Once mastered, this approach requires only simple algebra and determination to enable the inner workings of complex experiments to be seen.

Sadly, there is a sufficient number of typographical errors to be irritating and, in places, confusing or misleading. Nor is the reader helped by a poorly organized introductory chapter and a rather imprecise style of writing. In short, this is a comprehensive and much-needed book, but it has serious flaws. □

P. J. Hore is in the Physical Chemistry Laboratory, University of Oxford, South Parks Road, Oxford OX1 3QZ, UK.

■ Two new volumes in the series *Methods in Enzymology* bear witness to the remarkable transformation in the practical application of NMR spectroscopy in the past 10 years. Volume 176, *Nuclear Magnetic Resonance* part A, covers basic techniques and methods for studying protein dynamics. Volume 177 (part B) describes protein modifications. Both volumes are published by Academic; part A is $65, £46.50, part B (to be published in January 1990) is $65, £46.50.

The role of mantle plumes in the development of continental drainage patterns

K. G. Cox

Department of Earth Sciences, Parks Road, Oxford OX1 3PR, UK

The geomorphology of three continental flood-basalt provinces supports a recent model for the generation of such provinces by melting of hot mantle plumes. Characteristic drainage patterns indicating topographic doming associated with plume activity are still preserved after up to 200 Myr. Crustal thickening by magmatic underplating is the most likely cause of the persistence of such features.

THE plume hypothesis was first applied to continental areas as an explanation of flood-basalt volcanism by Burke and Dewey[1]. In its new version White and McKenzie[2] postulate the former existence of plumes with specific sizes and locations, and it is this aspect of the model that I shall test. The model postulates that plumes of hot mantle material rise as relatively narrow columns that spread laterally at a high level to produce areas of anomalously hot asthenosphere up to 2,000 km across. When a plume rises beneath a continent the dynamic and thermal effects may produce up to 2 km of surface uplift in the centre of an extensive dome. Fracturing of the dome by gravitational forces may produce rifts and massive amounts of basaltic volcanism as the anomalously hot mantle undergoes decompressive melting. If conditions are favourable the rift may widen and a new ocean will be formed. Plume activity itself produces uplift that is strictly temporary, but even after it has ceased, the continental areas affected characteristically remain topographically high, a feature that has been ascribed to crustal thickening caused by magmatic underplating[3,4].

The plume hypothesis provides a framework in which many features of the geology of non-orogenic continental areas can be considered, and here I present geomorphological evidence that provides strong support for the model.

Drainage patterns over continental swells

The idea of great continental uplifts (swells) with rifted crests is an old one (see, for example, ref. 5). Figure 1 shows Cloos' drawing[5] of the Afro-Arabian dome, split by the Red Sea, Gulf of Aden and Ethiopian rifts. This figure illustrates the fundamental components of the morphology: outwardly tilted blocks separated by rifts.

If continental break-up takes place, a typical continental flood-basalt province in a particular continent ought initially to display a morphology appropriate to (roughly) half of such a structure. The unrifted flanks of the dome should be characterized by river systems draining away from the new continental edge (dome-flank systems), whereas failed arms of the rift system should lead drainage towards the new ocean (rift-related systems). Figures 2–6 illustrate the drainage patterns of three areas of Gondwanaland affected by flood-basalt volcanism during and at the end of the Mesozoic. The circles are taken directly from White and McKenzie's diagrams and indicate their estimates of the extents of the plume tops. I believe these figures speak for themselves in showing a remarkable general correspondence between postulated plume locations and the occurrence of the predicted drainage patterns. The details (especially the extent to which the patterns deviate from the strictly radial and the extent to which they may have been influenced by other factors such as more linear uplifts along rift shoulders or along the continental margins) will be discussed elsewhere.

The Deccan

The Deccan province[6] (Fig. 2) is the youngest of the three, having formed at about the time of the Cretaceous/Tertiary boundary[7,8]. The west coast of peninsular India was formed at about the same time as the eruption of the traps by the separation of India and the Seychelles bank[9]. This has been interpreted as due to a ridge jump as India passed over a plume, now believed to be situated beneath Reunion[10]. Deccan geomorphology and uplift have been described[11-13]. The present western margin of peninsular India is marked by the escarpment of the Western Ghats, the northern half of which is cut into the Deccan basalts. Most rivers rise close to the west coast (sometimes within as little as 50 km) and drain eastwards into the Bay of Bengal, although in the Malwa region in the north, drainage is north-easterly into the Ganga valley. I interpret the peninsula as a whole as the flank of the remaining eastern half of the original dome. I assume that if an opposing half existed, that it has been disrupted by crustal thinning and now lies below sea level in the Seychelles and the Saya de Malha bank.

In the north, examples of exceptional drainage, towards the new ocean, are provided by the west- or south-flowing fault-controlled valleys of the Tapti, Narmada and Gulf of Cambay systems[14,15], which are interpreted as failed rift arms.

Southern Brazil

The coast of southern Brazil was formed in the Lower Cretaceous[16,17] by the opening of the South Atlantic. Co-eval volcanism is represented now by the extensive basalts and rhyolites of the Paraná Basin[18] (the Serra Geral Formation) and

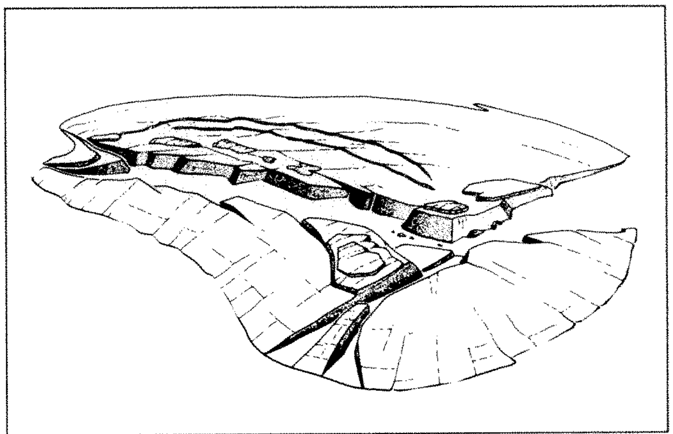

FIG. 1 The Afro-Arabian dome, redrawn from ref. 5. The view is from the south with Africa in the foreground, separated from Arabia by the Red Sea (left) and the Gulf of Aden. The Ethiopian rift system cuts the African side of the dome in the foreground. If the drawing is turned upside down a remarkable similarity is observed between the African side and the morphology of peninsular India (Fig. 2), with the Ethiopian rift playing the part of the Narmada and Tapti rifts.

by a relatively small opposing outlier on the African side at Etendeka in Namibia[19] (Figs 3 and 4). In Brazil the coastal escarpment (the Serra do Mar) rises steeply for a distance of ~1,500 km between Porto Alegre in the south and Vitoria in the north, and the plateau edge inland attains heights of ~2,000 m above sea level. Geomorphologically this area is similar to the Deccan, the predominant drainage flowing westwards, directly away from the new ocean. Unlike the Indian case, however, the presence of the Andes results in the inward drainage being collected by the Paraná river system and returned to the Atlantic by the River Plate, at a point well to the south of the Paraná basalt outcrop. On the African side, only small areas of the corresponding volcanics are preserved, but there is an extensive coast-parallel topographic high, stretching from the northern part of the Cape Province of South Africa through Namibia and Angola. This directs much of the drainage away from the coast into the Kalahari Basin. I interpret the Serra do Mar and Cape-Angola topographic highs as representing the opposing halves of a single original structure.

Unlike the Deccan the Paraná dome does not seem to have been endowed with failed-rift arms.

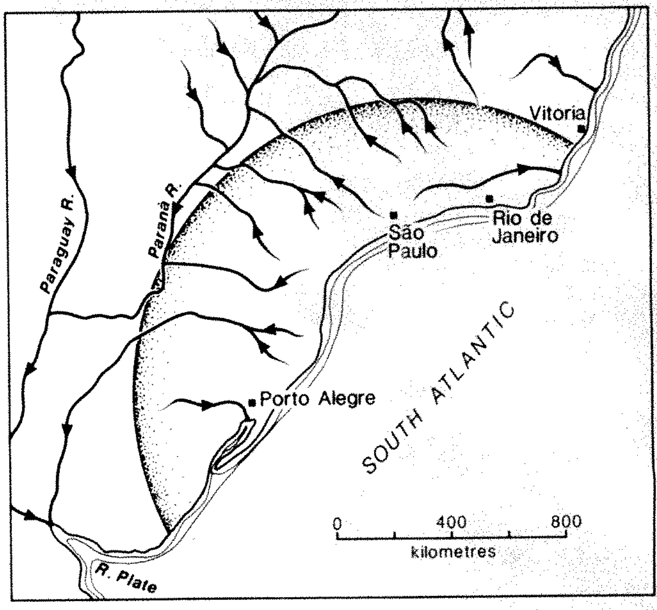

FIG. 3 Drainage pattern of southern Brazil with superimposed plume[2]. Except in the south near Porto Alegre, dome-flank drainage is dominant.

The Karoo

In southeastern Africa the main peak of volcanism, associated with the separation of Africa and Antarctica, took place in the Lower Jurassic[20] and the topographic signature is more difficult to read. The area covered by remnants of the volcanism, the Karoo volcanic province, is huge, extending in the north-east from southern Malawi and the vicinity of Mozambique Island, to the north-west at Mariental in Namibia, and thence southwards over the remainder of the continent. Rocks of equivalent age and composition are found in the Dronning Maud Land area of Antarctica, where clearly the other 'half' of the province is located. Ice-cover, however, precludes consideration of Antarctic topography in the present work.

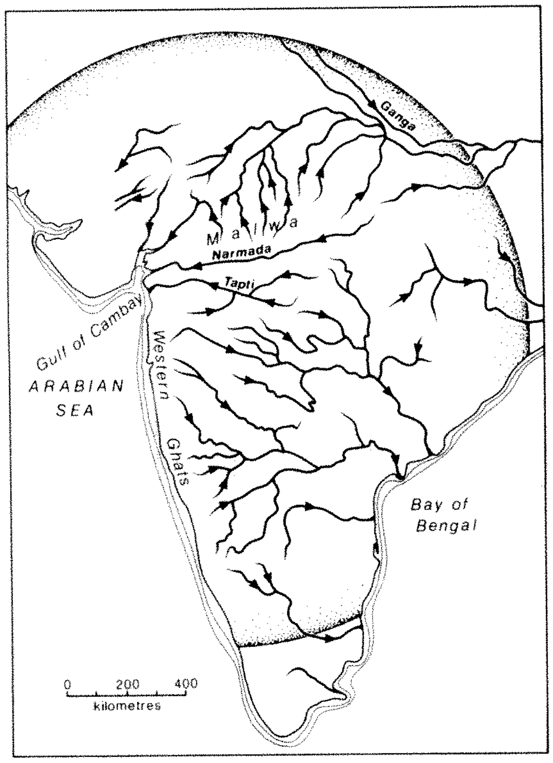

FIG. 2 Drainage pattern of peninsular India with the postulated Deccan plume[2] superimposed (stippled circle). Most of the peninsula preserves dome-flank drainage, also seen in the Malwa area in the north. The Gulf of Cambay, Narmada and Tapti systems consist of rift-related drainage. The westernmost left-bank tributary of the Tapti illustrates river capture of the dome-flank drainage by the rift-related system.

Because of its great extent in Africa and because of the spatial overlap of the Karoo province with the southern end of the East African rift system, it is not immediately clear which topographic features should be related to the proposed Karoo plume. High ground broadly parallels the east coast, running from Natal in the south (the Drakensberg) through the eastern Transvaal and the eastern highlands of Zimbabwe into southern Malawi and neighbouring parts of Mozambique. Maximum elevation is reached in the heavily dissected mountains of Lesotho (Thaba Ntlenyana, 3,500 m) but there are large tracts of plateau country at ~2,000 m above sea level in the Orange Free State and the Transvaal. All the high ground mentioned lies within White and McKenzie's postulated plume top.

Two major rivers, the Limpopo and the Zambezi, flow eastwards into the Indian ocean, interrupting the coast-parallel topographic high. Both are zones of Karoo-age rifting[1,21], and hence analogous to the Narmada in the Deccan province. The greater age of the Karoo province, however, has resulted in considerable extension of the drainage basins of these rivers, leaving the dome-flank sectors much reduced. There are still two areas, however, where the characteristic drainage patterns are well preserved.

A pattern analogous to that of southern Brazil and peninsular India is still obvious in the southern part of the province (Fig. 5). Here there are no rifts to disturb the simple pattern of westward drainage off the crest of the Drakensberg into the Orange River and Vaal River systems. The Orange River rises only 150 km from the south-east coast but flows into the Atlantic at Oranjemond, 1,400 km due west (Fig. 4), so it is evidently a classic case of drainage directed away from the new ocean. The dome-flank drainage is also excellently preserved in north-western Zimbabwe where the right-bank tributaries of the Mid-Zambezi flow with sub-parallel courses to the north-west, at right angles to the Zambezi itself (Fig. 6).

The evidence from Africa supports White and McKenzie's positioning of the Karoo plume and its areal extent. It is not obvious, however, that the Antarctic side of the plume is realistic in their presentation because it takes no account of volcanism through the Transantarctic mountains (see, for example, refs 22, 23 for further discussion).

Antiquity of drainage patterns

Major continental drainage patterns have often been postulated as being of considerable antiquity[24] although they are obviously difficult to date (see summary in ref. 25). Here the extremely close spatial correspondence between proposed plume locations and predicted drainage systems indicates a direct genetic relationship and, by implication, that the river systems originated at the same time as the plume activity. Thus for example, the Orange system must have originated in the Jurassic, probably at or at about the time of the Lower Jurassic peak of Karoo activity[26] about 190 Myr BP (before present). Between the Kalahari and Oranjemond, the Orange cuts a considerable gorge through the Cape–Angola high. The river is <200 m above sea level, but is closely bounded, especially to the north, by substantial tracts of country at elevations of 1,500 m or more. The Orange is clearly antecedent to the Cape–Angola high, a conclusion consistent with the postulated Jurassic age of the drainage system, and the implied Lower Cretaceous age of the high, as the eastern half of the Paraná dome.

The Orange thus predates the South Atlantic and presumably originally flowed on into the general region of Buenos Aires, lending weight to speculation[25] about the possibility of other African rivers such as the proto-Congo flowing across South America.

Surface uplift

The plume model involves initial uplift of the existing land surface, in response to the dynamic effects of the plume. This may have initiated the drainage patterns observed, yet they still exist, and in all cases the postulated plumes are now far from the provinces concerned. White and McKenzie argue that further magmatic material accretes to the base of the crust during plume activity (the phenomenon of underplating) and that the resulting crustal thickening causes the basalt provinces to remain topographically high in the long term. This hypothesis is based on petrological arguments[27] and is supported by wide-angle seismic experiments in the vicinity of rifted areas (some of which have been drilled), but it is difficult to test directly. For further studies of this problem, however, it is important to try to quantify the uplift.

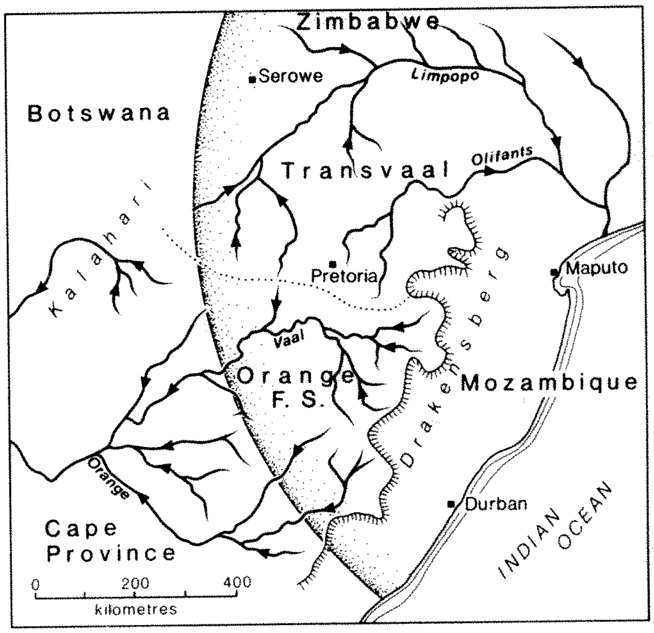

FIG. 5 Drainage patterns in southeastern Africa, with Karoo plume superimposed. Dome-flank drainage is preserved west of the Drakensberg escarpment (Orange River and Vaal systems). The dotted line separates dome-flank drainage in the south from rift-related (Limpopo) drainage in the north. Note the extreme enlargement of the catchment of the latter compared with the Narmada–Tapti system in Fig. 2.

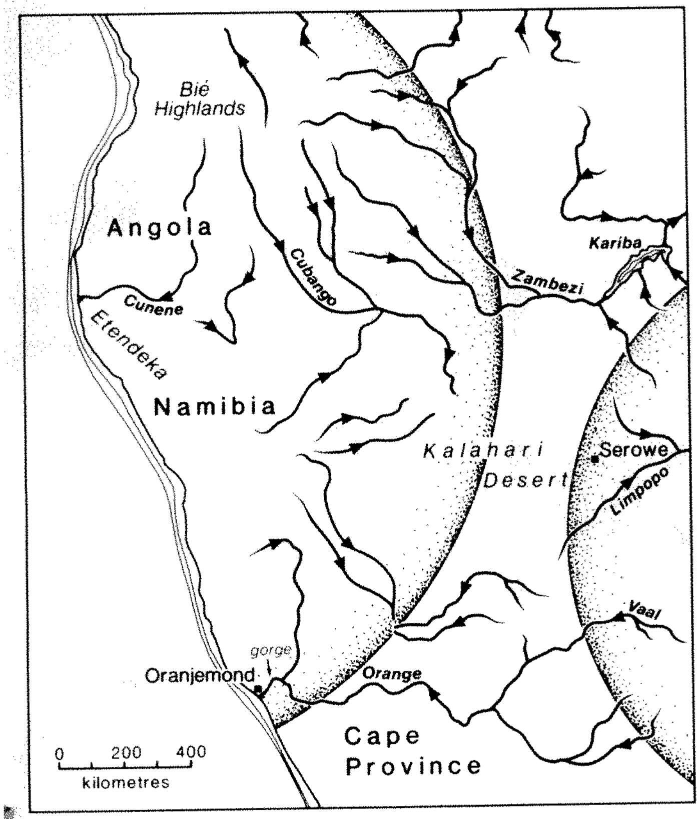

FIG. 4 Drainage patterns of the Cape–Angola topographic high, with the Paraná plume (left) and part of the Karoo plume (right). An irregular dome-flank pattern is preserved draining eastwards into the Kalahari. Note the Orange River gorge, where antecedent drainage cuts the younger uplift.

Surface uplift (the term is used to mean that the average elevation of the ground increases[28]) on a regional scale is difficult to demonstrate. Here I shall make only a very general argument, mainly for the Karoo province, that suggests the likelihood of about 1.5 km of post-Lower-Jurassic surface uplift for the Drakensberg region. The Palaeozoic history of a large part of Gondwanaland, particularly the western and southern regions (the Paraná Basin[29], the Karoo[30], and the Transantarctic Mountains[31]) was one of platform sedimentation. In the Lower Palaeozoic much of this showed marine influences, but by the Permian, deltaic and fluviatile environments were widespread. By the beginning of the Mesozoic a vast area had been transformed into the subaerial desert over which the Cave Sandstone was deposited (southern Africa) and, where not terminated by volcanism, these conditions persisted right through the Jurassic into the Lower Cretaceous (for example, in the Botucatu sandstones of the Paraná Basin). The Palaeozoic/early Mesozoic history is thus one of an extensive depositional basin slowly filling up and eventually becoming a subaerial desert.

After the volcanism, the whole area has behaved completely differently, and the dispersed fragments of this region of Gondwanaland have been high-standing erosional environments. This constitutes a strong general argument in favour of long-lasting surface uplift.

I assume that the Cave Sandstone desert lay fairly low at the time of initial Karoo volcanism, perhaps <1,000 m above sea level. The sub-basalt unconformity now lies at 2,000 m in Lesotho, but more importantly, over a large area to the north of this, through the Orange Free State and the eastern and northern Transvaal, although the basalts have largely been removed by erosion, the Karoo sedimentary sequence is still widely preserved. This is a plateau area unincised by major canyons, so the average elevation of large tracts is clear. Much of it approaches 2,000 m, and the implication of the Karoo geology is that the basalt unconformity lay not far above the present erosion surface. Returning to the initial assumption about the elevation of the desert, this indicates surface uplift of 1-2 km.

I have speculated that the Kalahari basin might owe its existence to the fact that it was unaffected by both the Karoo and Paraná volcanic episodes, hence remaining free of the associated uplift[20] (the 'passive basin' model[1]). Much of the basin lies 500-1,000 m above sea level. There has been both post-Jurassic erosion and deposition[30] but I speculate that the present elevation is still about the same as that of the general pre-Jurassic land surface of southern Africa. The Kalahari is just the present-day continuation of the great Cave Sandstone and Botucatu desert, and its present elevation (about 1.5 km below the Transvaal/Orange Free State plateau) gives some support to the calculation above.

Erosion surfaces

Thus far I have tried to view the geomorphological evolution of the areas discussed in terms of consequences of the initial plume activity, which is in some cases very old. Yet the geomorphological literature of the Gondwanaland continents is rich in references to cyclical-erosion surfaces and scarp retreat[32-34] and in many cases relatively recent, such as late Cenozoic, uplift events have been recognized. Partridge and Maud[34] particularly stress the episodic nature of uplift. Can the two views be reconciled? Can the whole evolution be seen in terms of a single original cause, or is it necessary to postulate a series of apparently unrelated uplift events?

A reconciliation may be found by postulating mechanical coupling between the continental crust and the newly-formed oceanic crust. After an early surface uplift has created a coast-parallel topographic high, erosion of the swell promotes rock uplift (used in the sense of England and Molnar[28] to indicate upward movement of bedrock) in response to denudation and isostatic adjustment. The continental margin is subjected to opposing stresses. Inland the bedrock is travelling upwards; on the other side the oceanic crust is, if anything, likely to founder. I assume that flexure of the lithosphere can accommodate, up to a point, these conflicting demands. Beyond that point the continental margin may respond by fracture and undergo local surface uplift. Despite the fact that rock uplift is continuous in the continental interior, scarp retreat in response to episodic marginal uplift, with concommitant changes of the base level of erosion, can generate the impression of episodic uplift throughout.

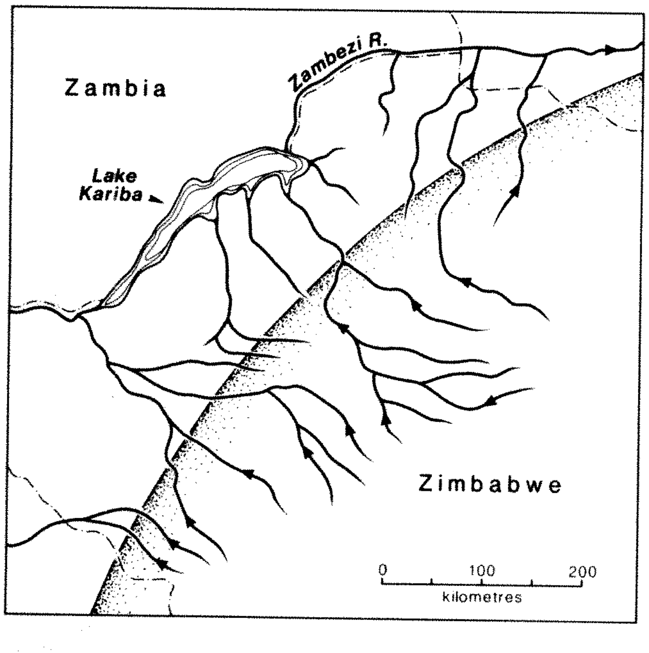

FIG. 6 Drainage in the northwestern part of the Karoo province, with part of the Karoo plume. Right-bank tributaries of the Zambezi are shown, and represent well preserved dome-flank drainage. The southeastern part of the area is occupied by left-bank tributaries of the Limpopo, the enlarged rift-related system of which the southern side is shown in Fig. 5.

Drainage-pattern preservation and plume location

After initial formation, dome-flank drainage patterns come under attack from rift-related systems. Within continental marginal zones the latter flow at low topographic levels relative to the adjacent dome-flank systems, and consequently expand their catchments by river capture. Some of the left-bank tributaries of the Tapti (Fig. 2) show this in an early stage (65 Myr after initiation), and the huge bite the Limpopo system has taken out of the Karoo dome flanks in 180 Myr is notable. Preservation is thus partly related to the age of the province, but dome-flank drainage patterns are best preserved in areas where the volcanics, or flat-lying sub-volcanic sediments, are still present or where they have only relatively recently been removed by erosion. These conditions are met by the Deccan, much of the Paraná, and the Orange Free State and Transvaal, where preservation is aided by the presence of the widespread flat-lying sedimentary rocks of the Karoo Basin. In northwestern Zimbabwe a thin veneer of basalts is still present, accounting for the very regular pattern of the mid-Zambezi right-bank tributaries.

By contrast, the Cape-Angola topographic high is deeply eroded, as the towering Jurassic/Cretaceous[35] plutons of Damaraland testify. Fission-track studies[36] indicate several kilometres of erosion during the Cretaceous. As a result the drainage system into the Kalahari basin, although still recognizable, has now adopted a more complex pattern as it adjusts to heterogeneous basement rocks. Apart from the small Etendeka remnant, whatever basalt cover was present has been completely removed.

White and McKenzie positioned their plumes using two main criteria: the centre had to coincide with the pre-drift position of a known hotspot if present, and the circle had to include the known seaward-dipping reflectors as far as possible. Here I have shown the expected drainage patterns, which support the model despite its evident simplicity. Future studies of denudation, for example by fission-track methods, and more detailed analysis of drainage patterns that are less obviously preserved, however, may enable more extensive mapping of the areas influenced by plumes. ☐

On the basis of comparative studies of known antibody structures and sequences it has been argued that there is a small repertoire of main-chain conformations for at least five of the six hypervariable regions of antibodies, and that the particular conformation adopted is determined by a few key conserved residues. These hypotheses are now supported by reasonably successful predictions of the structures of most hypervariable regions of various antibodies, as revealed by comparison with their subsequently determined structures.

THE relationships between the amino-acid sequences of immunoglobulins and the structures of their antigen-binding sites are important for understanding the molecular mechanisms of the generation and maturation of the immune response and for designing engineered antibodies. Antigen-binding sites are formed by six loops of polypeptide, the hypervariable regions; three from the variable domain of the light chain (VL) and three from the variable domain of the heavy chain (VH), denoted L1, L2, L3, and H1, H2, H3, respectively (Fig. 1*a*). Within the domains, the loops are connected to a β-sheet framework whose structure is conserved[1,2]. The specificity and affinity of the binding sites are governed by the structures of the six hypervariable regions[3,4].

Two models can be proposed for the relationship between the amino-acid sequence and structure of the binding-site loops. In one model, different sequences produce different conformations for both the main chain and side chains of the loops. Because hypervariable regions have different sequences in different antibodies, this model implies that each region adopts a different conformation in different antibodies. In the other model, antibodies have only a few main-chain conformations or 'canonical structures' for each hypervariable region. Most sequence variations would only modify the surface provided by the side chains on a canonical main-chain structure. Sequence changes at a few specific sets of positions would switch the main chain to a different canonical conformation.

Canonical structure model

Experimental evidence indicates that the canonical structure model describes the relationship between amino-acid sequence and structure for at least five of the six hypervariable regions[5-9]. Kabat *et al.*[5] found conserved residues at sites within certain sets of hypervariable regions and suggested that they had a structural role. Padlan and Davies[6], and more recently de la Paz *et al.*[7], showed that some of the hypervariable regions in the immunoglobulins of known structure have the same main-chain conformation in spite of several differences in sequence.

Chothia and Lesk[8] identified the residues that through packing, hydrogen bonding, or the ability to assume unusual values of the torsion angles ϕ, ψ or ω, are primarily responsible for the main-chain conformations of the hypervariable regions in the structures then known—the Fab fragments of NEW (ref. 10), McPC603 (ref. 11), KOL (ref. 12) and J539 (ref. 13) and the VL domains of REI (ref. 14) and RHE (ref. 15). The conformations are determined by the interactions of a few residues at specific sites in the hypervariable regions and, for certain loops, in the framework regions. Hypervariable regions that have the same conformations in different immunoglobulins have the same or very similar residues at these sites (Fig. 1 and Table 1). Examination of the amino-acid sequence of the antibody D1.3 showed that its hypervariable regions are the same size as those in known structures and contain the same or similar residues at the sites responsible for known conformations[9]. On the basis of these observations the atomic structure of the VL–VH dimer of D1.3 was predicted before its experimental determination. Comparison of this predicted structure with the preliminary crystal structure showed that the conformations of four of the hypervariable regions had been predicted correctly; the conformation of L3 was significantly different from that predicted, and

H1 had a very different fold from that predicted[9]. (We report below that the refined conformation of D1.3 corresponds more closely to the predicted structure.)

An examination of the library of the known immunoglobulin sequences shows that many immunoglobulins have hypervariable regions that are the same size as those in the known structures and contain the same or closely related residues at the sites responsible for the known conformations[8]. These observations indicate that for at least five of the hypervariable regions there is only a small repertoire of canonical main-chain conformations and that the conformation actually present can often be predicted from the sequence by the presence of specific residues.

The accuracy of the canonical structure model for immunoglobulin binding sites depends on (1) the correct determination of the sets of residues responsible for the observed conformations and (2) changes in the identity of residues at other sites not significantly affecting the conformations of the canonical structures. The model can be tested, refined and extended by using it to predict the atomic structures of binding sites in immunoglobulins before their structures have been determined by X-ray crystallography.

We have now tested the canonical structure model by using it to predict the structures of four immunoglobulins before their structures had been experimentally determined. These immunoglobulins are HyHEL-5 (ref. 16), HyHEL-10 (ref. 17), NC41 (ref. 18) and NQ10 (S.S., P.M.A. and R.J.P., manuscript in preparation). The analysis of the amino-acid sequences of these immunoglobulins indicated that 19 of their 24 hypervariable regions should have conformations close to known canoni-

The residues listed here (single-letter code) are those that form the hypervariable regions and those in the framework regions that are important for the observed conformations of these regions[8]. The hypervariable regions are taken as those outside the framework β-sheet[8]. Except for H2, they are similar to, but not identical with the regions that show high sequence variations and which Kabat *et al.*[26] use to define hypervariable regions. The sequences are grouped so that those that have the same main-chain conformation, or canonical structure, are adjacent. The canonical structure numbers used below refer to the conformations shown in Fig. 1. The residues in the hypervariable and framework regions that are mainly responsible for these conformations[8] are indicated by an asterisk. The classification and sequence requirements of the H2 conformations have been revised in the light of work described here and elsewhere[28]. For each hypervariable region the number of human and mouse sequences listed by Kabat *et al.*[26] are given. We also give the percentage of these sequences that are the same size as the known canonical structures and have the same residues at the positions marked by an asterisk.

† Canonical structure 4 is illustrated in Fig. 4. Although the size of the known L1 structures varies between 6 and 13 residues, they have closely related folds with residues 26-19 and 32 packed against the framework in the same conformation[8]. The remaining residues form a turn or loop on the surface (Figs 1 and 4). The ends of the long loops have some flexibility. There are another 25% of the human sequences and 20% of the mouse sequences that have one more residue than structure 2, or one fewer than structure 4, and whose sequences satisfy the requirements listed above. It is expected that these differ only in the conformations of the tips of the surface loops.

‡ The H1 hypervariable regions with canonical structure 1 have very similar conformations: the r.m.s. differences in the coordinates of their main-chain atoms are 0.3–0.8 Å. The H1 regions in NEW and HyHEL-10 only partly satisfy the sequence requirements for structure 1 and have a distorted version of its conformation.

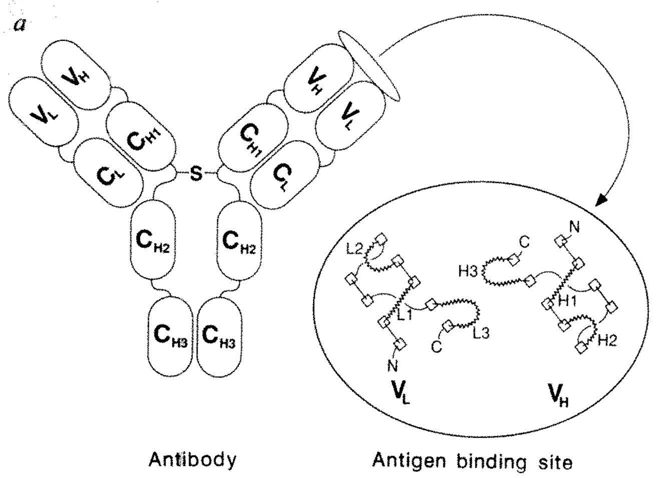
§ The H2 region here comprises residues 52a–55. The region with high sequence variation is 50–65 (ref. 26). In the known structures the main-chain conformation of 50–52 and 56–63 do not differ significantly[8] (Fig. 1*b*). (*), The residues at positions 55 or 54 in the canonical structures 2, 3 and 4 have residues with positive values for ϕ and ψ, and usually, but not in all cases, Gly, Asn or Asp is found at these sites. For a sequence to match that of canonical structure 2, 3 or 4 the presence of these residues at sites 54 or 55 is required.

cal structures. We then compared the predicted structures of these hypervariable regions with the subsequently determined structures. Another immunoglobulin structure, 4-4-20 (ref. 19) has recently been reported. We did not have the opportunity to predict the structure of 4-4-20 before its experimental determination, and we discuss here only how its hypervariable regions have the conformations expected from the known canonical structures. Also, we report that the refined conformation of D1.3 (ref. 20) corresponds more closely to the predicted structure.

Model building procedure

The main-chain conformations of the hypervariable regions in the Vκ and VH domains of known structure are shown in Fig. 1. The residues responsible for these conformations are listed in Table 1. Each hypervariable region in the immunoglobulins of unknown structure was examined to determine (1) whether it has the same size as any homologous hypervariable region of known structure and (2) whether its sequence contains the set of residues responsible for a known conformation. Except for L3 in HyHEL-5, all the light-chain regions correspond to a known canonical structure, as do all the H1 regions and the H2 region in HyHEL-10 (Table 1). The conformation predicted for the H2 regions in NC41 and HyHEL-5 was based on the analysis of the H2 region in the preliminary structure of J539 (ref. 8). In all three of these antibodies the H2 region is a four-residue turn with Gly at the fourth position and the predicted conformation is that almost always found for such turns[21]. (Below we present a more accurate analysis of H2 regions.) For H3 regions in HyHEL-5, HyHEL-10, NC41 and NQ10, no prediction of conformation could be made on the basis of the known canonical structures.

The sequences of the VL and VH domains were compared to see which of the known framework structures have sequences close to those of the unknown structures. From the comparisons of the hypervariable and framework regions, one known VL and one known VH structure were taken as the starting points—parents—for the model of the predicted structure. If the conformation predicted for a hypervariable region was not present in the parent, but was present in another known structure, the hypervariable region in the parent was replaced by that in the other structure. Side chains in the parent that were different from those in the unknown structure were replaced[22,23] and the resulting model subjected to a very limited energy refinement[24].



HyHEL-5, HyHEL-10 and NC41 hypervariable regions

The atomic structures of Fab fragments of immunoglobulins HyHEL-5, HyHEL-10 and NC41 in complexes with their protein antigens were determined by X-ray crystallography[16-18]. The resolution of the X-ray data used to determine the structures and value of the residual (R) after refinement are (complex, resolution, R value): HyHEL-5-lysozyme, 2.5 Å, 20%; HyHEL-10-lysozyme, 3.0 Å, 24%; and NC41-neuraminidase, 2.9 Å, 19%. These structures have been determined at medium resolution. The tracing of the polypeptide chain of the hypervariable regions is unambiguous, although the orientation of some of

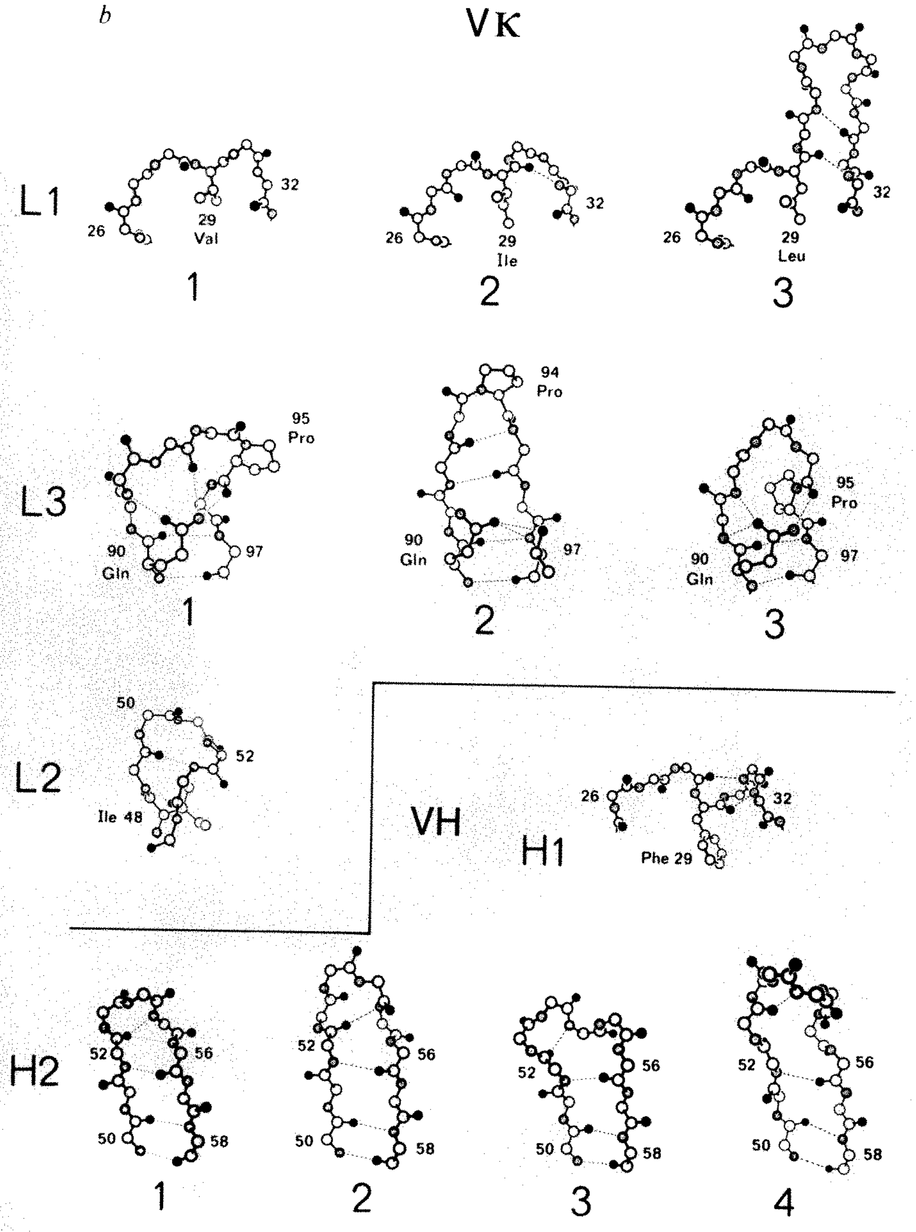


FIG. 1 *a*, Antigen-binding sites of immunoglobulins are formed by six loops of polypeptide, three from the VL domain L1, L2 and L3 and three from the VH domain H1, H2 and H3 (wavy lines). These loops are attached to strands (□) of a conserved β-sheet. *b*, Canonical structures for the hypervariable regions of Vκ and VH domains. In each drawing the region is viewed so that the accessible surface is at top and the framework region below. The main-chain conformation and some of the side chains that determine this conformation are shown. For the definition of the hypervariable regions used here, see Table 1. The immunoglobulins in which the different canonical structures occur are listed in Table 1.

the peptide groups is uncertain. Most side chains are unequivocally placed.

Figure 2 shows the predicted and observed structures of each of the hypervariable regions, superposed by a least-squares fit of their main-chain atoms. Table 2*a* gives, for each predicted and observed hypervariable region, the r.m.s. difference in position of the main-chain atoms.

The main-chain conformations of the predicted and observed hypervariable regions are very similar (Fig. 2, Table 2*a*). The only exception is the H1 region of HyHEL-5. Although the observed and predicted conformations of residues 26-29 and 32 are the same, residues 30 and 31 are in quite different positions. The recently refined structure of Fab J539 (T. N. Bhat, E.A.P. and D.D., manuscript in preparation) shows that these differences were inherited as a result of an error in the original determination of the J539 structure used as the parent for this region. Rebuilding the predicted model with the refined J539 structure puts residues 30 and 31 in the correct position and gives an r.m.s. difference between the predicted and observed H1 regions of 0.6 Å.

Given the medium resolution of the structures used to derive the models and of the experimental structures, the agreement of the predicted and observed loop conformations is excellent.

Relative positions of the hypervariable regions

Figure 3 shows the positions of the hypervariable regions relative to each other and to the framework for the predicted and observed structures. To produce this figure the predicted and observed structures were superposed by a least-squares fit of framework residues. In Table 2*b*, the differences in position of the hypervariable regions are reported.

Small differences in the relative positions of the hypervariable regions in the predicted and observed structures might be expected because of two factors not corrected for in the model building. First, the predicted structures were built using parent V domains that have some residues in the framework and VL-VH interface that are different from those in the final predicted structure. These differences have small but significant effects on the main-chain structure of the individual domains and the way they pack together[2,25,26]. Second, differences between the predicted and observed structures could arise from the effects of the association with the antigen[18]. In other proteins, ligand binding can result in the movement of close-packed segments of polypeptide relative to each other by 1-2 Å, and the ends of loops are able to move somewhat more[27].

The differences in the positions of the predicted and observed H2 regions in HyHEL-5 and NC41 (Table 2*b*) are larger than expected from these factors. The interactions that the H2 regions make with the rest of the VH domain were therefore examined.

Residue 71 and position and conformation of H2

At the same time as the structures of HyHEL-5 and NC41 became available, the refinement of the atomic structure of J539 was completed (T. N. Bhat, E.A.P. and D.D., manuscript in preparation). The conformation of H2 in the refined structure is not like that in HyHEL-5 and NC41 but is the same as that in KOL. This was quite unexpected. The main determinant of the conformation of small turns is usually the position of glycine residues[21]: in KOL, Gly occurs at position 54, and in J539, HyHEL-5 and NC41, Gly occurs at position 55.

An examination of the environments of the H2 regions[28] shows that in KOL and J539 the side chain of framework residue Arg 71 packs between, and forms hydrogen bonds to, H1 and H2. In HyHEL-5, residue 71 is Ala, and here the cavity that would be created by this smaller side chain is filled by the insertion of a residue from the H2 region—Pro 52a. In KOL and J539 the side chain at position 52a is on the surface. The relative movement of position 52a involves a change in the

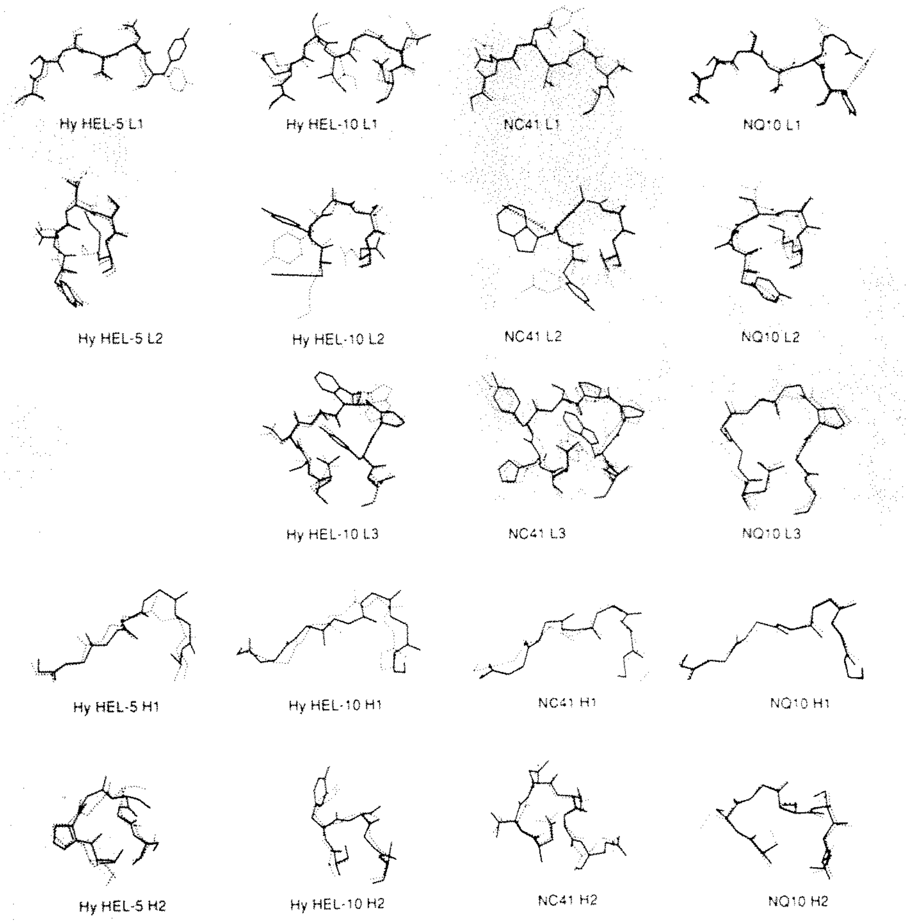

FIG. 2 The predicted (broken line) and observed (continuous line) conformations of the hypervariable regions. The structures have been superposed by a least-squares fit of their main-chain atoms. Residue numbers and the r.m.s. difference in position of the superposed atoms are given in Table 2*a*. Predicted and observed side-chain conformations are shown for all regions except H1 and L3 in NQ10 where they obscure the main chain. After our prediction of the NC41 structure several revisions were made to the sequence and some of the differences can be seen here.

TABLE 2 Differences in structure of predicted and observed hypervariable regions

(*a*) Differences in local conformation (Å)

Hypervariable region	R.m.s. difference in atomic positions of main-chain atoms after optimal superposition			
	HyHEL-5	HyHEL-10	NC41	NQ10
L1:26–32	0.8	1.1	0.7	0.4
L2:49–53	0.9	0.8	0.4	0.9
L3:90–97	—	0.3	0.5	0.6
H1:26–32	1.4	1.3	0.9	0.3
H2:52–56	1.1	1.0	0.7	0.4

(*b*) Differences in position relative to framework (Å)

		Range of differences in positions of C_α atoms after superposition of frameworks residues (Å)	
Protein	Hypervariable region	Original prediction	New structure library
HyHEL-5	L1	2.0–3.8	0.8–2.1
	L2	1.6–1.6	1.2–2.3
	H1	0.8–4.1	0.7–2.1
	H2	3.0–7.2	0.5–2.1
HyHEL-10	L1	0.7–1.6	—
	L2	0.6–.13	—
	L3	0.8–1.5	—
	H1	1.3–3.5	—
	H2	0.6–2.9	—
NC41	L1	1.4–2.4	1.5–2.6
	L2	1.1–1.8	1.0–2.0
	L3	1.6–2.3	1.8–3.0
	H1	1.3–2.0	1.0–2.1
	H2	2.1–4.4	0.4–1.9
NQ10	L1	0.4–2.7	—
	L2	0.5–1.4	—
	L3	0.6–1.5	—
	H1	0.6–1.2	—
	H2	0.6–0.9	—

Superposition of *a* are illustrated in Fig. 2. The differences in the positions of the hypervariable regions in the original predictions and the observed structures of *b* are shown in Fig. 3. The predictions with a new structure library involve rebuilding the HyHEL-5 model using the refined VL J539 and the VH NC41 structures, and rebuilding the NC41 model using VL McPC603 and VH HyHEL-5: see text.

conformation of H2. It also tilts the H2 loop so that the positions of residues at the top of the loop in HyHEL-5 differ in position, relative to those in KOL and J539, by ~4.5 Å. In NC41, the residue at position 71 is Leu and that at position 52a is Thr, and the shift is not as large as that in HyHEL-5.

This analysis implies that the conformation and position of four residue H2 regions are determined by the packing against the VH framework and by the identity of the residue at position 71 in particular, and not by the position in the sequence of H2 of Gly (or Asn or Asp) as was believed previously[8]. Thus VH domains of HyHEL-5 and NC41 should provide better parents for each other than the other structures do, for they contain similar determinants for the position of H2. The predicted structure of HyHEL-5 using the observed structure of VH of NC41 and the predicted structure of NC41 using the observed structure of VH of HyHEL-5 were thus rebuilt. In these new predicted structures the large differences between the predicted and observed positions of H2 are not present: most residues differ by no more than 2.1 Å and none differs by more than 3.0 Å (Table 2*b*).

The results of this analysis were used in the prediction of the structure of the H2 region of the antibody NQ10.

Hypervariable regions of NQ10 and D1.3

The amino-acid sequence of the hypervariable regions and associated framework sites of NQ10 are given in Table 1. For five of the hypervariable regions, the size and the residue conservation at the relevant sites clearly indicate particular canonical structures, and a model of the VL–VH dimer of NQ10 was made using the procedure described above. For H2, after the analysis described above, canonical structure 2 was expecte because of the Arg at position 71 (Table 1).

Recently a crystal structure has been determined for NQ1 (S.S., P.M.A. and R.J.P., manuscript in preparation). This struc ture is determined to a resolution of 2.8 Å and the presen residual is 21%. The tracing of the chain in the hypervariabl regions is unambiguous. Figure 2 shows the predicted an observed structures of each of the hypervariable regions, supe posed by a least-squares fit of their main-chain atoms. Table 2 gives the r.m.s. differences in position of the main-chain atom Figure 3 shows the relative positions of the predicted an observed hypervariable regions.

There is close agreement between the predicted and observe main-chain conformations of the hypervariable regions: th r.m.s. differences in position are between 0.3 and 0.9 Å (Tabl 2*a*). There is also close agreement in the relative positions o the hypervariable regions (Fig. 3 and Table 2*b*). No residue differ by more than 2.7 Å in position and all but two are withi 1.7 Å.

Recently, the atomic structure of antibody D1.3 complexe with lysozyme has been refined[20]. The comparison of the pre liminary experimental structure with the prediction had show differences for two hypervariable regions[9]. The L3 regions ha differences associated with Pro 95 having a *cis*-peptide in th predicted structure and a *trans*-peptide in the observed. The H regions differed because the predicted structure had this regio folded into framework, whereas in the observed it folded ou into the solvent. The refinement of the experimental structur has resulted in the rebuilding of these two regions[20], and thei conformations now agree with the original predictions.

Canonical structures in immunoglobulin 4-4-20

The atomic structure of immunoglobulin 4-4-20 has recentl been determined at a resolution of 2.7 Å (ref. 19). The amino acid sequence of the hypervariable regions and associate framework sites of 4-4-20 are given in Table 1. Four of th hypervariable regions, L2, L3, H1 and H2, have the size an the residues at specific sites that clearly indicate particula canonical structures (see Table 1). These four hypervariabl regions do have the expected main-chain conformations. In Fig 4 the four hypervariable regions, superposed on example of the same canonical structures taken from other immuno globulins, are shown. The r.m.s. difference in the atomi

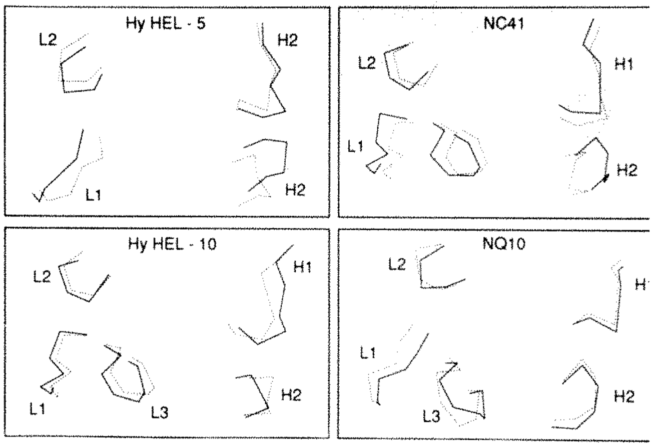

FIG. 3 The relative positions of the hypervariable regions in the predicte and observed structures. The positions of the hypervariable regions show are those given by the superposition of the VL–VH framework regions o the observed and predicted structures. The C_α atoms of residues in th observed structure are joined by solid lines and those in the predicte structure by broken lines. The size of the differences in position are give in Table 2*b*.

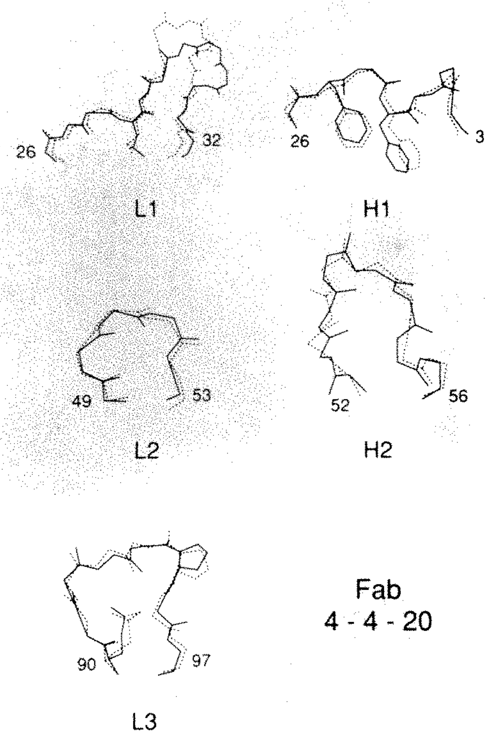

FIG. 4 The hypervariable regions in immunoglobulin 4-4-20. The observed conformations of the hypervariable regions in 4-4-20 are drawn with continuous lines. They are superposed on hypervariable regions from other immunoglobulins that have the same canonical structure—L2 and L3 from REI, H1 from KOL and H2 from McPC603—or in the case of L1, the closely related canonical structure from McPC603. The side chains shown are those that are important in determining the conformation of the region.

position of the main-chain atoms of these pairs are in the range 0.5–0.9 Å.

The L1 region of 4-4-20 has a different size to those found previously and represents a new canonical structure (see Table 1 and Fig. 4). As predicted in a previous discussion of the sequence patterns of this region[8], its conformation is closely related to those of the other canonical structures known for this region. The main-chain atoms of residues 26–31 and 31e–32 fit the same region in McPC603 with a r.m.s. difference in position of 0.8 Å (Fig. 4).

Common occurrence of known canonical structures

The close agreement of the predicted and observed main-chain conformations of the hypervariable regions strongly supports the canonical structure model. It implies that a good estimate can be made of the extent to which hypervariable regions in other immunoglobulins have main-chain conformations close to those that are now known. This can be done by inspecting the known sequences to see whether their hypervariable regions correspond in size to the known canonical structures, and whether they contain one of the sets of residues that produce the observed conformations.

In Table 1 we give the results of examining the immunoglobulin sequences collected by Kabat *et al.*[29]. About 90% of the hypervariable regions in Vκ domains, and ~70% of the H1 and H2 regions in VH domains, are expected to have conformations close to those found in the immunoglobulin structures now known. These estimates are conservative in that they include only hypervariable regions that match the sequence requirements exactly, that is, those that contain the particular residues, or any combination of the small range of closely related residues, that are found in the known structures at the sites marked by asterisks in Table 1.

Discussion

The wide occurrence of the known canonical structures, the use of the much larger library of parent structures that will soon become available, and the more detailed understanding of the determinants of structure that will emerge from the analysis of the differences between predicted and observed structures, should allow, for many immunoglobulins, the prediction of the structure of five of the hypervariable regions with accurate local conformation and errors in position of 2 Å or less.

Predictions of the structures of the H3 regions in the immunoglobulins discussed here could not be made on the basis of the previously known structures. It was possible to predict correctly the H3 conformation in immunoglobulin D1.3 (ref. 9). In general, however, the various genetic mechanisms that produce the H3 regions usually result in medium or large surface loops with very different sequences and patterns of interaction. For such hypervariable regions it may be possible to predict their structure using the conformational search algorithms that have been developed by several groups[30-35].

The results presented here have interesting implications for the molecular mechanisms involved in the generation of antibody diversity. For at least five of the six hypervariable regions of most immunoglobulins there seems to be only a small repertoire of main chain conformations, most of which are known from the set of immunoglobulin structures so far determined. Sequence variations within the hypervariable region modulate the surface that these canonical structures present to the antigens. Sequence variations within the framework and hypervariable regions shift the canonical structures relative to each other by small but significant amounts. □

Reconstitution of active dimeric ribulose bisphosphate carboxylase from an unfolded state depends on two chaperonin proteins and Mg-ATP

Pierre Goloubinoff, John T. Christeller*, Anthony A. Gatenby & George H. Lorimer†

Molecular Biology Division, Central Research & Development Department, E. I. Du Pont de Nemours & Co., Experimental Station, Wilmington, Delaware 19880-0402, USA

In vitro reconstitution of active ribulose bisphosphate carboxylase (Rubisco) from unfolded polypeptides is facilitated by the molecular chaperones: chaperonin-60 from *Escherichia coli* (groEL), yeast mitochondria (hsp60) or chloroplasts (Rubisco subunit-binding protein), together with chaperonin-10 from *E. coli* (groES), and Mg-ATP. Because chaperonins are ubiquitous, a conserved Mg-ATP-dependent mechanism exists that uses the chaperonins to facilitate the folding of some other proteins.

THE chaperonins[1] are a ubiquitous class of proteins implicated in the post-translational folding and assembly of other proteins. They include the groEL or chaperonin-60 (cpn60) and the groES or chaperonin-10 (cpn10) proteins from bacteria[2-4], chloroplasts[5] and mitochondria[6-8]. The earliest evidence for the involvement of the chaperonins with post-translational events was the demonstration that the *E. coli* cpn60 and cpn10 proteins are essential for phage head morphogenesis[9-11]. The chloroplast version of cpn60 is the Rubisco subunit-binding protein, so-called because of its transient association with newly synthesized Rubisco subunits[12-14]. The transient association of newly synthesized unfolded proteins with the chaperonins has also been observed during the formation of pre-beta-lactamase and chloramphenicol acetyltransferase[15] in *E. coli*, during the recombinant expression in *E. coli* of the precursor to the small subunit of Rubisco[16], and also after the import of precursor proteins into yeast mitochondria[17,18] and chloroplasts[19]. But the molecular details of what happens while these polypeptides are associated with the chaperonins remains to be determined.

Recently, we demonstrated *in vivo* that the *E. coli* chaperonins cpn60 and cpn10 promoted the post-translational folding or assembly, or both, of hexadecameric (L_8S_8) and dimeric (L_2) Rubiscos in *E. coli*[20]. We suggested that the chaperonins exert their effect post-translationally, at some point between the unfolded nascent monomer (L) and the formation of the folded dimer (L_2), the basic structural unit of the more complex hexadecamer[21-23]. We have now used the purified *E. coli* chaperonins cpn60 and cpn10 to demonstrate that the *in vitro* reconstitution of the catalytically functional dimeric form of Rubisco from an unfolded biologically inert polypeptide depends on the presence of both chaperonin proteins and Mg-ATP.

The substrate—denatured Rubisco

Rubisco from *Rhodospirillum rubrum* is a dimer of large subunits only[24]. Genetic[25] and structural[21] studies have established that the dimer is the minimal structural entity capable of catalysis, a single active site being composed of amino-acid residues from both subunits.

Because our genetic analysis[20] indicated that the chaperonins functioned post-translationally at some point before the formation of the folded functional dimer, we sought conditions for unfolding native Rubisco in the belief that unfolded Rubisco would serve as a substrate for the chaperonins. To determine the change in secondary structure accompanying the various denaturing regimes, we recorded circular dichroism (CD) spectra in the far ultraviolet range. The spectrum for native decarbamylated Rubisco (Fig. 1, E) showed negative molar ellipticity ($\theta_{220} = -10^4$ degrees · cm^2 · dmol^{-1}) that is expected for a protein with this structure. On denaturation with either 8 M

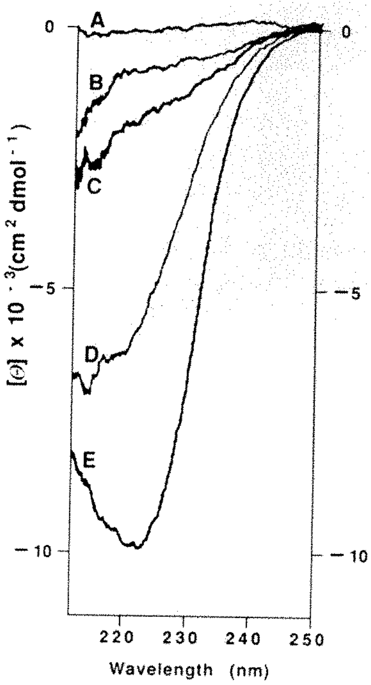

FIG. 1 CD spectra of native and denatured Rubiscos. † To whom correspondence should be addressed.

urea (Fig. 1, C) or 6 M guanidine-HCl (Fig. 1, B), the negative ellipticity was strongly reduced indicating a considerable loss of secondary structure. We conclude that treatment with either 8 M urea or 6 M guanidine-HCl converts Rubisco into unfolded monomeric polypeptides. We refer to Rubisco in this state as Rubisco-U.

Treatment of Rubisco with acid (pH 3) led to a rapid ($t_{1/2} \sim$ 30 s) loss of activity which was not recovered on neutralization. The CD spectrum of acid-denatured Rubisco (Fig. 1, D) showed some reduction of the negative band ($\theta_{220} = -6 \times 10^3$ degrees·cm^2·dmol^{-1}). It is evident, however, that much secondary structure remains under these conditions. Whether or not the structure of the acid-denatured Rubisco corresponds to the molten-globule or A-state, observed with other proteins[26-28] at acidic pH, requires further investigation. We refer to acid-denatured Rubisco in this partly unfolded state as Rubisco-A.

Chaperonin-dependent Rubisco reconstitution

Attempts to spontaneously reconstitute active Rubisco from both Rubisco-U and Rubisco-A under various conditions were unsuccessful. By contrast, when either Rubisco-U or Rubisco-A was diluted into solutions containing both chaperonins cpn60 and cpn10, and Mg-ATP, Rubisco activity, indicative of a folded dimer, was reconstituted (Fig. 2*a*). No reconstitution occurred when cpn60 or cpn10 was omitted. The time course of reconstitution was followed by using a glucose-hexokinase quench, demonstrating the requirement for Mg-ATP (Fig. 2*a*, *b*). The maximum reconstitution was ~80%. Rubisco-U consistently yielded the greatest quantity of reconstituted enzyme. Rubisco-A was reconstituted to ~40% (Fig. 2*a*). Although the extent of reconstitution varied, depending on whether Rubisco-U or Rubisco-A was used as substrate, the rate constant for the chaperonin-dependent reconstitution was the same, within the limit of experimental error. This implies that reconstitution involves a common intermediate, the formation of which preceeds the same chaperonin-dependent rate-determining step. We propose that on removal of the denaturant by dilution, a rapid chaperonin-independent folding of Rubisco-U to a state rich in secondary structure and resembling Rubisco-A (Rubisco-I state), is followed by reaction with cpn60, cpn10 and Mg-ATP.

Reconstitution of Rubisco involves two processes. Folding of the polypeptide, which is independent of concentration, followed by the assembly of the folded but inactive monomers into catalytically competent dimers. Assembly depends on the concentration of monomers and on the dissociation constant governing their interaction. The magnitude of this dissociation constant is so far unknown. We anticipated that the appearance of Rubisco activity might, however, be preceded by a lag period, during which sufficient folded monomers accumulate before dimerization. Inspection of the earliest part of the reconstitution (Fig. 2*b*) revealed just such a lag. We estimate that detectable dimer formation requires the accumulation of ~2 nM folded monomers. A similar value was computed after the synthesis of Rubisco in a prokaryotic cell-free transcription–translation system[29].

The chaperonin-dependent reconstitution system was examined as a function of the concentrations of Rubisco, cpn60 and cpn10, varying the concentration of one component at a time (Fig. 3). First, no reconstitution occurred when either cpn10 (Fig. 3*a*) or cpn60 (Fig. 3*b*) was omitted. Second, optimal reconstitution occurred when cpn60 and cpn10 were approximately equimolar (Fig. 3*a*, *b*). Note, however, that reconstitution was inhibited when the concentration of cpn60 exceeded that of cpn10 (Fig. 3*b*).

The dependency of the reconstitution system on the Rubisco concentration was more complex (Fig. 3*c*) and reflected the interplay of two processes. At the lowest concentration of Rubisco used (3 nM protomer), only 20% reconstitution occurred. But the yield of active enzyme increased with increas-

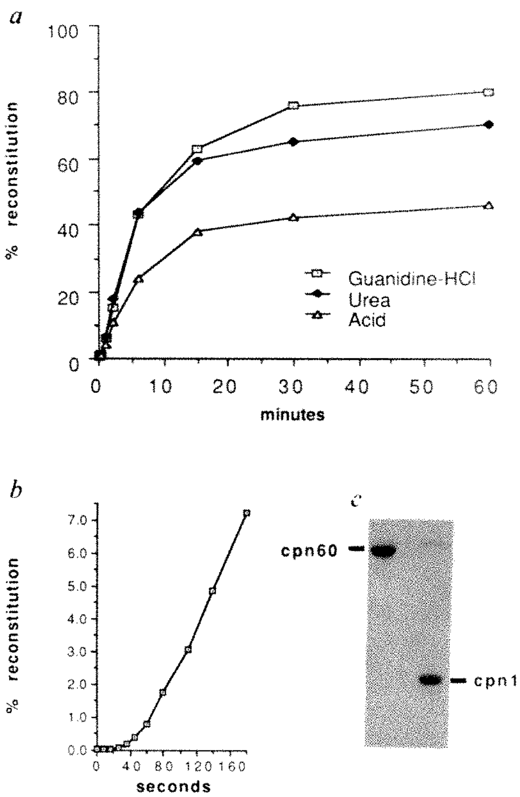

FIG. 2 The time-course of chaperonin- and Mg-ATP-dependent reconstitution of active Rubisco from variously denatured Rubiscos (Rubisco-U or Rubisco-A). *a*, Complete time courses of reconstitution. *b*, Lag in the formation of active Rubisco dimers from a different experiment to that represented in *a*. In both cases Rubisco activity is expressed as a percentage of the activity of an equal quantity of native non-denatured enzyme. *c*, SDS-PAGE of the purified preparations of cpn60 and cpn10 from *E. coli* used in this study. METHODS. The *E. coli* chaperonins cpn60 and cpn10 were purified from lysates of cells bearing the multicopy plasmid pGroESL[20], by modifications (to be described elsewhere) of published purification protocols[30,38]. Recombinant dimeric Rubisco was purified from *E. coli* expressing a plasmid-encoded gene from *R. rubrum* as previously described[39,40]. *a*, Rubisco-U was prepared by incubating 15.4 μM Rubisco (protomer) in 0.1 M Tris–HCl buffer, 0.01 M EDTA, pH 7.7, containing either 5.7 M guanidine-HCl or 7.6 M urea for 2 h at 25 °C. Rubisco-A was prepared by incubating 15.4 μM Rubisco (protomer) in 50 mM glycine-HCl, pH 3.0, for 210 s at 25 °C. Reconstitution was initiated by diluting 6.7 μl of the denatured Rubisco-U or Rubisco-A into 1,418 μl solution containing 50 mM Tris–HCl buffer, pH 7.5, 2 mM ATP, 12 mM $MgCl_2$, 10 mM glucose, 4.3 μM cpn60 (protomer) and 9.6 μM cpn10 (protomer) at 25 °C. The final concentration of Rubisco protomer in the reconstitution reaction was 72 nM. At the times indicated a 150 μl aliquot was withdrawn and added to 10 μl solution containing 6 U of hexokinase so as to arrest the reconstitution reaction. After the last aliquot had been withdrawn, the reaction mixtures were supplemented with 50 mM $[^{14}C]NaHCO_3$ (300 d.p.m. nmol^{-1}) and allowed to activate for a further 5 min. Ribulose bisphosphate (1 mM) was added and Rubisco activity measured as the formation of acid-stable ^{14}C over 30 min at 25 °C. The activity of native Rubisco (100%) under these conditions was 2.7 s^{-1}. *b*, Rubisco-U (20.4 μM protomer) was prepared in guanidine-HCl as described above. Reconstitution was initiated by diluting 21 μl Rubisco-U into 1,659 μl solution containing 50 mM Tris–HCl buffer, pH 8.0, 3 mM ATP, 7 mM $MgCl_2$, 20 mM glucose, 4 μM cpn60 (protomer) and 6 μM cpn10 (protomer) at 23 °C. At the times indicated, the reconstitution reaction was quenched with hexokinase and Rubisco activity determined as described above. *c*, Samples of purified cpn60 and cpn10 containing ~4 μg were boiled in 1% SDS for 5 min and applied to a 16% SDS-polyacrylamide gel. After electrophoresis, the gel was stained with Coomassie blue.

ing concentration until an optimum (for this particular concentration of chaperonins) was reached at ~50 nM Rubisco. These results are again consistent with the need to accumulate sufficient folded monomers to drive the assembly of active dimers. Optimal reconstitution was reached at a cpn60 : Rubisco-protomer concentration ratio of ~50:1 (Fig. 3*c*). But because reconstitution involved the oligomeric form of cpn60, the double-doughnut-shaped 14-mer[30,31] ($[\text{cpn60}]_{14}$) (Fig. 4, B and C), the molar ratio of $[\text{cpn60}]_{14}$ to Rubisco protomers was closer to 3:1. The requirement for excess cpn60 over Rubisco was largely due to the instability of the partly folded intermediate, Rubisco-I, that is believed to be generated from both Rubisco-U and Rubisco-A on removal of the denaturant, and its propensity to irreversibly aggregate (Fig. 4). The decline in the yield of reconstituted Rubisco observed as the concentration of Rubisco-U was increased was due to irreversible aggregation (Fig. 3*c*). Thus, when either Rubisco-U or Rubisco-A was diluted into solutions containing the chaperonins, two competitive and mutually exclusive processes occurred. The unfolded or partly folded protomers either formed biologically unproductive aggregates or they formed a binary complex with $[\text{cpn60}]_{14}$ (see below), which prevented aggregation and directed the protomers along a biologically productive pathway.

Homologous cpn60s also support reconstitution

The prokaryotic cpn60 is homologous to the eukaryotic chaperonins hsp60, from yeast mitochondria, and the Rubisco subunit-binding protein, from plant chloroplasts[5,7]. We purified both proteins to homogeneity and used them in a heterologous reconstitution system with *E. coli* cpn10. We used approximately equal concentrations of each of the cpn60 proteins together with equal concentrations of cpn10. The heterologous chaperonin combinations cpn60 (yeast)-cpn10 (*E. coli*), and cpn60 (chloroplast)-cpn10 (*E. coli*) were respectively 10% and 25% as effective as the homologous cpn60–cpn10 (*E. coli*) combination in facilitating the reconstitution of Rubisco-U. This was not unexpected, because the chaperonins of a given organism have presumably evolved to function together.

Cpn60 traps an unstable folding intermediate

Evidence that Rubisco-U is rapidly converted to an unstable intermediate state, Rubisco-I, on removal of the denaturant, and the ability of cpn60 to stabilize this intermediate was provided by the delay experiment, the results of which are shown in Fig. 4. In this experiment, Rubisco-U was diluted into a solution lacking cpn60. Cpn60 was added 5–60 s later. Cpn10 was added ~10 min later to complete the reconstitution mixture. The ability of the chaperonins to reconstitute activity from Rubisco-U was rapidly lost as the time between the dilution of Rubisco-U and the addition of cpn60 increased. The rate at which recoverable activity was lost increased as the concentration of Rubisco protomers increased (Fig. 4), indicating that an unstable folding intermediate—Rubisco-I, formed from Rubisco-U on dilution—was susceptible to irreversible aggregation. This accounts for the progressive decline in the yield of reconstituted Rubisco observed as the concentration of Rubisco-U introduced into the system was increased (Fig. 3*c*). We conclude that when Rubisco-U is diluted into solutions containing the chaperonins, two competitive and mutually exclusive processes occur—aggregation or formation of a binary complex with $[\text{cpn60}]_{14}$.

Rubisco-I–$[\text{cpn60}]_{14}$ binary complex is stable

We demonstrated the physical existence of a stable binary complex between Rubisco-I and cpn60, and the conditions leading to the formation of an active dimer of Rubisco, by immunoelectrophoretic procedures (Fig. 5). When Rubisco-U was diluted into a solution containing cpn60, cpn10 and Mg-ATP, Rubisco activity, indicative of folded dimers, was reconstituted (Fig. 5*a*, column 7). The dimer was detected immunochemically after non-denaturing PAGE (Fig. 5*b*, track 7). When one or more of the components was omitted, or when the chaperonins were first boiled, no reconstitution of Rubisco activity occurred (Fig. 5*a*, columns 2–6, 8 and 9, respectively) and no cross-reactive band corresponding to the dimer was detected (Fig. 5*b*, tracks 2–6, and 8 and 9, respectively). In the presence of native cpn60, but when either cpn10 or Mg-ATP or both were absent,

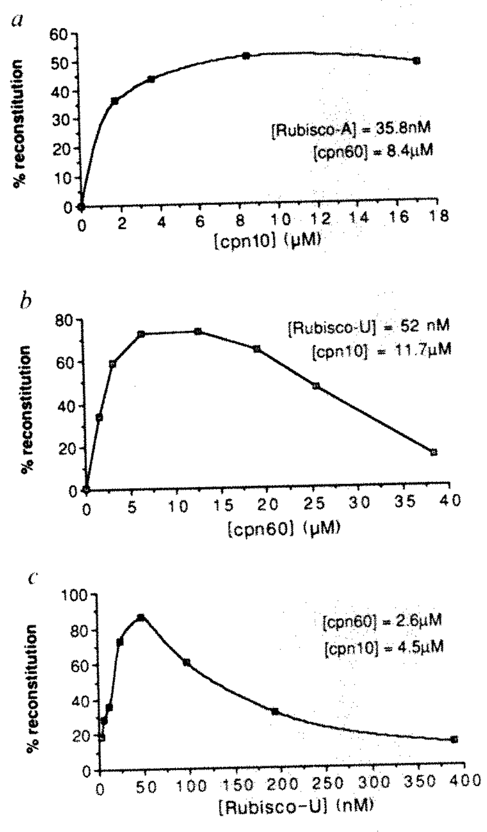

FIG. 3 The chaperonin- and Mg-ATP-dependent reconstitution of active Rubisco as a function of the concentrations of Rubisco, cpn60 and cpn10. The yield of reconstituted Rubisco as function of variable cpn10 concentration, as indicated, constant cpn60 concentration, constant Rubisco concentration (*a*); variable cpn60 concentration as indicated, constant cpn10 concentration, constant Rubisco concentration (*b*); variable Rubisco concentration as indicated, constant cpn60 concentration, constant cpn10 concentration (*c*). Note that these are not measurements of the initial rates of reconstitution, but the extent of complete reconstitution after 1–3 h.

METHODS. *a*, Rubisco-A was prepared by incubating 1.8 mM Rubisco (protomer) in 50 mM glycine-HCl, pH 3.0, for 4 min at 23 °C. Reconstitution was initiated by diluting 5 μl Rubisco-A into 245 μl solution containing 75 mM Tris–HCl buffer, pH 7.7, 7.5 mM $MgCl_2$, 5 mM ATP, 1 mg ml^{-1} BSA, 8.4 μM cpn60 (protomer) and various concentrations (0–17.8 μM protomer) of cpn10. A control containing an equal quantity of native Rubisco was also prepared. After incubation for 1 h at 23 °C, Rubisco activity was determined as described in the legend to Fig. 2. *b*, Rubisco-U (3.9 μM protomer) was prepared as described above. Reconstitution was initiated by diluting 4 μl Rubisco-U (3.9 μM) into 296 μl solution containing 11.7 μM cpn10 (protomer), 50 mM Tris–HCl buffer, pH 8.0, 15 mM $MgCl_2$, 4 mM ATP and various concentrations (0–38.4 μM protomer) of cpn60. Controls containing an equal quantity of native Rubisco were prepared. After incubation at 25 °C for 1 h, Rubisco activity was determined as described in the legend to Fig. 2. *c*, Various concentrations (0.31 to 39 μM protomer) of denatured Rubisco-U were prepared by incubating the appropriate amount of Rubisco in 5.7 M guanidine-HCl, 0.1 M Tris–HCl buffer, pH 7.7, 0.01 M EDTA for 1 h at 23 °C. Reconstitution was initiated by diluting 2.5 μl Rubisco-U into 247.5 μl solution containing 2.6 μM cpn60 (protomer), 4.5 μM cpn10 (protomer), 2 mM ATP, 12.5 mM $MgCl_2$ and 75 mM Tris–HCl buffer, pH 7.8. Controls using the same quantity of native Rubisco were prepared. After incubation for 3 h at 25 °C, Rubisco activity was determined as in the legend to Fig. 2, with the exception that the duration of the Rubisco assay was varied according to the quantity of enzyme present.

two electrophoretically distinct immunochemically cross-reactive signals were observed (Fig. 5*b*, tracks 3, 4 and 6). The first sharply defined band, revealed with antibody against Rubisco, corresponded to the binary complex of Rubisco subunits bound to the oligomeric form $[\text{cpn60}]_{14}$. The same oligomer of cpn60, whether or not associated with Rubisco-I, was also revealed with antibody against cpn60 (Fig. 5*c*, tracks 1, 3, 4, 6 and 7).

The second cross-reactive signal revealed with antibody against Rubisco, represented a poorly defined smear of Rubisco subunits with a slower electrophoretic mobility than the dimer (Fig. 5*b*, tracks 3, 4 and 6). The nature of these soluble Rubisco subunits is puzzling. They have no catalytic activity. Perhaps they are misfolded or partly folded monomers which arise during electrophoresis by dissociation of the binary complex.

The binary complex could also be demonstrated starting with acid-denatured Rubisco-A (data not shown). Therefore, we conclude that a common folding intermediate, Rubisco-I, is generated from both Rubisco-U and Rubisco-A on dilution, and that Rubisco-I is stabilized by forming a binary complex with $[\text{cpn60}]_{14}$. Because Rubisco-A, and by inference Rubisco-I, has significant secondary structure (Fig. 1), it follows that considerable folding of Rubisco-U to the state represented by Rubisco-I must occur before interaction with cpn60.

The experiment represented in Fig. 5 provided further insight into the mechanism of the chaperonin-dependent reconstitution reaction. First, note that native Rubisco showed no detectable interaction with cpn60 (Fig. 5*b*, *c*; tracks 1 and 10). In the absence of Mg-ATP, cpn60 moved electrophoretically on non-denaturing gels as a single oligomeric species of high relative molecular mass, $[\text{cpn60}]_{14}$ (refs 30 and 32). In the presence of Mg-ATP, however, dissociation of $[\text{cpn60}]_{14}$ to a species of lower relative molecular mass occurred, and a second band, designated $[\text{cpn60}]_n$, appeared on the western blot (Fig. 5*c*, tracks 1, 4, and 7–9). The number of cpn60 subunits in $[\text{cpn60}]_n$ is not known. The chloroplast cpn60, the Rubisco subunit-binding protein, has been reported to behave similarly[13,32]. Although the addition of Mg-ATP to the mixture of the binary complex and uncomplexed $[\text{cpn60}]_{14}$ caused the formation of a smaller species of cpn60, Mg-ATP alone did not lead to the formation of active Rubisco (Fig. 5*a*, column 4), nor to the discharge of the binary complex (Fig. 5*b*, track 4). Similarly, the addition of cpn10 alone led neither to the formation of active Rubisco (Fig. 5*a*, column 6) nor to the discharge of the binary complex (Fig. 5*b*, track 6). Only when both cpn10 and Mg-ATP were added was the binary complex discharged with the

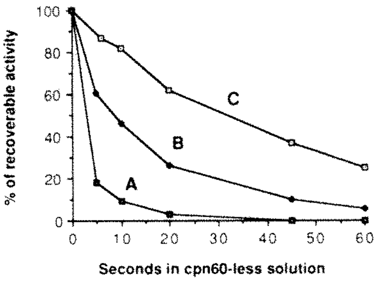

FIG. 4 The instability of the folding intermediate $[\text{Rubisco-I}]_1$ in the absence of cpn60 and the concentration dependence of its decay–aggregation. Rubisco-U 109 nM protomer (A), 54.3 nM protomer (B) or 27.2 nM protomer (C) was incubated in solutions not containing cpn60 (cpn60-less solutions) for the indicated times, when cpn60 was added to stabilize the folding intermediate $[\text{Rubisco-I}]_1$.

METHODS. Rubisco-U at three different concentrations (10.9 μM, 5.4 μM and 2.7 μM protomer) was prepared in 5.7 M guanidine-HCl, 0.1 M Tris-HCl buffer, pH 7.7, 1 mM dithiothreitol and 0.1 mM EDTA. At time zero, 50-μl aliquots of Rubisco-U were diluted into 950 μl solution containing 50 mM Tris-HCl buffer, pH 8.0, 0.5 mg ml^{-1} BSA, 15 mM $MgCl_2$, and 5 mM ATP at 23 °C. At the times indicated, 50-μl aliquots were withdrawn and added to 250 μl solution containing 50 mM Tris-HCl buffer, pH 8.0, 15 mM $MgCl_2$, 5 mM ATP and 6.3 μM cpn60 (protomer) so as to give the following concentrations of Rubisco protomer: 109 nM (A), 54.3 nM (B) and 27.2 nM (C). About 10 min after the last aliquot had been withdrawn, 6 μl cpn10 (protomer; 145 μM) were added to initiate reconstitution. After 1 h at 25 °C, Rubisco activity was determined as described in the legend to Fig. 2. For the time-zero points, 2.5 μl Rubisco-U were diluted directly into 297.5 μl cpn10-less reconstitution mixture. Subsequent treatment was as described above. Controls using equal quantities of native Rubisco were prepared. The data are normalized to the time-zero points for each concentration of Rubisco-U.

FIG. 5 Chaperonin- and Mg-ATP-dependent reconstitution of active dimeric Rubisco from denatured Rubisco-U. *a*, Rubisco activity, expressed as a percentage of the activity observed with an equal quantity of non-denatured, native Rubisco. *b*, Western blot after non-denaturing PAGE of the reaction mixtures used in *a* and probed with antibody (Ab) raised against Rubisco. The positions of $[\text{cpn60}]_{14}$ and of native Rubisco are indicated. The binary complex of $[\text{cpn60}]_{14}$-Rubisco was not resolved from uncomplexed $[\text{cpn60}]_{14}$. Note the association of Rubisco with $[\text{cpn60}]_{14}$ in tracks 3, 4 and 6. The achromic band in the middle of the native Rubisco bands in tracks 1 and 7 is due to cpn10, which interferes with the interaction of Rubisco and its antibody. *c*, As in *b*, but probed with antibody raised against cpn60. Note the dissociation of $[\text{cpn60}]_{14}$ to a lower relative molecular mass species, $[\text{cpn60}]_n$, in the presence of Mg-ATP. *d*, Summary of the reaction conditions.

METHODS: Denatured Rubisco-U was prepared by incubating 15.4 μM Rubisco (protomer) in 5.7 M guanidine-HCl, 0.1 M Tris-HCl buffer, pH 7.7, 1 mM dithiothreitol and 0.1 mM EDTA for 3 h at 25 °C. Reconstitution was initiated by diluting 2.5 μl above solution into 247.5 μl solution containing (when complete) 50 mM Tris-HCl buffer, pH 7.7, 4.0 mM ATP, 12 mM $MgCl_2$, 1 mM dithiothreitol, 4.0 μM cpn60 (protomer) and 7.6 μM cpn10 (protomer). Individual components were omitted as indicated in *d*. When chaperonins were omitted (as in tracks 2–5 and 10), an equivalent molar concentration of BSA was added. Boiled (100 °C, 10 min) chaperonins were added as indicated (tracks 8 and 9). Controls employing an equal concentration of native Rubisco (tracks 1 and 10) were prepared. Alternatively, after the period for reconstitution, aliquots of the reaction mixtures were analysed by non-denaturing PAGE on 6.5% gels, followed by immunodetection using antibodies raised against either Rubisco (*b*) or cpn60 (*c*). To suppress the nonspecific binding of anti-Rubisco antibodies to cpn60 in *b*, 15 μg/ml^{-1} purified cpn60 was added to the 5% milk-blocking mixture.

appearance of the native dimer (Fig. 5*b*, track 7) and of Rubisco activity (Fig. 5*a*, column 7). From these experiments we conclude that the chaperonin-dependent reconstitution of Rubisco involves a strictly ordered set of reactions—first, the formation of a stable bindary complex of $[\text{cpn60}]_{14}$-$[\text{Rubisco-I}]_1$, which at least *in vitro* can be demonstrated as an Mg-ATP- and cpn10-independent event, followed by the Mg-ATP- and cpn10-dependent discharge of folded and stable, but catalytically inactive, monomers, which subsequently assemble into active dimers.

Cpn10 and ATP react with the binary complex

We determined the initial rate of reconstitution as a function of the concentration of Mg-ATP. On this basis the Michaelis constant K_m for Mg-ATP was ~0.3 mM (data not shown). Other nucleotide triphosphates (CTP, GTP, UTP and dATP) were investigated for their ability to support reconstitution. Rubisco activity was determined after one hour's incubation in the presence of cpn60, cpn10 and 5 mM nucleotide triphosphate. No reconstitution was seen with GTP, UTP and dATP. But CTP supported a chaperonin-dependent reconstitution of Rubisco activity, with a yield of ~50%. Non-hydrolysable analogues of ATP (α,β-methylene adenosine 5′-triphosphate, β,γ-methylene adenosine 5′-triphosphate and β,γ-imidoadenosine-5′-triphosphate) did not support reconstitution. Nor did adenosine 5′-(γ-thio)triphosphate support reconstitution. Furthermore, adenosine 5′-(γ-thio) triphosphate inhibited the ATP-dependent reconstitution reaction (data not shown), indicating that at least this ATP-analogue can bind to the chaperonin protein. The failure of these ATP analogues to support the chaperonin-dependent reconstitution of Rubisco indicates that the hydrolysis of ATP could be involved.

Discussion

The essential function of the chaperone proteins, as proposed by Pelham[33], and by Ellis and colleagues[1,34], is to facilitate the folding of other polypeptides and their assembly into oligomeric structures of which they are not a part. It was further proposed that molecular chaperones both prevent the formation of incorrect structures and unscramble those that do occur. The experiments reported here provide experimental evidence both for and against the three elements of this hypothesis. First, the *E. coli* chaperonins cpn60 and cpn10 facilitate a Mg-ATP-dependent conversion of an unfolded or partly folded polypeptide—Rubisco in this instance—into a correctly folded catalytically active dimer, in accordance with the main postulate. Second, the folding of Rubisco involves an unstable intermediate, Rubisco-I, with a propensity to aggregate to form biologically unproductive structures. By forming a stable binary complex with cpn60, the formation of these incorrect structures is prevented and the folding intermediate directed down a biologically productive pathway. But the chaperonins are unable to rescue Rubisco molecules which aggregate. This step seems irreversible, at least on the timescale of our experiments.

The failure of both Rubisco-U and Rubisco-A to fold spontaneously under the conditions we have used and within the time frame of the experiments described here does not exclude the possibility that they could be induced to do so under a different set of conditions. But regardless of that, we are left with the fact that the chaperonins enhance the rate of reconstitution of Rubisco under the chosen conditions by a very substantial factor. Therefore, along with *cis-trans* prolyl isomerase[35,36] and protein disulphide isomerase[37], the chaperonins accelerate the rate of folding of other proteins. Unlike *cis-trans* prolyl isomerase and protein disulphide isomerase, whose molecular mechanisms are understood in principle, if not in detail, however, the molecular basis for the rate enhancement observed with the chaperonins is at the moment obscure.

The chaperonin-facilitated reconstitution of Rubisco activity involves two steps—a folding step, followed by the assembly of two folded but catalytically inactive monomers into a catalytically active dimer. The results presented here are consistent with the notion that the chaperonins facilitate at least some part of the folding step, with assembly of the dimer occurring subsequently and independently of the chaperonins.

The requirement for a large molar excess of chaperonin over the substrate Rubisco-U or Rubisco-A (Fig. 3) is largely due to the unstable nature of the folding intermediate Rubisco-I, generated on diluting Rubisco-U or Rubisco-A into the reaction solution. It is clear from Fig. 4 that the concept of a stable substrate 'patiently' awaiting interaction with sub-stoichiometric quantities of a catalyst does not apply here. Instead, there is an urgent need to stabilize this fickle intermediate by formation of a binary complex with cpn60. A large excess of cpn60 assures the formation of the stable biologically productive binary complex. The need to sequester unstable folding intermediates evidently exists *in vivo* as well as *in vitro*. The formation of a binary complex between the Rubisco large subunit and chloroplast cpn60 was demonstrated long ago[41,42]. The molar ratio of cpn60 to newly synthesized subunits of Rubisco *in vivo* is also very large[12,13].

The molecular details of what happens to Rubisco while it is associated with the cpn60, and the mechanism by which cpn10 and Mg-ATP facilitate the discharge of the binary complex leading to the formation of active Rubisco, are the least understood aspects of chaperonin function. The hydrolysis of ATP seems to be necessary, because non-hydrolysable analogues of ATP do not support reconstitution. Although the stoichiometry of the reaction is unknown, it is unlikely that the chaperonin system is thermodynamically coupled, with the energy released on hydrolysis of ATP being conserved in the folded native state. Instead, we favour the notion that the hydrolysis of ATP serves some regulatory function and that the energy is ultimately dissipated as heat.

The *E. coli* chaperonins clearly did not evolve to facilitate the folding or assembly, or both, of Rubisco, a protein not normally found in *E. coli*. It follows that the interaction between cpn60 and the partly folded Rubisco cannot be specific for Rubisco alone. Instead, the specificity of the interaction must lie in some so far undefined structural element of the partly folded protein. Because the native protein shows no detectable interaction with cpn60, this structural element must be missing altogether from, or inaccessible in, the native protein. The solution to the problems of substrate specificity and reaction stoichiometry, and to the many other questions raised by this study, await further investigation. □

Lunar basalt breccia identified among Antarctic meteorites

Jeremy S. Delaney

Department of Geological Sciences, Rutgers University, New Brunswick, New Jersey 08903, USA

THE Antarctic meteorite Elephant Moraine (EET) 87521 is a lunar mare basalt breccia. This 30.7-g meteorite was originally identified as a brecciated eucrite[1], but new petrographic evidence from a more representative thin section (Fig. 1) indicates that it is a breccia of mainly very-low-titanium (VLT) basalt, and should be reclassified as a lunar meteorite. The four (or five) Antarctic lunar meteorites collected previously at Allan Hills, Yamato Mountains and MacAlpine Hills (ALHA81005, Y79117/Y793274, Y82192/82193+/−Y86032(?) and MAC88104/88105) have all sampled only the plagioclase-rich lunar highlands[2,3] which dominate the surface of the Moon. EET87521 extends the lunar meteorite collections to include the less abundant basaltic provinces (the maria) of the lunar crust.

Meteorite EET87521 contains lithic and mineral clasts in a matrix of fine-grained breccia and glass. The modal mineralogy, determined from 900 random microprobe analyses of thin section, 87521, 8 (area ~90 mm^2) is: 10% olivine (Fo_{62}–Fo_3; Fo, forsterite); 47% subcalcic augite and augite with Mg/(Mg+Fe) ratios between 0.65 and 0.2 (Fig. 2); 38% calcic plagioclase (An_{68}–An_{95}; An, anorthite)[1]; 4% silica minerals; 1% of ilmenite, chromite, titanium-rich chromite and sulphide. This mineralogy is comparable with many mare basalts[4]. Representative compositions of most minerals are given in Table 1. An estimate of the bulk composition derived from the modal abundance and the mean compositions of the phases present is: 47% SiO_2, <0.8% TiO_2, 11.6% Al_2O_3, <0.4% Cr_2O_3, 19.5% FeO, 0.3% MnO, 8.8% MgO, 10.1% CaO, 0.3% Na_2O, ~100 p.p.m. K_2O (ref. 5). These data are consistent with derivation from a mare basalt source. On the basis of instrumental neutron activation analysis (INAA) data[6], EET87521, 6 seems to contain lunar highlands material, represented by higher normative plagioclase and Mg/(Mg+Fe). The meteorite's oxygen isotope signature[7] is consistent with a lunar origin ($\delta^{18}O = 5.4$, where $\delta^{18}O = ((^{18}O/^{17}O)_{\text{sample}}/(^{18}O/^{17}O)_{\text{standard}}) - 1$; $\delta^{17}O = 2.8$; R. N. Clayton and T. K. Mayeda, personal communication).

The lithic clasts in EET87521, 8 range from a 5-mm, fairly coarse-grained gabbroic fragment with fayalite, iron-rich augite, plagioclase and various oxides (Fig. 1) to small fine-grained graphic intergrowths of augite, fayalite and silica in ilmenite. Magnesian components (Mg/Mg+Fe of 0.65–0.5) are less common (Fig. 2*a*) and occur almost exclusively as mineral clasts. All the plagioclase and pyroxene is shocked. The presence of shock glass indicates pressures in excess of 30 GPa but the plagioclase has generally not been maskelynitized (that is, transformed to a glass by shock pressures in excess of 25 GPa). The textures of the lithic clasts indicate that the sample was shocked to less than the 25–30 GPa necessary[8] for maskelynitization and was invaded by shock glass, perhaps at the time of ejection into an Earth-intercepting trajectory.

The mineralogy of EET87521 differs from the basaltic achondrites with which it was originally identified[1], as it contains much more modal olivine and has abundant subcalcic augite and augite, in addition to pigeonite. The range of mineral compositions is similar to that seen in the polymict achondrites but the Fe/Mn ratios of the mafic minerals (90–100 in olivine and 60–80 in pyroxene) are much higher than those from achondrites (30–53 in olivine and 25–40 in pyroxene[9]). The Fe/Mn

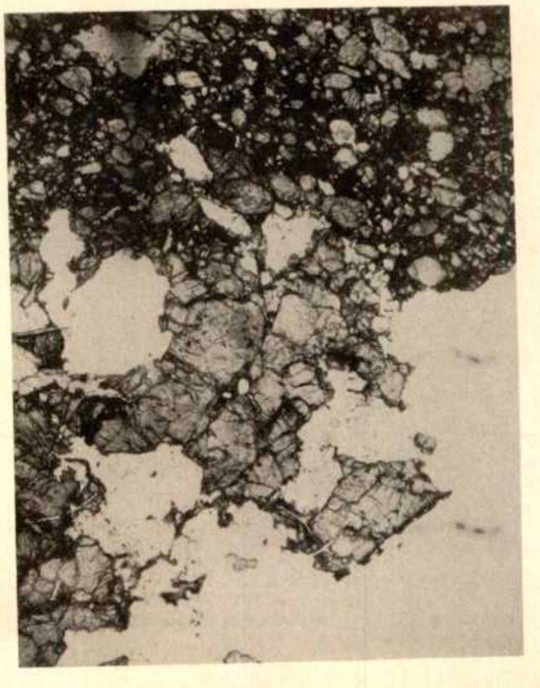

FIG. 1 Augite- and olivine-rich mafic clast and surrounding breccia in meteorite Elephant Moraine 87521, 8, a very-low-titanium basalt breccia. Thin veins of shock glass crosscut both the plagioclase and augite in the lithic clast. Long dimension is ~4 mm, plane-polarized light.

ratios are typical of Apollo and Luna samples and probably of much of the lunar crust. The estimate of the bulk composition resembles the Apollo 17 VLT and Luna 24 VLT basalts[10] but has a low Mg/(Mg+Fe) ratio. The abundant fayalitic olivine in the lithic clasts also shows that this meteorite contains highly fractionated basalts. The incompatible element content (Na and K) seems low in 87521, 8 but rare-earth-element abundances in 87521, 6 (ref. 6) are fairly high and are consistent with a fractionated source.

The number of lunar meteorites from the highlands (four or possibly five) and from the maria (one) matches fairly well with the relative areas of these provinces (83% highlands and 17% maria) on the Moon[11]. The number of samples is small, but this correspondence suggests that impacts on the Moon that are large enough to propel samples to the Earth have been sufficiently frequent to ensure representative random sampling of the lunar crust. The present lunar meteorite suite is a less biased sampling of the entire lunar crust than the combined Apollo and Luna suites, which together enclose <5% of the surface area of the moon[11]. The absence of precise locality information for the lunar meteorites restricts the interpretation of the data, but as samples for testing the generality of models based on the Apollo and Luna suites, they assume enormous importance. Random sampling of the lunar surface by meteorites also implies that two or three of the highlands meteorites are from far-side sites. □

ONE of the main families of oxide superconductors comprises compounds with varying numbers of CuO_2 sheets sandwiched between BiO or TlO bilayers[1–5]. The superconducting transition temperature (T_c) in these compounds increases with the number of CuO_2 sheets; for example, T_c is 80–108 K for the double-sheet 2212 phase, and 110–125 K for the triple-sheet 2223 phase. Here we describe a new family of double-sheet copper oxide compounds with BiO or TlO bilayers, which can improve our understanding of the relationship between T_c and the CuO_2 sheets. The new compounds, $Bi_2Sr_2(Ln_{1-x}Ce_x)_2Cu_2O_{10+y}$ and $Tl_2Ba_2(Ln_{1-x}Ce_x)_2Cu_2O_{10+y}$ (where Ln is Sm, Eu or Gd), have double CuO_2 pyramidal sheets between double BiO or TlO layered units, like the 2212 phase, but with a different arrangement of adjacent CuO_2 sheets. The new bismuth compounds (Bi-2222) have a significantly

lower T_c (~30 K or less) than the 2212 or 2223 phases, even when the charge-carrier (hole) concentrations are comparable. So far, we have not found superconductivity in the Tl-2222 compounds.

We synthesized the materials by solid-state reaction. For the bismuth-based 2222 compounds, $Bi_2Sr_2(Ln_{1-x}Ce_x)_2Cu_2O_{10+y}$, we ground a mixture of stoichiometric amounts of Bi_2O_3, $SrCO_3$, Ln_2O_3 (Ln = Sm, Eu or Gd), CeO_2 and CuO and fired it at 900 °C for 10 h; we then reground it and refired it at 990 °C for 10 h. We pressed the resulting powder into pellets and sintered it at 1,000 °C for 10 h. All firing procedures were done in air and followed by slow cooling. According to the X-ray powder diffraction patterns (see Fig. 1), the materials were nearly single phase for cerium concentrations x in the range 0.03-0.25. We found no evidence in the X-ray diffraction patterns for any superconducting T* phase[6], Bi-2201, 2212 or 2223 phases. These would complicate our interpretation of the observed superconductivity. We prepared the corresponding thallium-based compounds, $Tl_2Ba_2(Eu_{1-x}Ce_x)_2Cu_2O_{10+y}$, by thoroughly mixing stoichiometric quantities of Tl_2O_3, Eu_2O_3, CeO_2 and $BaCuO_2$ with a 10% excess of Tl_2O_3. After grinding, we pressed the mixture into a pellet, wrapped it in gold foil, fired it at 890 °C for 3 h in a sealed quartz tube containing ~1 atm of oxygen, and then slowly cooled it. We readily obtained the desired 2222 phase for compositions near $x = 0.1$, although the resultant material did contain several per cent of the 1212 phase[4,5].

We determined the crystallography and microstructure of both 2222 derivatives using X-ray diffraction and transmission electron microscopy (TEM). Tl-2222 is tetragonal (space group $P4/nmm$) with $a = 3.888(2)$ Å and $c = 17.281(7)$ Å; the unit cell is shown in Fig. 2*a*. Like the 2212 structure (Fig. 2*b*), the 2222 structure contains two pyramidal CuO_2 sheets between the BiO or TlO bilayers but, instead of a layer of Ca^{2+} ions, there is an intervening fluorite-like $(Ln_{1-x}Ce_x)_2O_2$ layer between the two CuO_2 sheets. As a result, the copper in adjacent CuO_2 sheets are displaced by $(a+b)/2$ in the tetragonal cell. Figure 3 is a high-resolution TEM image along the [100] direction of a $Tl_2Ba_2(Eu_{0.9}Ce_{0.1})_2Cu_2O_{10}$ crystal. The simulated-image inset in Fig. 3, which is based on the unit cell derived from X-ray diffraction data, is in good agreement with the actual image. By contrast to the thallium derivative, Bi-2222 is slightly orthorhombic. The unit-cell axes (Table 1) for this phase (compared to Tl-2222) must be rotated ~45° about the c axis and redefined with $a \sim b \sim \sqrt{2}a_p$ (the perovskite unit-cell lattice parameter, a_p is 3.88 Å). Electron diffraction patterns taken on and about the (001) zone axis revealed that there is a strong commensurate superlattice modulation with wavevector $[\frac{2}{9}\ 0\ \frac{1}{2}]$ in the $\sqrt{2}a_p \times \sqrt{2}a_p$ setting. Given the structural similarity of Bi-2222 and Bi-2212, we speculate that the modulation arises from the insertion of one extra oxygen for every nine bismuth atoms in the BiO bilayers. Iodometric titration measurements on Bi-2222 are consistent with this hypothesis (see below). The results of the Rietveld analysis on Bi-2222 samples with stoichiometries $Bi_2Sr_2(Ln_{1-x}Ce_x)_2Cu_2O_{10}$ ($x = 0.15$-0.25) (Ln = Sm or Gd) are listed in Table 1. Unlike 2212 and 2223, neither 2222 derivative contained extensive intergrowths or stacking defects and no twins were observed in cleaved flakes of Bi-2222. We did not perform the neutron diffraction measurement because the compounds contain strongly neutron-absorbing rare-earth elements.

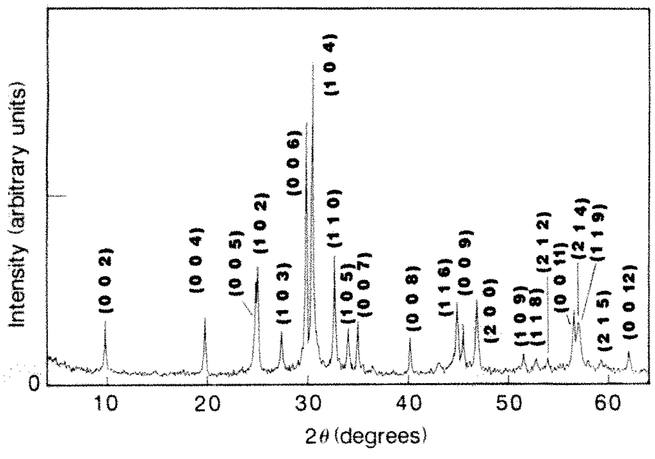

FIG. 1 Powder X-ray diffraction pattern for new Bi-2222 phase.

The 2222 structure is closely related to those of well-known bismuth- and thallium-based compounds[1-5], but has a different stacking of Cu-O sheets. In the T* phase[6] and in the recently discovered Eu-Ba-Ce-Cu-O phase[7], the fluorite-like layers are sandwiched between K_2NiF_4-type units and disordered CuO chains, respectively, rather than between BiO and TlO bilayers as in our 2222 phase. Both of these phases have $T_c \sim 25$-35 K (refs 6, 7). While preparing this work for publication, we became aware of the discovery[8] of a (non-superconducting) thallium-based compound with fluorite-like layers, but this structure has TlO monolayers rather than bilayers.

We probed the superconductivity in the Bi-2222 compounds by measuring the Meissner effect. Figure 4 shows the results measured with 10-Oe field cooling for $Bi_2Sr_2(Ln_{0.85}Ce_{0.15})_2Cu_2O_{10+y}$, (Ln = Sm, Eu and Gd). In all compounds, we observed a substantial Meissner signal with an onset T_c of ~25 K and a magnitude >10% of the ideal value, which ensures the bulk nature of the observed superconductivity. To produce the superconductivity in the Bi-2222 samples, extensive oxygen annealing was necessary. We oxygenated the samples for which the data are plotted in Fig. 4 under 80 atm of oxygen at 550-600 °C for 10 h. By iodometric titration, we determined the amount of extra oxygen y, which is postulated to reside in the BiO bilayer, to be $y \sim 0.24 \pm 0.02$. For the same oxygenation conditions, the y value was approximately constant for samples with $x = 0.15$-0.25, but decreased for compounds with less cerium. Because the valence of the cerium ion in the fluorite-like layer is very likely[9] to be 4+, the effective $[CuO]^{p+}$ charge or the concentration p of chemically doped holes per

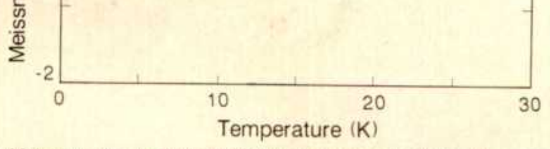

FIG. 4 Meissner signals of Bi-2222 phase compounds, $Bi_2Sr_2(Ln_{0.85}Ce_{0.15})_2Cu_2O_{10.2}$ (Ln=Sm, Eu and Gd). We plot the ratio of magnetization *M* to applied field *H*, for $H=10$ Oe. The Curie-like contribution of magnetic lanthanide ions was subtracted.

copper atom is given by the relation, $p=y-x$. The Bi-2222 samples all have positive *p* values in the range 0–0.1, indicating that the charge carriers are holes and not electrons, by contrast to cerium-doped Ln_2CuO_4 compounds[9,10]. This is also consistent with preliminary results of thermopower measurements, which show the existence of positive charge carriers. The cerium ions stabilize the fluorite-like Ln_2O_2 layer, as observed in other families of layered copper oxides[6,9], and also reduce the total number of holes introduced by the excess oxygen. In fact, highly cerium-doped compounds ($x=0.25$) showed semiconducting or insulating behaviour in the temperature dependence of their resistivity.

According to iodometric-titration analysis, the above mentioned oxygenation procedure can increase the hole concentration up to $p=0.10$ in Bi-2222, nevertheless T_c remains around 25 K for Ln = Sm, Eu or Gd. It is more difficult to characterize the stoichiometry or control the oxygen content of Tl-2222 than it is for Bi-2222, but according to our preliminary data the samples show metallic transport behaviour.

The low T_c observed in Bi-2222 is in sharp contrast to the higher T_cs observed in the 2212 compounds (80–108 K) and the 2223 compounds (110–125 K) with comparable values of *p* (≈ 0.1–0.2). We note that the 2222 and 2223 compounds have a repeat unit of nearly the same size between the BiO or TlO bilayers: the fluorite-like layer in the 2222 phase contains one O_2 sheet sandwiched by two lanthanide layers, which corresponds well to the CuO_2 sheet between the calcium layers in the 2223 phase (Fig. 2*a*, *c*). According to the empirical law for charge-carrier types[9,10], an isolated CuO_2 sheet with no apical oxygen cannot sustain holes as charge carriers but can be doped with electrons, whereas the reverse is true for the pyramidal CuO_2 sheet. Therefore, the hole-type carrier motion is probably primarily restricted to the pyramidal CuO_2 sheets in 2223. The distance $d=5.9$ Å between the hole-conducting pyramidal CuO_2 sheets in 2222 ($T_c=25$ K) is comparable to that ($d=6.4$ Å) in 2223 ($T_c=110$–125 K). Why then is T_c so low in the 2222 compound? One of the most significant differences between the 2222 compound and the 2212 or 2223 compounds may be the relative arrangement of the adjacent pyramidal sheets (Fig. 2). Another factor may be the larger in-plane Cu–O bond lengths[11] (induced by the presence of the fluorite-like layers) in the 2222 compounds, which might decrease T_c. Instead of depending simply on the number of Cu–O sheets between the BiO and TlO bilayers, it seems that T_c depends strongly on a combination of factors, including the stacking pattern of these sheets, the Cu–O bond lengths and the carrier concentration. □

Wave damping by rain

M. Tsimplis & S. A. Thorpe

Department of Oceanography, University of Southampton SO9 5NH, UK

It is common knowledge among seafarers that rain "knocks down the sea"[1,2] or that surface-wave breaking is suppressed by heavy rain. Although no quantitative data exist, several mechanisms have been proposed that might account for the attenuation of waves by rain. The most likely seems to be that raindrops produce turbulence in the water which then helps to dissipate the waves. Here we describe laboratory experiments which show that, in the absence of wind, rain preferentially damps short-wavelength gravity waves. The observed damping rates are, however, lower than earlier predictions[3,4]. The suppression of short waves has an effect on the sea surface similar to that of an oil film, leading to a reduction in the breaking of long waves. The phenomenon is important because it helps to provide insight into other aspects of wave breaking or wave suppression, and because of its bearing on the detection and estimation of rainfall at sea from ambient noise levels[5], and of the measurement of winds using radar, as scatterometer estimates of wind speed are known to be biased when it rains[6]. Wind speed is determined from an empirical relation with the observed strength of the backscattered radar signal. Although the signal may be influenced by atmospheric effects in rain, the very-small-scale roughness of the surface caused by rain drops or, as we shall show, the reduction of the 10-cm-scale waves, may also affect the signal and hence the wind-speed estimate.

Observations[7] and analytical studies[8] have shown that, in windy conditions, rain may enhance the net stress of the wind on the sea surface and, at first sight, suppression of wave breaking is therefore unexpected. The phenomenon is, however, far from simple. Rain modifies the structure of the atmospheric boundary layer[9]. The differential velocity of raindrops striking the moving sea surface induces both normal and tangential stresses on the water[3]. The net stress contributes both to waves and mean currents. The impact of raindrops produces capillary gravity ripples[10], sub-surface vortex rings[2] and vertical mixing[3,4], bubbles[11,12] and the generation of secondary drops—for example, when large bubbles burst on returning to the surface. A thin fresh-water mixing layer may build up at the sea surface[13], with density gradients restricting diffusion[14].

The full problem is very complex and we therefore conducted laboratory experiments in which only the most essential elements are retained—the rain (all of the same drop size) and the waves on fresh water—neglecting, for the present, the added complexity of wind and salinity. We used a wave tank that is 14 m long, 0.6 m wide and 0.6 m deep (Fig. 1). We produced drops of radius $R = 1.6$ mm with an array of 3,200 hyperdermic needles mounted 25 mm apart, in a triangular pattern and set in the base of waterfilled trays mounted 1.25 m above the water surface. The 'artificial rain' covered a 2-m-long section spanning the wave tank. Drops reached the water surface with a fall speed W of 4.5 m s^{-1}, about half their terminal fall speed[15], but with an intensity I of 600 mm hr^{-1}, greater than usual under natural conditions. The net flux of kinetic energy per unit area of the water from the artificial rain, $\frac{1}{2}\rho W^2 I$, where ρ is the density of water in raindrops, was comparable to that of natural rain. We produced waves of frequency $\sigma = 1.8$–4.2 Hz using a wedge at one end of the tank. These waves passed through a capacitance wire gauge, through the 'rain' section and then through a second gauge before finally being absorbed on a 'beach'. In our first, 'no-rain', experiments we used the gauge outputs averaged over 40 waves to determine a damping coefficient δ (a function of σ, or of wavenumber k) from $a_2 = a_1 \exp(-\delta d)$, where a_1, a_2 are the wave amplitudes at the first and second gauges and d is their separation. Damping is the result of viscous dissipation at the sides and bottom of the tank[16], and in the interior and at the surface of the fluid[17]. We found the second source of damping to be dominant, with a value larger than that of molecular viscosity at a clean water surface

$$\delta = 4\sigma^5 \nu / g^5 \tag{1}$$

(where g is the acceleration due to gravity), but well below that of a surface at which tangential motion is entirely suppressed (Fig. 2). (As the water surface was not 'pre-cleaned' we expected some slight contamination.) At frequencies ≤ 16 rad s^{-1} (2.5 Hz), measurements were affected by wave reflection from the beach and the presence of cross-waves. Measurements of short waves (frequencies >25 rad s^{-1} or 4 Hz) were affected by errors due to capillary effects at the wave gauges.

Our experiments with rain showed enhanced damping. To derive the attenuation rate Δ for surface waves in the rain (Fig. 3*a*), we used the attenuation rate δ to account for wave damping in the area between the gauges but outside the 2-m rain zone, and also corrected for side and bottom damping in the rain zone. We have estimated the damping owing to (1) the pressure of the rain on the advancing waves, (2) the tangential stress on the moving water surface that is due to the relative speeds of rain drops entering the water, and (3) the momentum loss of the waves through the interaction with capillary gravity waves produced by raindrops is not appreciable. This net contribution,

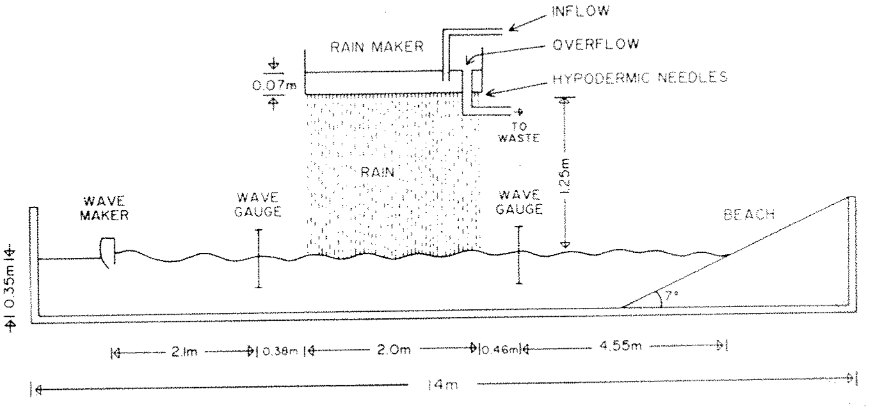

FIG. 1 The experimental apparatus. Artificial rain is produced from an array of hypodermic needles set in the bottom of a tray and falls onto waves produced by a wavemaker. The wave gauges are 0.315-mm-diameter capacitance wire probes located on the centre line of the tank.

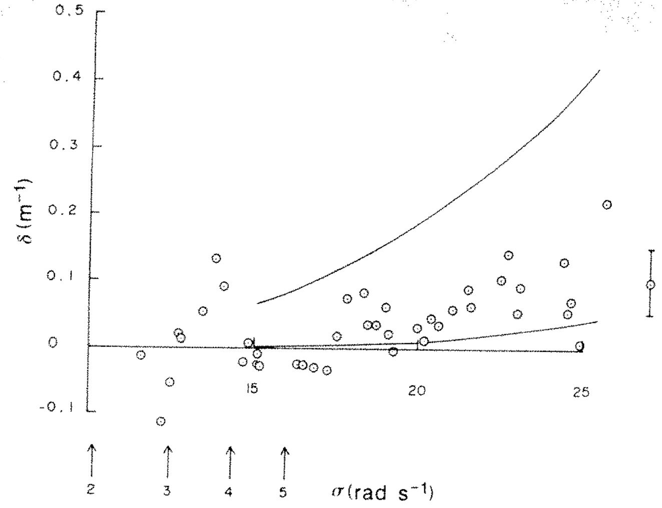

FIG. 2 The damping rate δ as a function of frequency σ of waves in the absence of rain. We have corrected the data for the effects of side walls and tank bottom. The vertical bar indicates the possible uncertainty associated with each estimate. The arrows marked 2–5 indicate the frequencies at which cross-waves may occur; the number is the mode number. The lower curve is the predicted curve with a free upper surface and $\nu = 1.1\times10^{-6}\ \mathrm{m^2\ s^{-1}}$. The upper curve is that predicted for a contaminated water surface with no tangential motion possible.

assuming the molecular viscosity and no turbulent motion, is $\leq$10% of the observed damping. By analogy with equation (1) the damping by vertical mixing may be represented

$$\Delta = 4\sigma^5 \nu_e / g^3 \qquad (2)$$

where ν_e is an effective viscosity. Figure 3*b* shows values of ν_e derived from equation (2), which have a mean value of $2.84\times10^{-5}\ \mathrm{m^2\ s^{-1}}$ for σ in the range 16.0–25.2 rad s⁻¹. The curve in Fig. 3*a* shows Δ as a function of σ for this mean value. We found no significant dependence of ν_e on wave steepness ($0.05 < a_1 k < 0.3$).

Yakimov[10] has suggested $\nu_e = bLI[1-\exp(-2\sigma^2 L/g)]$, where b is estimated to be ~15 and represents the mass carried down in the water by each raindrop divided by the mass of the drop, and L is the depth to which mixing extends, assumed[10] to be ~5 cm. Agreement with the observed ν_e requires $L = 1.2$ cm, which is less than the observed mixing-layer thickness; the formula seems to overestimate ν_e. ($L = \nu_e/I$ corresponds to the boundary-layer thickness predicted for flow at rate I through a porous wall into a fluid of viscosity ν_e. Using our experimental parameters, $L = 17$ cm, which is not inconsistent with depths observed when artificial rain was dyed.) Manton's[3] proposal, $\nu_e = RI^{1/6}W^{5/6}$, gives ν_e in terms of known parameters but it overestimates $\nu_e(1.31\times10^{-3}\ \mathrm{m^2\ s^{-1}})$.

We can judge the possible importance of rain damping in modifying the wave field by comparing the observed Δ with the growth rate of waves that is due to wind[18], $\beta = 0.04k\ (u_*/c)^2$, where u_* is the friction velocity, which is ~0.04 times the wind speed 10 m above the water surface, W_{10}, and $c = \sigma/k$ is the phase speed. Assuming the gravity-wave dispersion relation, $\sigma^2 = gk$, β and Δ (given by equation (2)) are equal when $\sigma\nu_e = 1.6\times10^{-5}W_{10}^2$. In a wind of 6 m s⁻¹, damping at the rate observed in the experiments would exceed the growth induced by the wind for waves of frequency >20 rad s⁻¹ (wavelength $\leq$0.16 m).

A further contribution to short-wave dissipation in windy conditions is due to the enhancement of wind stress by rain[7,8] and a consequently increased surface wind drift current. The rain-induced stress $\tau_r \simeq 0.85\rho I W_{10}$ (ref. 8), together with the wind stress τ lead to a surface drift q proportional to $[(\tau+\tau_r)/\rho]^{1/2}$, which increases with rain intensity. This then leads to a reduction in the amplitude, $a = (c^2/2g)(1-q/c)^2$, at which short gravity waves break[19]. This small-scale breaking represents an increased rate of energy loss from the short waves, and to waves of smaller mean amplitude.

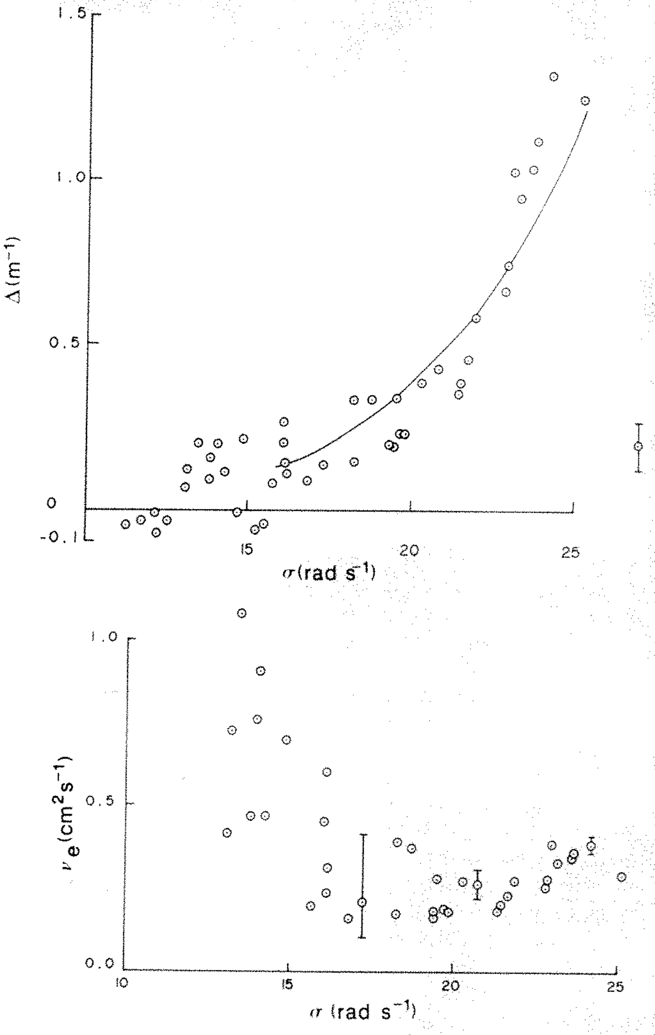

FIG. 3 *a*, The damping rate Δ as a function of frequency σ of waves in rain, with side-wall and tank-bottom effects removed. The vertical bar indicates the possible uncertainty associated with each estimate, and the curve is that given by equation (2) with the average value of ν_e. *b*, The effective viscosity ν_e as a function of wave frequency σ, using only values of $\Delta > 0$ in *a*. The vertical bars indicate the possible uncertainty associated with each estimate. Points for $\sigma < 16$ rad s⁻¹ are seriously affected by cross-waves and edge-waves at the beach and should be discounted. There seems to be no significant trend in ν_e for σ in the range 16–25.2 rad s⁻¹.

Short waves with $k > g/(25u_*^2)$, which include those severely damped by rain, constitute a major component of the roughness of the surface, which is important in the transfer of momentum from the wind to the larger waves[20]. Although raindrops, and splashes, roughen the sea surface at the scales of capillary gravity waves, the attenuation of the short gravity waves caused either by the enhanced turbulence observed in experiments or by their dissipation through small-scale breaking as indicated above, will reduce the surface roughness and hence the momentum transfer to the longer waves, and so diminish the frequency of the more violent form of breaking associated with the longer waves, which are a hazard to mariners. By reducing the short waves, rain calms the sea in a way similar to oil[21]. In the absence of wind, as in the experiments, heavy rain tends rapidly to attenuate short waves typical of lakes or fjords, and contributes to the glassy appearance of their surfaces commonly observed once the rain has stopped. Further experiments to determine the functional relation of I and W are necessary, as is a comprehensive study of rain and wave interactions in windy conditions[6]. □

NITROUS oxide plays an important part in atmospheric chemistry; it is a 'greenhouse' gas and has the potential to destroy ozone. Concentrations of N_2O in surface waters of the oceans are generally close to equilibrium with the atmosphere, but sub-surface sea water is supersaturated with N_2O[1–5]. The oceans are now regarded as a source[4] for atmospheric N_2O by production through the oxidation of ammonium ('nitrification')[1,3], except in extremely oxygen-deficient waters[6]. Nevertheless, the possibility that N_2O might be produced through the reduction of nitrate ('denitrification') cannot be ruled out[5,7]. The distribution of ^{15}N in atmospheric and oceanic N_2O can be used to investigate the behaviour of N_2O in the oceans[8,9]. Here we report simultaneous measurements of the nitrification rates and nitrogen isotope data for N_2O and NO_3^- produced in the western North Pacific Ocean. The amount of N_2O produced by nitrification is much lower than that expected from the production of NO_3^-. The N_2O in the oxygen-deficient layer is more enriched in ^{15}N than NO_3^-. These results imply that the contribution of nitrification to the production of N_2O is lower than previously thought and that denitrification is primarily responsible for the production of N_2O.

During a cruise (August–September 1983) of the RV *Hakuho Maru* in the western North Pacific Ocean we collected seawater samples at depths ranging from the surface to 4,800 m at Station C (45° 09′ N, 160° 18′ E) and from the surface to 4,000 m at Station E (28° 06′ N, 152° 56′ E). Figures 1 and 2 show the vertical profiles of the N_2O concentration, $\delta^{15}N$ values and the potential production rate of N_2O and NO_3^- by nitrification and the dissolved oxygen at Stations C and E, respectively. The dissolved N_2O concentrations in surface water (9.0 nM at Station C and 5.6 nM at Station E) agree well with the equilibrium values estimated using solubility data of N_2O (ref. 13). The maximum concentrations of N_2O occur at a depth of 700 m at Station C and at 1,300 m at Station E, where the dissolved oxygen is a minimum. There is a strong correlation between the N_2O and NO_3^- concentrations and a negative correlation between the N_2O and O_2 concentrations at both stations, as shown in Fig. 3. These correlations are similar to those reported for other areas of the oceans[1–5,7] except for the deep-water column at Station E where a water mass enriched in NO_3^- and depleted in N_2O (ref. 4) is mixed in. The lines in Fig. 3 'turn over' because of the depth dependence—N_2O is generally depleted in bottom waters.

The $\delta^{15}N$ value of the dissolved N_2O in surface water is

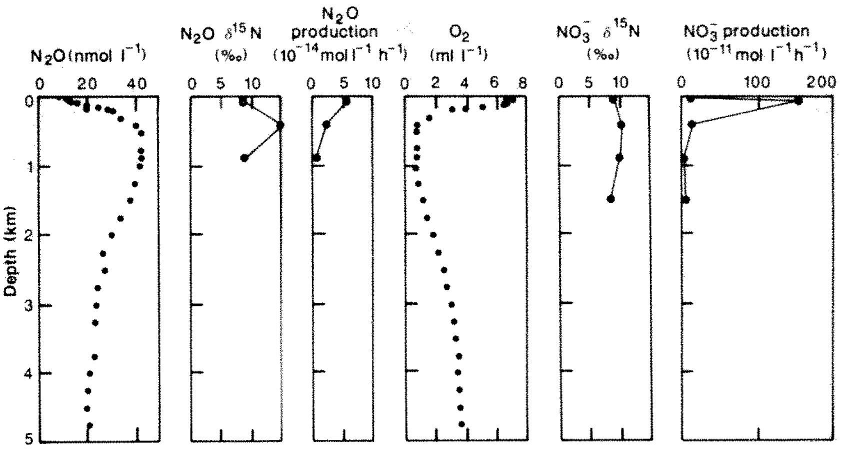

FIG. 1 The vertical profiles at Station C of (from left to right) N_2O, $\delta^{15}N$ of N_2O, the potential production rate of N_2O by nitrification, dissolved O_2, $\delta^{15}N$ of NO_3^- and the potential production rate of NO_3^- by nitrification.

METHODS. We determined the N_2O concentration of the water samples, which had been stored in 100-ml air-tight glass containers, using the method given in ref. 10. We determined using a method we have described elsewhere[9], the ^{15}N content ($\delta^{15}N = ((^{15}N/^{14}N)_{sample}/(^{15}N/^{14}N)_{standard}) - 1$, the standard is N_2 purified from the atmosphere) of N_2O in 100-l samples collected at several depths at the two stations; to determine the $\delta^{15}N$ of NO_3^- we used the method in ref. 11 (5-l samples). We estimated (on board) the production rates of N_2O and NO_3^- by nitrification using ^{15}N-tagged NH_4^+. We added 5 μmol of NH_4^+ (99.8 atom% ^{15}N) to a 5-l water sample contained in an air-tight vessel. After incubating the sample at approximately the *in situ* temperature for 48 h (in the dark), we added 5 ml of 0.1M $HgCl_2$ to stop the bacterial reactions. We used the same method to remove the N_2O as we used to remove N_2O having a natural abundance of ^{15}N. We determined the $\delta^{15}N$ of the 50–200 nmol N_2O so collected by adding a known amount (~1 μmol) of N_2O having $\delta^{15}N = -2.9$‰. We measured the $\delta^{15}N$ of NO_3^- using the same method as we used for NO_3^- having a natural ^{15}N abundance. At the start of the incubation the NH_4^+ is ~1 μM, about ten times larger than the saturation concentration for nitrification[12]. The rates that we calculate correspond to the potential production rates of N_2O and NO_3^-. The precision of the measurements are ±2%, ±0.2‰ and ±3% (1σ) for N_2O, $\delta^{15}N$ and production rates, respectively.

concentration would be proportional to the apparent oxygen utilization.

The nitrous oxide at the concentration maxima of both stations is found to be more enriched in ^{15}N than that in equilibrium with atmospheric N_2O and NO_3^-. The enrichment in ^{15}N of N_2O that we found has been observed in the oxygen-minimum layer of the eastern tropical Pacific Ocean, where denitrification prevails[9]. The δ^{15}N values of N_2O correlate with those of NO_3^- (Fig. 4). This indicates that most of the N_2O is involved in the NO_3^- reduction system. Nitrous oxide is consumed as well as produced in the NO_3^- reduction system. As a result, the δ^{15}N of N_2O is determined by the fractionation factors during both production and consumption. We have observed a kinetic nitrogen isotope fractionation factor during the reduction of N_2O by denitrifying bacteria of up to 1.028 in terms of the rate-constant ratio of the isotope species, $k(^{14}\text{N})/k(^{15}\text{N})$ (ref. 24). If the ^{15}N enrichment of substrates is greater during consumption than during production, the enrichment in ^{15}N of N_2O relative to NO_3^- should result. The concentration and the δ^{15}N value of N_2O are consequently determined by those of NO_3^-. □

Evidence for a change in the periodicity of tropical climate cycles at 2.4 Myr from whole-core magnetic susceptibility measurements

Jan Bloemendal* & Peter deMenocal†

Palisades, New York 10964, USA

THE Earth's orbit about the Sun is influenced by gravitational interactions with the Moon and other planets. The resulting orbital perturbations give rise to cyclical variations in orbital eccentricity, obliquity and precession with periods of 100, 41, 19 and 23 kyr, respectively[1]. These variations are climatically important because they affect the seasonal and latitudinal distribution of solar radiation. Magnetic-susceptibility measurements in deep-sea sediment cores can be used as a sensitive indicator of temporal variations in the concentration of terrigenous material supplied to the sea bed. Here we use this approach to study the evolution of cycles of terrigenous sedimentation at Ocean Drilling Program sites in the Arabian Sea and the eastern tropical Atlantic. We show, from spectral analyses of the two susceptibility time series spanning the past 3.2–3.5 Myr, that the records are driven strongly by orbital forcing. Before 2.4 Myr before present (BP), both records are strongly influenced by the 23- and 19-kyr periodicities; but after 2.4 Myr, they are both significantly influenced by the 41-kyr periodicity. This shift coincides with the beginning of major Northern Hemisphere glaciation, which indicates, for the Indian Ocean site, that the supply of terrigenous sediment (carried by monsoonal winds) has responded to the rapid increase in ice cover at this time. We cannot, however, exclude possible effects of changes in bottom-water circulation on the susceptibility record of the Atlantic site.

Statistical analyses of the foraminiferal δ^{18}O record from deep-sea cores (largely a measure of glacial ice volume[2]) demonstrate that the growth and decay of ice sheets have been strongly modulated by orbital insolation variations[3]. Similarly, other major components of climate[4–8] vary predominantly at orbital periodicities. However, measurement of conventional palaeoclimatic indicators (for example, oxygen and carbon isotopes, carbonate, opal and terrigenous fraction content) in deep-sea sediments is time consuming; consequently, palaeoclimate indicators that can be measured more easily are needed.

Magnetic susceptibility is the ratio of induced magnetization to an applied weak magnetic field and is proportional to magnetic mineral concentration, which is typically a trace component of the terrigenous fraction[9–11]. Susceptibility measurements are extremely rapid, and whole cores can be measured continuously using a pass-through loop sensor. Provided that susceptibility is correlated to terrigenous-fraction variations, these measurements can offer a highly efficient means of acquiring high-resolution palaeoclimate data.

The major aims of Ocean Drilling Program Legs 108 (eastern tropical Atlantic) and 117 (Arabian Sea) were to study the late Neogene evolution of northwest African climates and the Asian

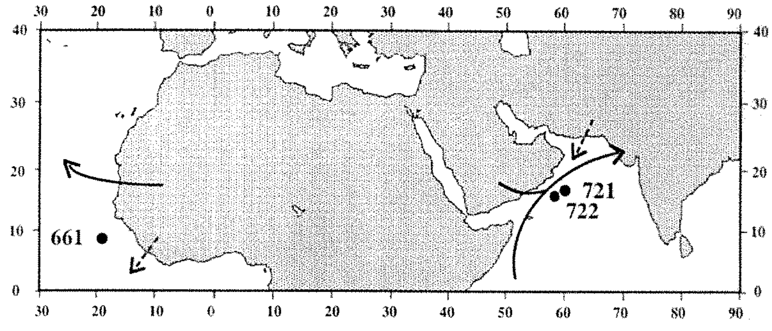

FIG. 1 Locations of ODP Leg 108 Site 661 and ODP Leg 117 Site 721. Solid arrows depict the modern summer monsoonal dust trajectories, dashed arrows depict the winter trajectories[13,17].

monsoon. In the case of the Asian monsoon, summer heating result in the development of an intense low-pressure cell over the Tibetan Plateau; consequently, in the northwest Arabian Sea, strong moisture-laden southwesterly winds transport abundant aeolian detritus[12] to the Arabian Sea region and bring monsoon rains to southern Asia[13]. The northwest African monsoon is driven by the same mechanism: summer heating of North Africa drives the cyclonic inflow of moisture-laden air into the Sahel and south Sahara.

Both general circulation model (GCM) experiments[14] and analyses of aeolian and biogenic components in deep-sea cores[5,6,14] have demonstrated that seasonal insolation variations resulting from orbital precession have modulated the intensity of the Asian and African monsoons. Precession affects low-latitude summer insolation at periodicities of 23 and 19 kyr (ref. 1); maximum summer insolation is achieved when the summer solstice coincides with perihelion, and palaeoclimate data have demonstrated that the African and Asian monsoon systems were intensified at these times[5,6].

Site 721 (Fig. 1) is located in the Arabian Sea in water of depth 2,028 m near the crest of the Owen Ridge, which rises 2,000 m above the surrounding bathymetry. Satellite imagery[15] and sediment-core studies[15,16] demonstrate that terrigenous sedimentation in the Arabian Sea is dominantly aeolian. Site 661 (Fig. 1) is located in 4,013-m water depth on the eastern slope of the Kane Gap in the eastern tropical Atlantic. Today the area receives a substantial supply of aeolian dust from the African winter dust plume[17]. The fact that it is not situated on a bathymetric high suggests that carbonate dissolution and advective sediment supply may have been significant sedimentary processes.

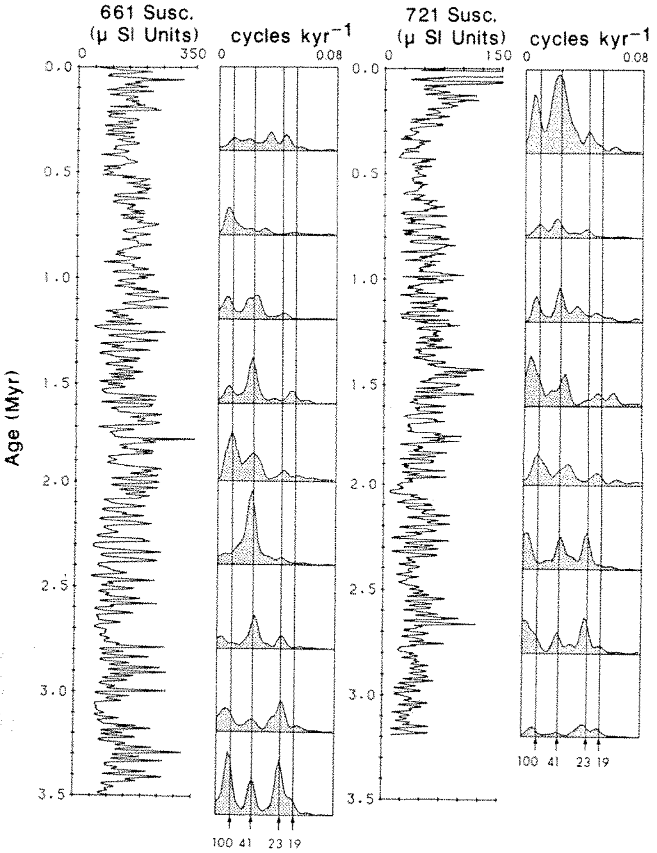

FIG. 2 Susceptibility (Susc.) time series for Site 661 (eastern equatorial Atlantic) and Site 721 (Arabian Sea). The time series were divided into 0.4-Myr intervals and spectral analysis (Sande-Tukey radix-two fast fourier transform with modified Daniell smoothing[21]) was performed on each of these intervals. The vertical lines represent (from left to right) the 100-kyr, 41-kyr, 23-kyr and 19-kyr orbital periodicities. Note the increase in power at the 41-kyr periodicity at both sites after ~2.4 Myr.

At both sites whole-core volume susceptibility was measured at 3-5 cm intervals during the occupancy of the site. Between-hole correlations[18] using the susceptibility data were used to construct complete composite sequences. Age models were constructed using bio- and magnetostratigraphic data[19,20]. At Site 721 oxygen isotope data (W. L. Prell, unpublished data) were used to construct age-depth relations for the interval 0–1 Myr. The age models included as many data as possible within a series of straight-line segments. The record for Site 661 extends to 3.5 Myr and that for Site 721 extends to 3.2 Myr. Each time series was divided into 0.4-Myr intervals and spectral analysis[21] was performed on each interval. The resulting periodograms clearly demonstrated that variance was concentrated at orbital periodicities; minor adjustments were then made to some data (within their uncertainty limits) to improve the alignment of the peaks with the orbital periodicities.

Figure 2 shows the susceptibility time series and periodograms. The periodograms indicate a shift in spectral character at ~2.4 Myr. Before 2.4 Myr (2.4–3.5 Myr at Site 661; 2.4–3.2 Myr at Site 721), the data vary predominantly at the 23- and 19-kyr precessional periodicities. In each periodogram, the variance associated with this precession component significantly exceeds that associated with obliquity. After 2.4 Myr there is an increase in variance at the 41-kyr periodicity at both sites, and a corresponding reduction in variance at the 23- and 19-kyr periodicities. At Site 721, increased variance at the 41-kyr periodicity persists over the entire 0–2.4-Myr interval. At Site 661, the periodograms for the interval 0.0–0.8 Myr do not show variance at orbital frequencies; this may reflect an inadequate age model for this interval.

To examine the coherency between the susceptibility records and the orbitally driven insolation variations, the time series were filtered using a bandpass filter centred at 22 kyr, corresponding to orbital precession. The extracted component was then correlated ('tuned') to the calculated precession curve[1] using an inverse-correlation method[3,22]. Although coherency between the filtered susceptibility data and precession was not evident for Site 661, the filtered susceptibility data at Site 721

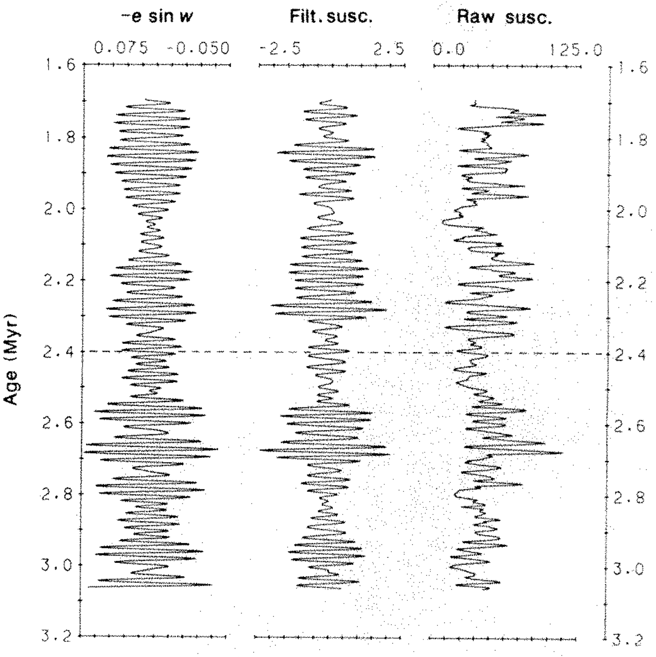

FIG. 3 Calculated orbital precession index (−*e* sin *w*), the 22-kyr filter of the susceptibility record and the raw susceptibility record for the 3.2–1.6-Myr interval at Site 721. The filtered data exhibited the modulated character of the precession record, and were therefore correlated ('tuned')[3] to the precession curve using an inverse-correlation method[22]. The 'tuned' age-depth data are within the uncertainties of the original age-depth model[23]. The coherency over the entire interval is 0.86; coherency from 3.2–2.4 Myr is 0.89.

exhibits the modulated character of the precessional curve (Fig. 3). Coherency over the 3.2-1.6-Myr interval is 0.84 and is even higher (0.86) from 3.2-2.4 Myr (ref. 23). Although the tuning procedure maximizes the correlation between the two signals, the coherency of the 400- and 100-kyr modulation envelopes is a real component of the susceptibility data. These data document the oldest and longest sequence demonstrating both power and coherency at the precessional band. We consider that these results demonstrate the strong orbital control of the susceptibility records at both sites, together with a shift from strong precessional forcing before, and strong obliquity forcing after, ~2.4 Myr. This raises the questions of what aspects of the relevant climate systems do the susceptibility records reflect; and what is the significance of the periodicity shift at 2.4 Myr?

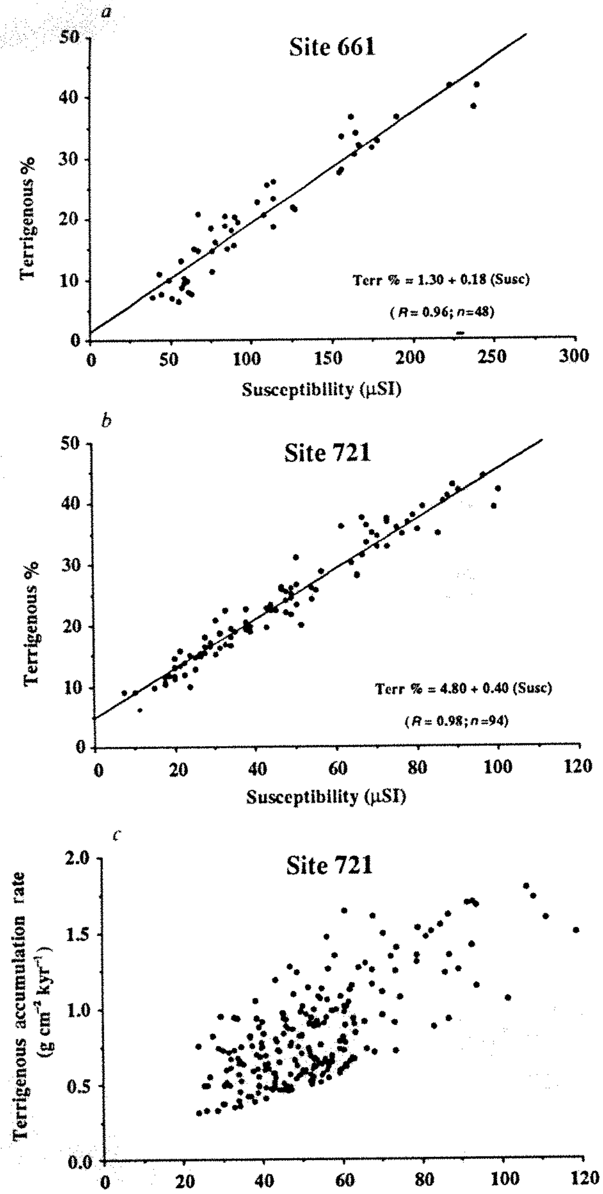

FIG. 4 *a, b,* Correlation between susceptibility and per cent terrigenous sediment for the Site 661 and Site 721 sediments. The terrigenous per cent values were calculated after sequentially removing calcium carbonate, opal and organic carbon components[23,24]. *c,* Correlation between susceptibility and terrigenous accumulation rate for the 2.5-2.7-Myr interval of Site 721. Because the susceptibility is highly coherent with orbital precession over this interval (see Fig. 3), detailed accumulation-rate data were calculated by phase-locking ('tuning') the raw susceptibility record to precession. The resulting accumulation-rate time series was combined with the relation shown in *b* to calculate the separate biogenic and terrigenous accumulation-rate data. The strong positive correlation indicates that susceptibility at Site 721 is reflecting variations in terrigenous accumulation, not biogenic dilution. The susceptibility-biogenic accumulation-rate plot, for which the correlation is poor, is not shown.

Terrigenous extraction procedures[24] were conducted on 94 samples from Site 721 (ref. 23) and 64 samples from Site 661. These data (Fig. 4*a, b*) show that susceptibility is an accurate proxy indicator of terrigenous content at both sites. Using the 'tuned' Site 721 susceptibility record to generate detailed age-depth relations for the 2.7-2.5 Myr interval, we converted the terrigenous concentrations to accumulation rates[23]. Figure 4*c* shows the strong positive correlation between susceptibility and terrigenous accumulation rate, indicating that the susceptibility variations are reflecting variations in terrigenous supply rather than biogenic dilution; by contrast, the correlation between susceptibility and biogenic accumulation rate was poor. A study of late Pleistocene terrigenous accumulation on the Owen Ridge[16] supports this conclusion.

The strong relationship between susceptibility and the concentration and accumulation rate of the terrigenous fraction, and the occurrence within this fraction of minerals indicative of an aeolian source[23], leads us to conclude that the Site 721 susceptibility record is a direct expression of variations in the wind transport of terrigenous material by the Asian monsoon. The interpretation of the Site 661 susceptibility record as a direct indicator of variations in terrigenous deposition is less certain. Fluctuations of deep water from Northern and Southern Hemisphere sources across the site, possibly at orbital periodicities, could have influenced its susceptibility record through variable calcite dissolution.

The predominance of 23- and 19-kyr variance in the susceptibility records before 2.4 Myr indicates that terrigenous deposition from the Asian, and possibly the African, summer monsoons was largely modulated by summer-season insolation variations due to precession. Atmospheric GCM experiments have demonstrated that monsoonal circulation is extremely responsive to precessional variations in local summer insolation, and that the response is approximately linear[14]. The marked increase in variance at the 41-kyr periodicity at ~2.4 Myr coincides with the initiation of major Northern Hemisphere glaciation[25], and GCM results and geological evidence indicate that this may reflect ice-sheet effects on the monsoon climate or the dust source regions. The increase in power at the 41-kyr periodicity is particularly significant because the late Pliocene marine $\delta^{18}O$ record varies almost purely at this periodicity[26]. GCM experiments have not unambiguously identified any direct effects of the large high-latitude Laurentide and Fennoscandian ice sheets on low-latitude hydrology[27], although there is geological evidence[10,28-30] indicating that African and Asian source areas may have experienced aridification during the last glacial maximum. Hence, the increase in 41-kyr power after 2.4 Myr may be linked to changes in the monsoon intensity or source-area climate due to the coeval expansion of the Eurasian or North American ice sheets, or both, which varied predominantly at this periodicity.

Our results clearly demonstrate the value of whole-core susceptibility logging for identifying potentially important time intervals deserving further investigation. Parallel mineralogical and grain-size studies will help to evaluate more fully the significance of susceptibility as an indicator of source-area climate and terrigenous deposition at both sites. More importantly, the integration of these data with on-going isotope and biotic assemblage studies will lead to a better understanding of the climatic origin of the 2.4-Myr shift and its relevance to other components of climate. □

Thermal entrainment by deflected mantle plumes

HOTSPOTS are thought to result from deep mantle plumes, perhaps representing an ancient geochemical source isolated from the uppermost mantle. As they rise through the mantle, thermal plumes entrain surrounding material by thermal conduction, and small plumes or narrow plume conduits may consist of only a small fraction of original source material. Here we present new experimental results which show this effect dramatically for plume conduits that are deflected horizontally by shear flow in the mantle beneath lithospheric plates. Thermally entrained material can become concentrated at the centre of a plume (or surface hotspot trace) with original source material in the periphery. Also, the diapiric instability observed in chemical plume conduits is suppressed by thermal entrainment. Varying degrees of geochemical enrichment observed at hotspots such as the Galapagos Islands may result from thermal entrainment, implying that mantle plumes are driven by thermal (rather than compositional) buoyancy.

If volcanic hotspots such as Hawaii are caused by mantle plumes[1,2], then the nature of these buoyant plumes is constrained by some striking (although not necessarily consistent) features of hotspots. Hotspot plumes must (1) represent a deep mantle source that is relatively decoupled from lithospheric plate motions, (2) transport material that is geochemically enriched relative to the depleted upper mantle, and (3) represent a horizontal scale length (~10–100 km) of convection that is much smaller than that associated with plate motions.

Although it is not clear from observations whether mantle plumes are driven primarily by thermal or chemical buoyancy, a thermal origin at the core-mantle boundary is commonly assumed. Broad-scale, two-dimensional (sheetlike) thermal plumes have been modelled in many theoretical and experimental convection studies (refs 3-5, for example) in which lower-boundary-layer instabilities develop in response to basal heating. Experimental studies of narrow isolated plume conduits[6-10] have used chemically buoyant (non diffusive) plume material. Plume conduits exhibit a fascinating variety of behaviour including solitary conduit waves[10] and diapiric instability in horizontally deflected conduits[7,8]. Thermally buoyant conduits have not been studied experimentally, however, and thermal diffusion may be expected to dominate the dynamics of very narrow plumes. (Diffusion effects are not expected to be important in compositionally buoyant mantle plumes, because chemical diffusion rates in the mantle are generally thought to be much smaller than thermal diffusion rates.) Here we present results from preliminary experiments that demonstrate the important effects of thermal entrainment for plumes deflected horizontally by mantle shear flow beneath the lithospheric plates. These results are particularly applicable to the mixing of enriched and depleted mantle reservoirs by thermal plumes.

The thermal entrainment of surrounding material by rising hot diapirs has been demonstrated by Griffiths[11,12]. Figure 1 illustrates this process in which a boundary layer of heated surrounding material becomes entrained, because of its own thermal buoyancy, into the rising diapir. As the diapir rises, a torus or smoke ring of original source material forms, with entrained material forming the central core of the diapir for initial diapir Rayleigh numbers larger than about 12 (ref. 11). We show that this process also occurs in a horizontally deflected thermal plume as the plume conduit rises through the cold surrounding material. This can be envisioned by imagining that Fig. 1 represents not a cross-section of a spherical diapir, but instead a view along the axis of a cylindrical conduit that is rising through a fluid (see refs 13, 14). The superposition of fluid flow through the conduit and the bifurcated flow pattern shown in Fig. 1 will give rise to paired, helical particle paths as material ascends through the plume conduit, with thermal entrainment of heated surrounding material into the centre of the plume.

We observed this phenomenon using a simple experimental apparatus described in detail elsewhere[13]. A cylindrical Plexiglas tank (60 cm in diameter and 10 cm high) is filled with glycerol and fitted with a lid which is rotated slowly by an electrical motor, creating a simple (circular) shear flow in the tank beneath the lid or plate. The plume is fed gravitationally through a

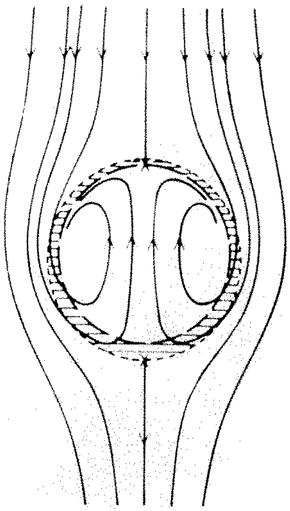

FIG. 1 Paths of fluid particles outside a hot, rising diapir[11]. Those particles that approach close to the diapir are heated by diffusion in the thin thermal boundary layer (hatched area), become buoyant, and are incorporated into the enlarging spherical vortex. In other words, they become entrained. Alternatively, this illustration can be taken as the view along the axis of a cylindrical plume conduit as in the experiments presented here.

control valve from an elevated reservoir of glycerol containing a small amount of red dye. The plume source is a small hole (0.2-cm diameter) in the base of the tank, 16 cm from the lid rotation axis. The red glycerol is heated before it enters the tank by heating tape wrapped around the copper inlet pipe. The temperature of the thermally buoyant plume material is monitored by a small thermocouple just below the inlet hole.

The photographs of Fig. 2*a*, *b* show side and top views of a horizontally deflected plume that exhibits strong thermal entrainment. The red dye (dark material) represents the original plume material injected at the base of the tank, and it forms two stripes along the outside of the plume as seen in top view. The central core of the plume consists of entrained material. The plume remains largely a circular cylindrical conduit, expanding as it rises in the tank. The relevant experimental parameters are: tank-fluid kinematic viscosity $\nu_{\mathrm{t}} = 1.5\ \mathrm{cm}^2\ \mathrm{s}^{-1}$, upper-plate velocity above the plume source $u_0 = 0.23\ \mathrm{cm\ s}^{-1}$, temperature contrast between plume source and tank fluid $\Delta T = 50\ ^{\circ}\mathrm{C}$, density contrast $\Delta\rho = 0.018\ \mathrm{g\ cm}^{-3}$. (The glycerol in this experiment absorbed some water from the air so that its viscosity was about a factor of four less than that of pure glycerol.) In the case shown, the Prandtl number is sufficiently large ($\mathrm{Pr} = 320$) and the Reynolds number (for the rise of the conduit through the tank fluid) sufficiently small ($\mathrm{Re} = 0.01$) to assure dynamical similarity to creeping flow in the mantle. The initial plume diameter is 0.3 cm and it expanded to >1.0 cm just beneath the tank lid. (We note that thermal expansion of plumes occurs whether or not there is significant horizontal deflection[15].) This represents about a factor of ten increase in plume cross-sectional area, giving an order of magnitude decrease in average temperature contrast across the plume. The half-angle expansion ratio of the conduit[11] is approximately constant at $\varepsilon = 0.049$. (ε is one-half the increase in plume diameter per unit plume-rise distance.) The original plume material accounts for only about one-tenth of the thermally expanded plume volume near the tank lid.

We can scale this experiment to plumes in the Earth's mantle by defining a conduit Rayleigh number $\mathrm{Ra} = g\Delta\rho V/\kappa\nu_{\mathrm{t}}$ where g is the gravitational acceleration and κ is the thermal diffusivity of the tank fluid. The Rayleigh number is simply a dimensionless thermal buoyancy, and it is not intended to represent the vigour of mantle convection. V is defined[13] as an effective 'conduit element' volume based on the initial conduit diameter d so that $V = 2.9\pi d^3/8$. (The factor $2.9\pi/8$ is somewhat arbitrary[13] and of no consequence with respect to the following scaling arguments.) Thus, the conduit Rayleigh number for the plume of Fig. 2*a*, *b* is $\mathrm{Ra} = 24$. This can be scaled to the mantle as follows: for a plume of reasonable density contrast $0.02\ \mathrm{g\ cm}^{-3}$ ($\Delta T \approx 200\ ^{\circ}\mathrm{C}$), diameter 50 km and thermal diffusivity $\kappa = 0.01\ \mathrm{cm}^2\ \mathrm{s}^{-1}$, and for a mantle viscosity of 10^{22} P, we obtain a similar Rayleigh number $\mathrm{Ra} = 29$. The plume-conduit Rayleigh number increases with the cube of the plume diameter and decreases with the viscosity of the surrounding fluid, and neither of these parameters is well constrained for mantle plumes. The experimental results shown are applicable, for example, for mantle-plume diameters of ~5–80 km with background mantle viscosities of $\sim 10^{19}$–10^{23} P, respectively. Clearly, the range of conduit Rayleigh numbers in our experiments may apply to real mantle plumes.

Another important parameter is the upper-plate velocity, which is $u_0 = 0.23\ \mathrm{cm\ s}^{-1}$ here. This can be scaled to lithospheric plate or mantle shear-flow velocity using the Peclet number (dimensionless velocity). The Peclet number is defined as $\mathrm{Pe} = u_0 L/\kappa$, where the appropriate scale length is the tank fluid depth $L = 10$ cm. For the experiments shown, $\mathrm{Pe} = 290$. Scaling to the Earth's mantle depth $L_{\mathrm{m}} = 3{,}000$ km and using $\kappa = 0.01\ \mathrm{cm}^2\ \mathrm{s}^{-1}$, we obtain the characteristic mantle shear velocity $u_{\mathrm{m}} = 0.32\ \mathrm{cm\ yr}^{-1}$. This is appropriate either for a very slow litho-

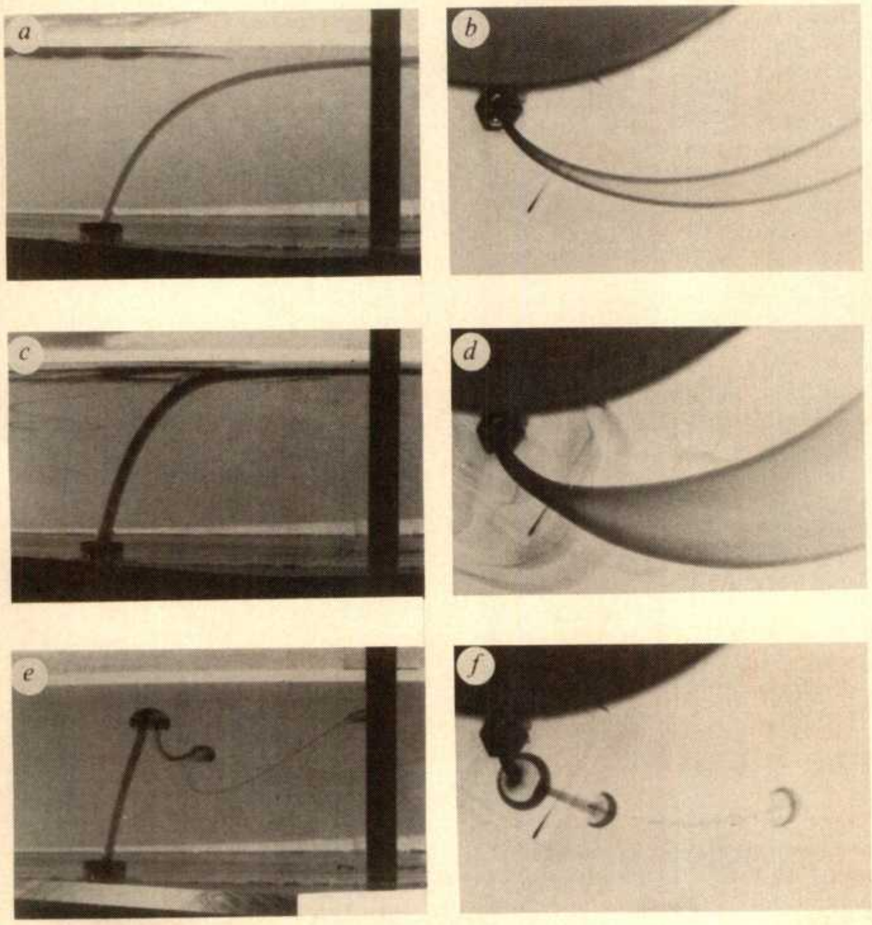

FIG. 2 Side (*a*, *c*, *e*) and top (*b*, *d*, *f*) views of the plume experiments. In *a*, *c* and *e* the dark vertical bar on the right-hand side is the lid rotation axis. The 1-cm-thick lid is the light horizontal band just above the point where the red (dark), thermal plume becomes horizontal. In *b*, *d* and *f* the drive wheel appears dark and unfocused in the upper left-hand corner. The lid rotation is counter-clockwise along the curvature of the dark plume trace. The faint grey cloud above the plume source in *d* is diffused plume material from previous experiments that has been advected around the cylindrical tank.

spheric plate or as a characteristic velocity in the Earth's deep mantle. (The relatively low-viscosity upper mantle, or asthenosphere, beneath the plates indicates deep-mantle flow velocities about an order of magnitude less than typical plate velocities[16].) Larger upper plate or shear-flow velocities, with other parameters constant, will result in more horizontal deflection[13] and even stronger thermal entrainment effects, especially for higher Rayleigh numbers.

Based on experiments with hot rising diapirs[11], we expect significant thermal entrainment for Rayleigh numbers as high as ~10,000. Figure 2*c*, *d* shows a larger plume (higher plume feed rate) under experimental conditions that are otherwise the same as for Fig. 2*a*, *b*. The initial plume diameter is 0.6 cm, yielding a higher conduit Rayleigh number of 192. The measured expansion ratio is $\varepsilon = 0.027$, which is smaller than for the previous experiment ($\mathrm{Ra} = 24$; $\varepsilon = 0.049$). This is expected, because a higher Rayleigh number implies a smaller thermal boundary-layer thickness relative to the conduit diameter. The two experiments here indicate a somewhat smaller decrease in ε with increasing Rayleigh number than for diapirs[11]. For the higher-Rayleigh-number experiment in Fig. 2*c*, *d* the original plume material constitutes only about 35% of the volume of the plume as it encounters the tank lid.

Returning to Fig. 2*a*, we note that in this experiment and for other thermal-plume conduits deflected to almost horizontal orientations (data not shown), we never observed any diapiric-conduit instability. Apparently, plumes of modest Rayleigh number are stabilized by thermal entrainment of surrounding material. This is an important observation, because diapiric instability in deflected plume conduits (observed in laboratory models of chemical plumes) has been suggested as the cause for individual volcanic centres along hotspot tracks[7] and for sea-floor swells[9]. Thermal plumes probably remain stable because of the ever expanding thermal-conduit width and because of the reduced viscosity contrast across the plume. (At a temperature contrast of 50 °C, the plume interior is initially about an order of magnitude less viscous than the surrounding fluid.) A detailed stability analysis, similar to Whitehead's for chemical plumes[17], is thus warranted for thermal plumes.

Figure 2*e*, *f* show another new observation. Thermal conduit waves (or solitons) are induced by three sudden increases in conduit feed rate. These three blobs show the thermal entrainment expected[11], but the effect of horizontal deflection causes a strongly asymmetrical pattern in the original source material as the blobs rise. If such hot blobs are considered as hotspot sources, then the original (enriched mantle) plume material would be least diluted in the 'downstream' direction of plate motion with the most strongly diluted material toward the 'upstream' side of the volcanic centre.

The most conspicuous evidence for the effects we have discussed is found in the geochemistry of basaltic lavas from the Galapagos hotspot, for which Geist *et al.*[18] have described a puzzling open-horseshoe pattern of strontium isotope enrichment. This pattern is thought to reflect source heterogeneity, because variations in trace-element concentrations, which reflect differences in melting and fractionation processes, are not well correlated with the variations in the isotope ratios. Geist *et al.*[18] proposed that this source heterogeneity resulted from thermal entrainment by a persistent hot diapir beneath the lithosphere, with a depleted (upper mantle) core surrounded by an enriched (lower mantle) torus. The least-enriched basalts are found toward the downstream (east) side of the Galapagos archipelago, however, which is just the opposite pattern shown in our experiments (Fig. 2*f*).

There are other problems with the single-diapir model for the Galapagos hotspot. First, a solitary diapir would obviously not remain stationary beneath the lithosphere, but would be advected along with the plate motion. This is inconsistent with the fact that the volcanism propagates westward relative to the overlying oceanic plate at the expected rate (~5 cm yr^{-1}) for a fixed mantle plume. The second problem is that the continuity of the Cocos and Carnegie Ridges (twin hotspot tracks formed while the Galapagos spreading centre coincided with the Galapagos hotspot) requires long-lived continuity of the Galapagos plume before ~5 Myr.

We suggest an alternative model which might better explain the Galapagos isotope data. Thermal entrainment by a continuous, horizontally deflected plume would result in a spreading V pattern (see Fig. 2*b*, *d*), with the least-enriched (upper mantle) source material toward the downstream side of the hotspot track (as observed). Scaling from the experiment in Fig. 2*d* to the ~150-km-wide plume top needed to explain the width of the Galapagos platform, we find a comparable conduit Rayleigh number of ~200 for an upper-mantle viscosity of 10^{22} P and an original plume excess temperature of ~250 °C. Scaling to the upper-mantle depth of 600 km, a comparable Peclet number of ~300 requires an average upper-mantle shear velocity of ~1-2 cm yr^{-1}. As in Fig. 2*d*, such a plume would consist of only about 35% original source material, with a final temperature excess beneath the lithosphere of ~100 °C. The parameters we have assumed are not well constrained, and we emphasize that our model is speculative. A major field effort is presently underway in the Galapagos to test these ideas, and a more complete set of laboratory experiments will be reported elsewhere.

Our experimental parameters emphasize the true plume width and maximize the degree of dilution or entrainment. Differing degrees of thermal entrainment (or horizontal deflection) may explain some of the variations in the degree of geochemical enrichment observed for different hotspots[19]. Application of these ideas to geochemical data from hotspot tracks such as the Galapagos may help determine whether or not mantle plumes are driven primarily by thermal or compositional buoyancy. ☐

Gravity changes as a precursor to volcanic eruption at Poás volcano, Costa Rica

Hazel Rymer & Geoff Brown

Department of Earth Sciences, Open University, Walton Hall,
Milton Keynes MK7 6AA, UK

MONITORING of gravity changes at active volcanoes has considerable potential for understanding magma-chamber dynamics and for detecting eruptive precursors. The technique essentially aims to identify changes in sub-surface mass or density corresponding to departures from the free-air gradient (FAG) or Bouguer-

corrected (terrain-corrected) FAG (BCFAG), respectively[1,2]. Such gravity changes, of the order of 10–100 μgal, have been reported previously through eruptive periods[3–6]. Here we present a ten-year data set measured at Poás volcano, Costa Rica, in which gravity increases in 1987–1989, relative to both the FAG and the BCFAG, preceded the ash-cloud eruptions of April–May 1989. These results constitute the first unambiguous detection of gravity changes as a precursor to eruption, and we interpret them in terms of the intrusion of an ascending, relatively dense magma body.

The last major eruption at Poás was in 1953, when phreatic activity culminated in the growth of a 30-m-high pyroclastic cone and the formation of an inner crater, both within the old summit crater. Since then, a hot crater lake has absorbed any fluctuations in heat output[7] from the magma feeder pipe by changing in volume, temperatuture and evaporation rate. Microgravity monitoring at Poás began in 1979 and was intensified to include more stations and some elevation control in 1985 (refs 8, 9). Compared with a reference point 2 km south of the active crater, we observed no significant gravity change at the three crater rim or eight flank stations between 1979 and 1983, although intensive monitoring over a 43-day period in 1983 did reveal cyclic variations[8]. We interpreted this phenomenon, observed again in 1985 during more detailed monitoring of sixteen crater stations, in terms of cyclic variations in the degree of vesiculation within the summit magma feeder pipe[9]. Since 1985, we have observed unidirectional gravity changes at crater stations on and around the 1953 cone. Relative elevation measurements, using a theodolite with an infrared electronic distance-measuring device yielding a precision of ∼2 cm, have been made since 1987 so that we could examine the possibility of sub-surface mass changes.

To observe long-term gravity changes, we average the data for each period of observation (typically several days), thus smoothing out any short-period cyclic variations. Uncertainties (which we determine by the reproducibility of difference measurements) are, at worst, up to 40 μgal for data obtained before March 1987, and are <25 μgal after this date because of the use of electronic readout and many more repeat readings[10]. Although there are a few erratic readings in the data set, nevertheless the mean difference between the two instruments is only 28 ± 26 μgal, similar to the uncertainty analysis above (and in ref. 10). The gravity variations relative to the reference point observed between 1979 and 1989 at crater-rim stations (R2A and R7, for example) are irregular and do not show a clear trend (Fig. 1). At crater-bottom stations E1, E3 and D1 (adjacent to the 1953 cone), however, relative gravity has clearly increased since March 1987. Indeed, total changes at the three stations on the 1953 pyroclastic cone (Fig. 1 inset) have been of the order of 200 μgal between 1985 and 1989. On the north side of the crater lake, only station D3 has experienced unambiguous decreases in the relative gravity from 1985 onwards. Because the gravity changes at stations E5–D1 (Fig. 1) are more than several times the size of the uncertainties involved, and two Lacoste and Romberg meters have been used (since 1987), the increases are undoubtedly genuine.

To evaluate the Bouguer-corrected free-air effect on gravity we assume a typical density. Measurements of surface rocks in the crater area yield densities of ∼2.67 Mg m^{-3} (for lavas) falling to ∼1.17 Mg m^{-3} for pyroclastic ashes, giving an estimated average of ∼2.2 Mg m^{-3} for the shallow and surface materials. For a given elevation change, assuming the usual free-air gradient and no density change, gravity will vary according to

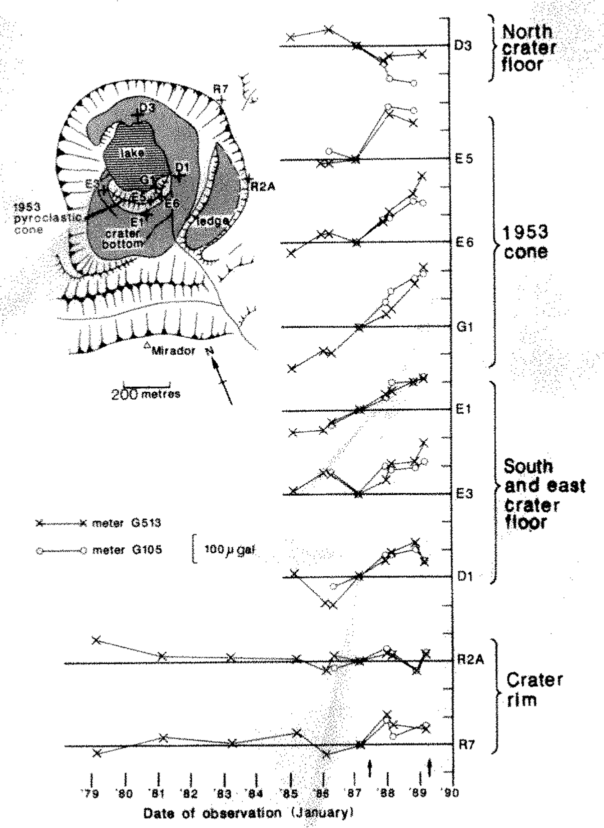

FIG. 1 Gravity variations using Lacoste and Romberg gravity meter G513 and (since 1987) G105 are expressed relative to the value at a reference point on the volcano flank for two crater-rim and seven crater-bottom stations with good gravity and elevation control. Each data point represents the average value obtained during 3–10 survey days. For details of errors, see text. The two arrows at the bottom of the figure indicate periods of dramatic change in surface activity. Note that if crater-bottom (or rim) gravity data were affected by the recent decrease in lake level, a relative decrease in gravity would be observed (as at D3, which seems to be remote from the centre-of-mass increase). Because all stations except D3 experience a gravity increase, the effect of the falling lake and water table is either negligible or at least small—except on the northern lake side—compared with another opposite effect causing a gravity increase. The inset shows station locations.

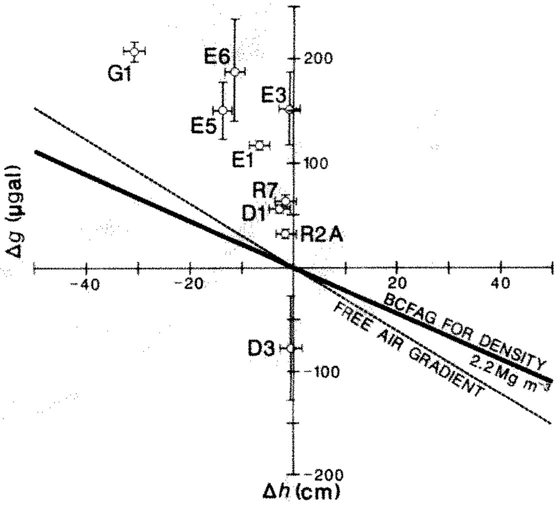

FIG. 2 Plot of the change in gravity against the change in elevation with the theoretical FAG and BCFAG marked for reference[1,2]. The mean gravity change as recorded by the two instruments is plotted with error bars reflecting the difference between the two meters for the 1987–1989 comparison (see Fig. 1, where the two meters differ by 28 ± 26 μgal). The stations read most frequently, which are G1, D1, E1 and R2A, have the smallest error bars on this basis. Errors in elevation differences are estimated as ±2 cm. An overall gravity increase is observed between March 1987 and March 1989 at all crater stations, except D3, even after account is taken of deflation, because all points plot above the FAG and BCFAG lines. The residual gravity increase over this period beneath stations E1, E3, E5, E6 and G1 is 100–150 μgal; see text for interpretation of the corresponding shallow mass increase.

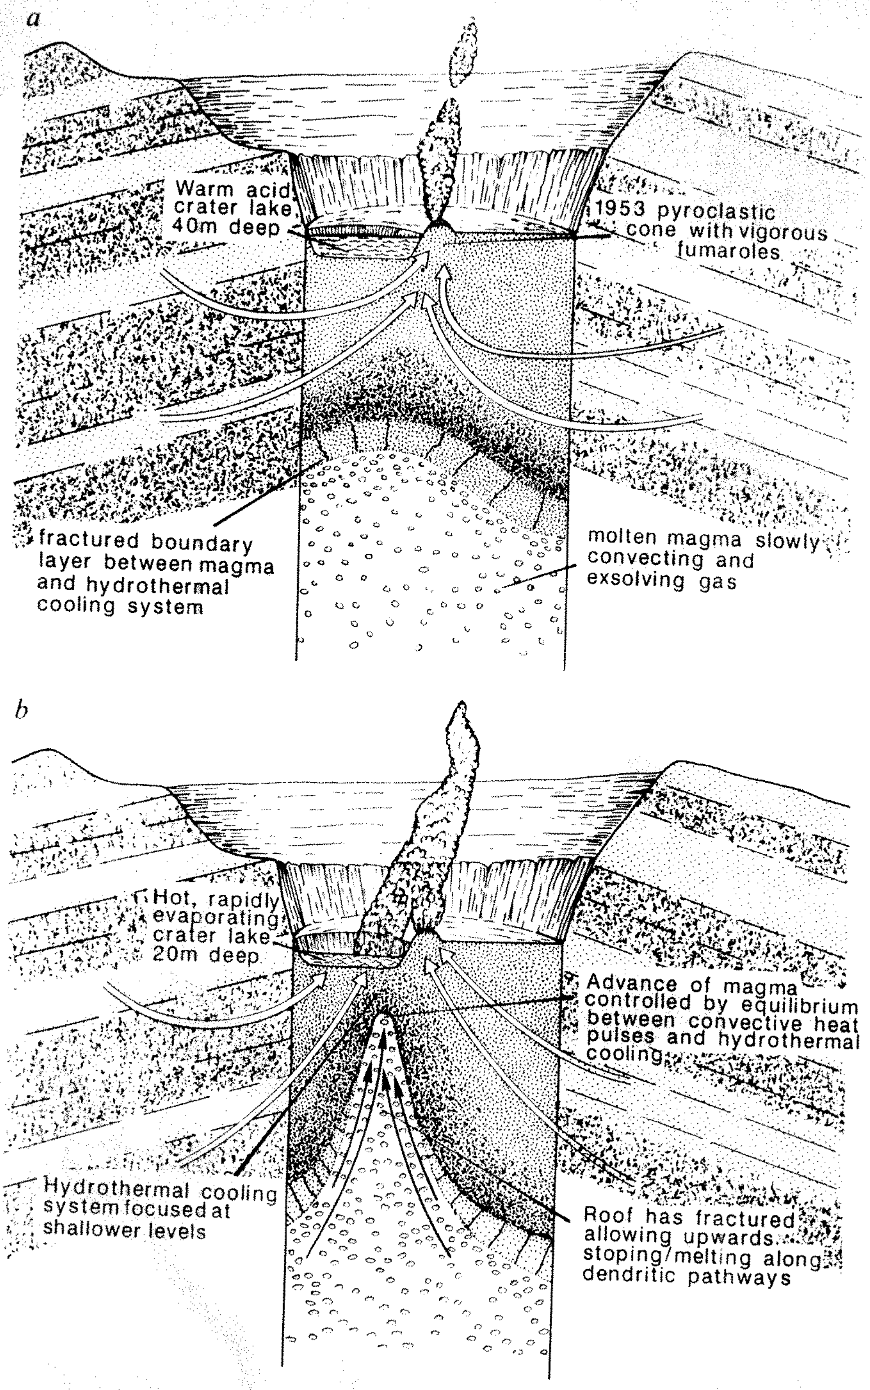

a

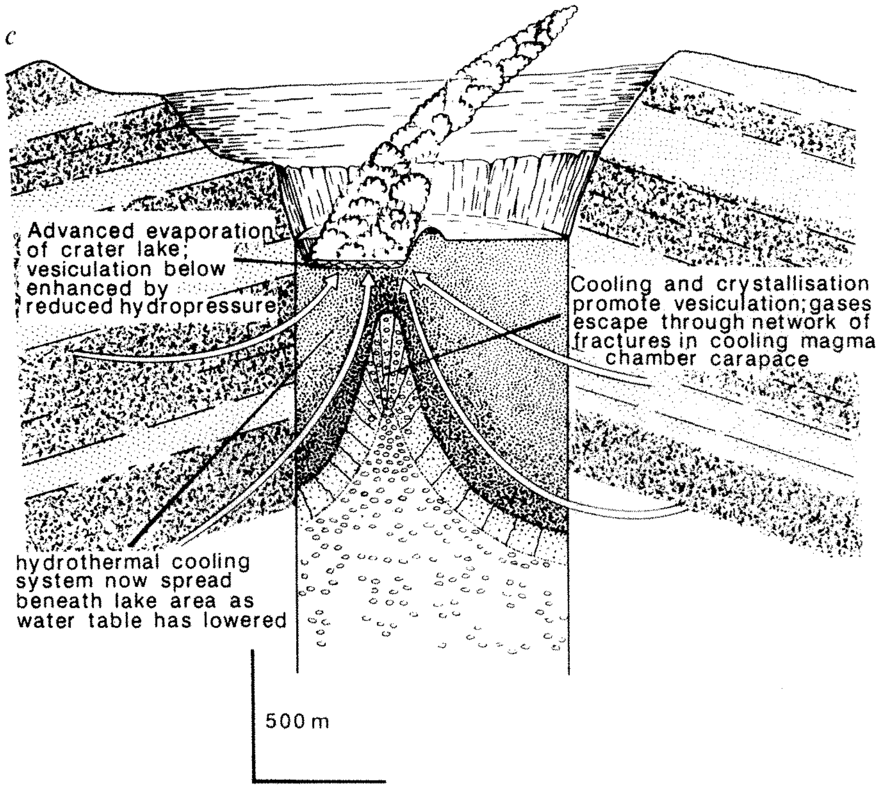
1953 pyroclastic cone with vigorous fumaroles
fractured boundary layer between magma and hydrothermal cooling system
molten magma slowly convecting and exsolving gas
b
Hot, rapidly evaporating crater lake 20m deep
Advance of magma controlled by equilibrium between convective heat pulses and hydrothermal cooling
Hydrothermal cooling system focused at shallower levels
Roof has fractured allowing upwards stoping/melting along dendritic pathways

FIG. 3 Schematic north–south cross-sections of Poás volcano summit and postulated evolution (*a–c*) of the magma chamber and its upper boundary layer. Within this layer, heat is removed by the hydrothermal steam-water system from the frozen, fractured cap of the partially molten magma body, initially at ~500 m depth. *a* shows the steady-state 1985 model developed in refs 7 and 16; by 1987 (*b*) we propose that the boundary layer had fractured extensively, allowing fingers of magma to ascend to a new equilibrium level where their upwards progress was halted by the increasingly efficient cooling system; in late 1988 (*c*), as pressure on the cooling magma system reduced and crystallization advanced, the collection of volcanic gases within the magma and their discharge through an extended fractured boundary layer is envisaged.

the BCFAG. The predicted BCFAG for this density is −216 μgal m^{-1} and we attribute (to a first approximation) observations that fall away from this line to sub-surface density changes[1-6]. This simple model requires change to occur only along an extensive horizontal slab; more complicated regions of dilatation/contraction do not follow a linear Δg–Δh relationship[2]. We present data for March 1987–March 1989 in Fig. 2; although there is some scatter, it is clear that overall subsidence of the crater rim and bottom region (maximum of 31 cm, measured relative to the Mirador benchmark shown in Fig. 1 inset) was accompanied by an 'excess' gravity increase. A net gravity increase above the BCFAG during a period of elevation decrease reflects an overall sub-surface density increase and a net gravity increase above the FAG reflects an overall mass increase. The excess gravity increase above both the BCFAG and FAG is smallest on the crater rim and largest on the pyroclastic cone, which is also the region of maximum deflation (especially at station G1). For stations E1, E3, E5, E6 and G1 the excess gravity increase above the FAG is 100–150 μgal (Fig. 2).

Records of historical activity at Poás[11,12] show that the recent geysering and disappearance of the lake, culminating in ash eruptions (as in 1989) are following a similar pattern to the rather poorly documented 1828, 1834, 1910 and 1953 eruptions. A warm (~40 °C) acidic crater lake remains apparently quite stable for a number of years, then shrinks dramatically and disappears during phreatic activity, which often culminates in a relatively minor ash-pyroclastic eruption. Before the present activity the Poás crater lake had maintained dynamic equilibrium since the late 1970s (refs 7, 13), however the lake level began to fall slowly in 1982 and by March 1989 it had fallen by a total of 40 m, 32 m of which occurred between March 1987 and March 1989 (refs 7, 14). Changes in the style of surface activity are marked on Fig. 1 at June 1987 when geyser eruptions began[14] and April 1989 when a 2-km-high ash cloud (reworked material) was erupted periodically until the crater lake was



c

re-established in mid-May. Interestingly, we observe the most significant gravity changes at stations on the 1953 cone both before 1987 and during the 1987–1989 period. Elevation data are not available before 1987, but gravity data for most crater stations show a similar trend from 1985 onwards, so assuming that elevation changes were no greater than those since 1987, the magnitude of the excess gravity increase over the four-year 1985–1989 period is estimated at ~200 μgal over an area of $\sim 10^4\ \mathrm{m}^2$. By applying Gauss' theorem and assuming the new mass has a density 2.67 $\mathrm{Mg\ m}^{-3}$ (the same as the erupted lava) we calculate a total sub-surface mass increase of $\sim 10^8$ kg.

An overall density increase beneath the crater area of volcanoes like Poás is usually interpreted[1,3] either in terms of magma devesiculation, or the collapse of voids, or the ascent of relatively dense magma into low-density agglomerates and ashes. In view of the 1987–1989 deflation, void collapse is a possibility, but because the power output at Poás almost doubled between 1985 and 1988 (ref. 7), we prefer a model involving upwards ascent of magma. As the 1985–1987 gravity increase is only observed at stations on and close to the 1953 cone, and thereafter the effect is largest at these stations, the depth of the causative intrusion using a half-width approximation must be shallow, probably <200 m. The intrusion is not necessarily directly beneath the cone, because gravity increases more to the north (that is, from E1 to E6 to G1); it may be centred on the fault at the north side of the cone or even further north beneath the lake (where we have no data). Given the steady-state starting situation in Fig. 3*a* (refs 7–9), we suggest that a small dendritic intrusion rose (Fig. 3*b*) from a region of partial melt ~500 m beneath the crater[9] through cracking of the magma-chamber roof zone[15], perhaps because hydrothermal cooling was unable to extract heat at the rate being supplied from below[7]. As the magma advanced it drove off ground waters producing elevated fumarole temperatures (500 °C measured on the cone in 1985). As the lake level fell because of more rapid evaporation, the water table would become lower (which may account for the gravity decreases observed at station D3) and eventually the fumaroles on the cone would have cooled and almost disappeared as heat output switched to the crater lake (the bottom of which is some 30 m below the base of the cone; Fig. 3*c*). As the cone cooled from ~500 °C (1985) to ~100 °C (1988), it would be expected to contract. The cone consists of vesiculated, blocky and altered andesite lava, with a thermal expansivity of $\sim 5 \times 10^{-5}\ {}^\circ\mathrm{C}^{-1}$, so a drop of 400 °C could easily result in 1% contraction of the 30-m-high cone (note the 31-cm deflation at station G1, Fig. 2). Deflation would also accompany the fall in water vapour pressure within the edifice as the water table fell below the base of the cone to its early 1989 position just above the lake bottom (Fig. 3*c*).

This is the first unambiguous record of gravity changes occurring before an eruption (in this case, the April–May 1989 ash cloud); it highlights the potential of microgravity monitoring as a predictive technique in the surveillance of active volcanoes. The power output at Poás is calculated to have increased from ~160 ± 50 MW to ~265 ± 100 MW between 1985 and 1988 (ref. 7) and this is consistent with the injection of shallow magma beneath the crater lake (Fig. 3*b*). The possibility of a major pyroclastic eruption involving juvenile material, resulting from the advanced buildup of magmatic gas pressure[8] in the area of the pyroclastic cone and lake, cannot be ruled out. ☐

A helium isotope transect along the Indonesian archipelago

D. R. Hilton* & H. Craig

Isotope Laboratory, Scripps Institution of Oceanography,
University of California, San Diego, La Jolla, California 92093, USA
* Present address: Free University of Berlin, FB 24, FR Geochemie,
Boltzmannstrasse 18-20 1000 Berlin 33, FRG

HELIUM isotope studies[1,2] have identified the Banda arc section of the Indonesian archipelago as the only circum-Pacific volcanic arc with $^3He/^4He$ ratios significantly lower than the common ratio in mid-ocean-ridge basalts (MORB). In eleven of twelve circum-Pacific arcs, MORB-like $^3He/^4He$ ratios show that helium in these volcanic terrains is dominantly primordial helium from the mantle wedge above the sinking slab, rather than radiogenic helium from subducting oceanic crust or sediments. Only in the Banda arc have significantly lower ratios been observed, corresponding to as much as 80% radiogenic helium from subducting continental material[2]. We now report $^3He/^4He$ measurements along a 1,800-km section of the Sunda arc, a region of underthrust oceanic lithosphere, showing MORB-like ratios from western Java to a surprisingly sharp transition zone centred on Lomblen Island, where the low ratios of the Banda arc begin. Our results confirm the prediction[2] that Sunda arc volcanoes should have MORB-like $^3He/^4He$ ratios, with a well-defined transition to the much lower Banda arc ratios near Lewotolo volcano, and demonstrate a remarkable linkage of helium isotope variations with tectonic processes not readily discernible with trace elements or other isotopes.

The Indonesian arc system is a study in contrasting tectonics[3-5]. In the Sunda arc on the west, oceanic lithosphere of the Austral-Indian plate is subducting northward along the Java Trench under the continental margin of the Eurasian plate. On the east the contiguous Banda arc is a reciprocal system with northward subduction of the Australian continental margin, also on the Austral-Indian plate, under the Banda Sea. Both arcs include typical arc volcanics and high-potassium calc-alkaline lavas[6-8]. The Sunda arc however, along 2,000 km from western Java to Lomblen, is punctuated at ~650-km intervals by leucite-bearing potassium-rich volcanoes[9], such as Muriah on Java[10], Sangenges and Soromundi on Sumbawa[11] and Batu Tara north of Flores[9]. Strontium and neodymium isotope data[9-16] are the primary discriminants for the two arcs: Sunda arc lavas lie within the mantle-array region defined by other island arcs, whereas Banda arc lavas are displaced toward more radiogenic Sr and Nd ratios, indicating mixing with sialic crustal material[17]. The isotope data and tectonic interpretation are thus consistent with one another and indicate that the Banda arc is the only volcanic island arc and continent collision zone in which underthrusting of continental crust is occurring.

We measured the $^3He/^4He$ ratios of volcanic gases from nine sites at five active volcanoes on Java, Flores and Lomblen: helium in phenocrysts from recent lavas was measured at three other volcanoes on Bali, Sumbawa and Batu Tara (Komba). In Fig. 1 and Table 1 we give the $^3He/^4He$ ratios at each site; data from our previous study[2] of Banda arc volcanoes are also included. Lewotolo volcano was resampled (at different sites) with identical results. The most important results show that the Sunda arc volcanoes along a 1,500-km section from western Java to central Flores (Tankguban Parahu, Merapi, Batur, Sangeang Api and Keli Mutu) have $^3He/^4He$ ratios of $R/R_A = 5.7\text{-}8.2$ (where R_A is the $^3He/^4He$ ratio of air), almost exactly the range in the circum-Pacific arc systems studied previously[2]. Compared to the mean MORB ratio ($R/R_A = 8 \pm 1$) and radiogenic or 'crustal' He ($R/R_A < 0.02$), these volcanic ratios correspond to a mantle (MORB) helium fraction of 70-100%. The Java-Bali-Sumbawa-Flores $^3He/^4He$ ratios are thus very different from the Pantar and Banda arc ratios ($R/R_A = 1.1\text{-}1.7$) in which the helium is in every case more than 80% of radiogenic origin. Because the Banda arc is unique among volcanic-arc terrains in emitting predominantly radiogenic helium, and is unique in having collided with, and been underthrust by, continental crustal material, it is evident that the Banda arc helium is derived from the subducting Australian crustal material.

Between the low R/R_A volcano Sirung on the island of Pantar and the first active volcano of the Banda arc, Damar, a 500-km inactive segment has been interposed by completion of the suture between the Banda arc and the Australian continental margin and cessation of active underthrusting[3,4]. The transition from mantle to radiogenic helium emission is not in the Banda arc itself, nor is it across the volcanic quiet segment: the actual $^3He/^4He$ transition zone is the narrow 200-km section between Egon volcano on the west, at the narrowest width of eastern Flores, and Sirung volcano on the east, at the southern tip of Pantar[18]. These two volcanoes have the lowest $^3He/^4He$ ratios in the arcs ($R/R_A = 1.25$ and ~ 1.1), but between them, at nearly the midpoint of the transition zone, Lewotolo volcano within the arc and Batu Tara 53 km to the north in the Banda Sea have identical elevated $^3He/^4He$ ratios of 3.4 and 3.6 R_A. The $^3He/^4He$ structure of this zone is thus complex and deserves further study.

In Fig. 2 we compare the $^{87}Sr/^{86}Sr$ profile (see refs 6, 10 and 19) and the $^3He/^4He$ ratios along the 2,800-km section from west Java to Serua at the eastern extremity of the Banda arc. The sharp drop in $^3He/^4He$ ratio at the transition zone (6.0 R_A to 1.25 R_A in only 70 km from Keli Mutu to Egon) is in marked contrast to the approximately linear increase in $^{87}Sr/^{86}Sr$ over the ~750-km section from Bali to Egon, and even more so for the 1,500-km increase from Bali to Damar. That is to say, the along-strike transition from oceanic lithosphere to continental crustal material on the downgoing Austral-Indian plate, from the ^3He measurements, seems to be extremely sharp. Katili and

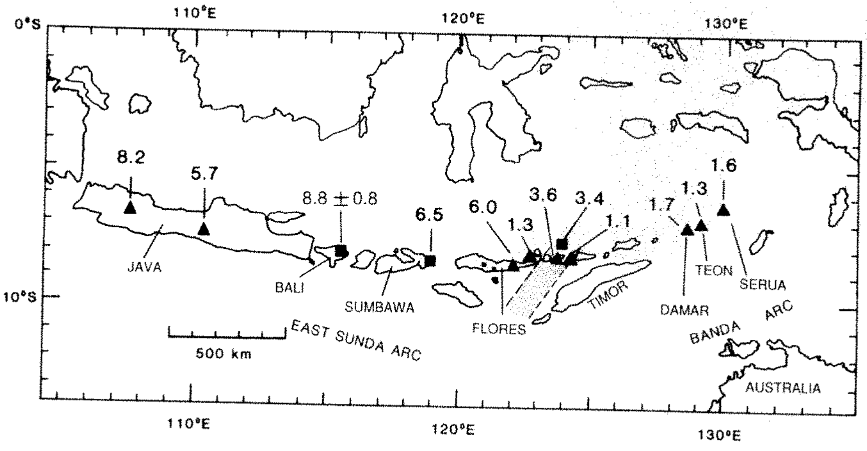

FIG. 1 Helium isotope ratios (relative to atmospheric helium) in volcanic gases (▲) and lavas (■) in the Indonesian volcanic arcs. From west to east in the Sunda arc the volcanoes are Tangkuban Parahu and Merapi on Java, Batur on Bali, Sangeang Api on Sumbawa, Keli Mutu and Egon on Flores, Lewotolo on Lomblen, Batu Tara (a potassium-rich leucitic volcano) in the Banda Sea 53 km north of Lewotolo, and Sirung on Pantar. Between the active Sunda and Banda volcanoes is a 500-km volcanoseismic 'quiet sector' extending from Pantar to Damar. Dashed lines correspond to proposed faults in the Savu Basin (stippled): the eastern fault runs east of Pantar; the western fault is assumed to run east of Flores[19] or west of Pantar[24,25]. Volcano names follow the usage of Simkin *et al.*[28].

We used a Clarke-type ^{3}He mass spectrometer (GAD) for the ^{3}He/^{4}He measurements[1,2]. Helium was separated from neon on activated charcoal at 37 K and measured relative to the Yellowstone 'Murdering Mudpots' standard ($R/R_A = 16.45$). Neon was also measured and the He/Ne ratios (column 5) were used to correct the measured ratios (column 4), assuming all Ne to be atmospheric. R_c is the corrected ratio and R_A is the ratio in atmospheric helium. Precision of the ^{3}He/^{4}He ratios is 1%. The helium was extracted from phenocrysts in recent lavas by vacuum crushing: [He] is the measured He concentration. Blank contribution to ^{3}He was 0.7% (Sangeang Api), 7% (Batur) and 10% (Batu Tara). Only 0.5 g of olivine was available for the Batur analysis: a 10% uncertainty is assigned to the ratio of this sample.

* Sample key: sf, summit fumarole; ff, flank fumarole; as, gas from acid spring; wa, hotspring water sample; ol, cpx, olivine and pyroxene phenocrysts in lavas. Lava samples: Batur, mixture of 1904 and 1974 flows; Sangeang Api, xenolith or cumulate sample 'B4'[13] (also R. Varne No. 48083) from 1911 lahar on south-west coast; Batu Tara, potassium-rich leucite basanite[9,16] (R. Varne No. 67130).

† NC, Non-condensable gases. Samples were collected in evacuated 1720-glass flasks (50-ml volume) with vacuum stopcocks. Analyses were made using thermal conductivity gas chromatography, after liquid nitrogen separation of CO_2, H_2S and SO_2 (data to be reported elsewhere). Hydrogen was observed only qualitatively in our system: significant amounts of H_2 were present in the Tangkuban Parahu and Lewotolo samples and traces were seen in the Merapi analyses. Methane was found in gases from Tangkuban Parahu (6.2% of NC), Lewotolo (2.4% of NC) and Damar ff (0.3% of NC).

‡ The ^{3}He and He/Ne data for these samples are from our previous work[2]. (He/NC ratios tabulated for these samples were calculated incorrectly). The ^{3}He/^{4}He ratio for Sirung is questionable because of the large amount of air helium in this sample.

Hartono[5] placed this transition zone "in the eastern part of Flores Island", in close agreement with the position located here by helium isotope ratios.

Within the transition zone the ^{3}He structure is marked by higher R/R_A values at Lewotolo and Batu Tara in the centre and more radiogenic ratios at the two volcanoes, Egon and Sirung, that define the edges. Although this pattern is not yet explained there are a number of possibilities. Wheller *et al.*[9] identified three sectors along the Sunda arc from Java to Lomblen that are terminated by the potassium-rich, leucite-bearing volcanoes noted above. These mark the ends of volcanic sectors with progressively increasing K/Si ratios, after which the series begins again in the next sector. Their 'Flores sector' is terminated by the potassium-rich volcano Batu Tara that, with Lewotolo—a high-potassium volcano—marks the centre of the ^{3}He transition zone (Fig. 2). Wheller *et al.* show that K, Si, and ^{87}Sr/^{86}Sr data for Sunda-Banda lavas require, in addition to ocean mantle and continental crust sources, a third, potassium-rich, component. This component may be the source of the elevated ^{3}He/^{4}He ratios in the central part of the ^{3}He transition zone.

An alternative explanation may lie in the relationship between volcanism and tectonics in the Savu Basin, a depression with large negative gravity anomalies which is floored by oceanic crust and contains the ^{3}He transition zone between the islands of Flores and Pantar. Nishimura *et al.*[20] showed that the transition zone is a discontinuity marked by offsets of gravity anomaly, earthquake patterns, submarine morphology, strike of the volcanic arc and chemistry of Quaternary lavas. McBride and Karig[21] interpreted the gravity data as evidence for the subduction of continental material into the mantle below the basin, and Eva *et al.*[22] have proposed that the strike of the subducting slab is parallel to Timor in the eastern part of the basin, resulting in transcurrent faulting such as the Pantar fracture zone deduced from seismic data[23]. Silver *et al.*[24] and van Bergen *et al.*[25] show cross-arc faults both east and west of Pantar in the eastern part of the transition zone, whereas Varekamp *et al.*[19] propose that the Savu Basin is bounded east and west by NNE to SSW transcurrent faults crossing the arc tangent to the east side of Pantar and the eastern end of Flores, almost exactly the arc section outlined by the ^{3}He transition zone. Such cross-arc fault patterns might provide zones for trapping subducted continental material at the boundaries of the Savu Basin while allowing less-contaminated mantle material to erupt in the centre of the basin

Perhaps the most difficult question posed by our data is the very low ^{3}He/^{4}He ratio (1.25 R_A) at Egon Volcano on eastern Flores. Hamilton (ref. 4, Figs 53 and 78) indicates that continen-

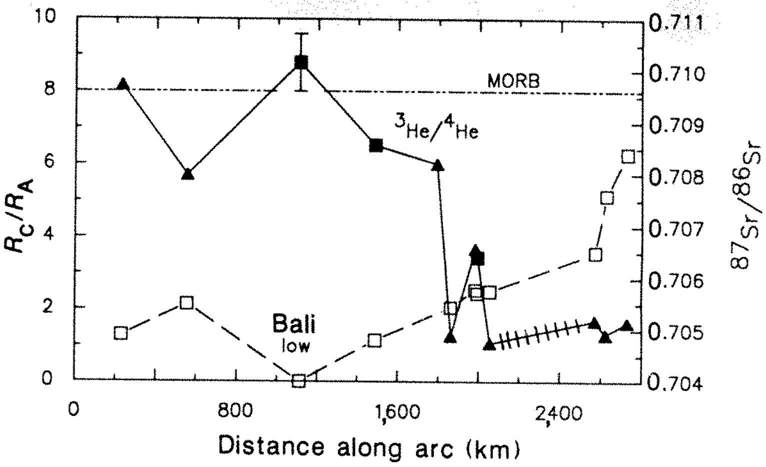

FIG. 2 ^{3}He/^{4}He and ^{87}Sr/^{86}Sr ratios along the Sunda–Banda arcs from the western end of Java. Symbols as in Fig. 1: geographic coordinates are from ref. 18. MORB, ^{3}He/^{4}He ratio ($R/R_A = 8 \pm 1$) in mid-ocean-ridge-basalt helium[2,27]. Sr isotope data (open squares) are from refs 8–16 (the dashed lines are profiles from refs 6, 10 and 19). The lowest (least radiogenic) ^{87}Sr/^{86}Sr ratios are in lavas from Bali: eastward from Bali the Sr ratios increase monotonically to the sharp increase in slope at the end of the Banda quiet zone (cross-hatched). The ^{3}He/^{4}He ratios, however, drop very sharply (factor of five) in the 68-km span from Keli Mutu to Egon. The antithetic correlation of Sr and He ratios in the Sunda arc is consistent with simple two-component mixing. Helium data from two sources, fumarole gases and lava phenocrysts, are compared with the Sr isotope ratios. The only detailed comparison so far of such sources is of data from the Mariana arc[2]: in this area helium from one clinopyroxene and two olivine samples from two seamounts and from a hotspring on Agrigan volcano[1,2] had identical ^{3}He/^{4}He ratios. But it was also found[2] that 'flank' fumaroles on large volcanoes such as Makushin tend to have lower ^{3}He/^{4}He ratios than 'summit' fumaroles: thus caution is necessary when flank fumaroles are compared with other sources.

tal crust is subducted to a depth of, at most, ~40 km below the Savu Basin north of western Timor, and so that only old (Jurassic) oceanic crust lies below Flores (and Pantar). The previous studies of arc helium[1,2] show, however, that subduction of oceanic crust does not result in low (radiogenic) ^{3}He/^{4}He ratios, so that unless the Egon samples have been contaminated with near-surface radiogenic helium, a source of continental material is required at depth. Hamilton (personal communication) suggests that subducting sediments from abyssal fans north-west of Australia, derived from Precambrian crust, could well be present below eastern Flores and the transition zone to supply the observed helium. But McCaffrey *et al.*[26], who carried out a detailed microearthquake study in the Savu Basin, found a sharp seismic boundary between oceanic and continental crust striking ~N 65° E between Timor and Pantar, which they interpreted as a bend in the subducting slab of continental crust, extending to a depth of 150 km. This would put continental material beneath Pantar and probably beneath Solor (ref. 4, Fig. 78) at the eastern end of Flores. Our data are not sufficient for us to choose between these interpretations of the geophysical results but, with more extensive sampling across the ^{3}He transition zone, it may be possible to track the subducted continental crust across this zone.

Figure 2 also shows the striking antithetic correlation between helium and strontium isotopes along the Sunda arc. A similar correlation has been observed in restricted regions of the Mid-Atlantic Ridge[27], but this is the first clear case for two-component mixing of helium and strontium over a major segment of an active plate boundary. The antithetic He–Sr relationship is not present in the Banda arc: ^{3}He/^{4}He ratios are almost constant whereas ^{87}Sr/^{86}Sr ratios continue to increase along the arc. The lowest ^{87}Sr/^{86}Sr ratio in in the Indonesian arcs is ~0.7040 in the lavas of Bali[10]: these define a 'Bali low' in Fig. 2, close to the value for the MORB-like endmember, and correspond to an increased ^{3}He/^{4}He ratio: a 'Bali high' relative to the rest of the arc. □

THE aquifer system of the Great Hungarian Plain covers 50,000 km^2 and contains helium with an isotopic composition that indicates regional loss of both radiogenic-crustal and mantle-derived helium. Mantle-derived melts must be present at depth over much of the region. Here we show that the mantle helium flux through the basin may be supported by the addition of 20 m of melt per Myr. Considerations of hydrogeology and helium abundances show that the rate of loss of radiogenic helium from the basin may exceed the crustal helium production rate.

All continental ground waters contain small amounts of dissolved helium, often considerably in excess of the equilibrium saturation value. Most of this helium is generated by radioactivity and other nuclear processes within the crust. Such helium is characterized by its isotopic composition,

$R = {}^3\text{He}/{}^4\text{He} \sim 10^{-8}$. In some areas, however, volatiles escape from the mantle or lower crust and accumulate in the groundwater system. The presence of another helium component derived from the mantle may be established by its distinctive isotopic composition ($R \simeq 10^{-5}$).

In principle the fluxes of both mantle-derived helium and radiogenic crustal helium may be estimated if the characteristics of the aquifer are known. An ideal case would be a regional groundwater system of known area and well defined limits, for which the recharge and discharge were known and in balance. For such a result to be regionally significant, the extent of the aquifer system should be large by comparison with the thickness of the crust and direct losses of gas from the crust to the atmosphere should be small. In many respects the Great Hungarian Plain (GHP) within the Pannonian Basin meets these requirements, although there is no way of knowing how much gas is lost directly to the atmosphere and what proportion is trapped by the ground water.

The Pannonian basin in eastern Central Europe is an oval sedimentary basin, with a diameter of ~500 km (Fig. 1*a*). The sedimentary fill comprises early Miocene, Pliocene and Quaternary deposits that are predominantly clastic, often with significant amounts of rhyolite tuffs and lava flows[1]. The basin is bounded by the Alps, Carpathians and Dinarides, and constitutes a closed hydrological system[2,3]. The GHP forms the eastern part of the Pannonian basin and is a remarkably flat area between 80 and 200 m above sea level.

The Quaternary consists of poorly consolidated sand and clayey sand deposits (100–600 m) overlying 500–1,800 m of Pliocene lacustrine and fluviatile alternating sands and clays. The underlying Miocene is a thick (up to 4,000 m) shale-rich sequence overlying a basement that varies in age from late Palaeozoic to Mesozoic and, locally, to Oligocene. The structural development of the GHP has been controlled by a set of transcurrent faults striking east-north-east to west-south-west, and associated normal faults[4,5].

There are two water flow regimes of regional extent in the GHP[2,6] (Fig. 2). The upper flow regime is essentially within the Quaternary. Meteoric water recharge occurs at topographic highs (Figs 1*b* and 2) and discharge occurs in topographic lows, particularly into the base of the Tisza River. A lower, dominantly connate, saline-water flow regime (Fig. 2) exists within the Pliocene and part of the Miocene. The Pannonian Basin is artesian, with the upward flow controlled by overpressuring of deeper waters. Some communication between the two flow regimes occurs in the central part of the GHP (Fig. 2).

Hydrological observations indicate[5-8] that the total groundwater flow in the GHP is $\sim 35\ \text{m}^3\ \text{s}^{-1}$. This value is based on some thousand pressure observations and permeability estimates from pumping experiments in boreholes. This is consistent with a previous estimate[9] of $17 \pm 11\ \text{m}^3\ \text{s}^{-1}$ for the discharge of subsurface water into the Tisza River system, which provides a lower limit for the discharge of the basin system as a whole. This latter estimate was derived from the progressive dilution of tritiated Tisza river water by non-tritiated sub-surface water over a distance of some 300 km.

The locations of samples analysed either in Cambridge or in Heidelberg are shown in Fig. 1*b* and the results summarized in Table 1. We collected the samples in conventional clamped annealed copper tubes and analysed them using very similar techniques. The methods used in Cambridge have been described previously[10]. We estimate associated experimental uncertainties to be ≤10% for helium abundances and ≤3% for isotope ratios.

Comparison of Table 1 with Fig. 1*b* shows that all samples contain more helium than the normal air saturation value ($4.64 \times 10^{-8}\ \text{cm}^3\ \text{g}^{-1}$ at 10 °C) and that the excess increases with distance from the recharge area and reaches a maximum two to three orders of magnitude higher than the saturation value. For some of the Pliocene waters we consider the measured value to be only a lower limit as their very low neon contents indicate that they have undergone degassing at some stage.

We obtain a crude estimate of the helium content of the discharging waters by averaging the values measured in Quaternary waters of the discharge zone. As far as we know, the Pliocene waters do not discharge directly to the surface but first mix with the overlying Quaternary waters.

The samples with the highest concentrations come from the central part of the discharge zone and may be the most representative of the helium contents of waters on their return to the surface. If so the simple average, $6.3 \times 10^{-6}\ \text{cm}^3\ \text{g}^{-1}$, is a lower limiting value. This represents the helium that has been flushed from the rocks through which the waters have passed on their way from recharge to discharge. The R/R_A values where R_A is the ratio for the atmospheric standard given in Table 1 show that although most of the helium is radiogenic

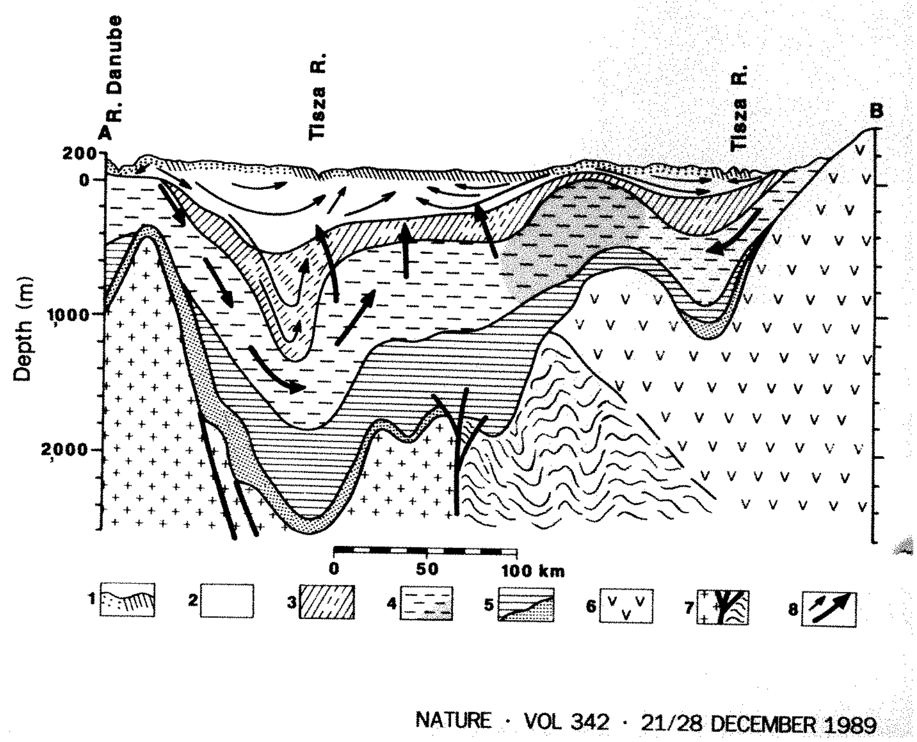

FIG. 2 Generalized cross-section to show the water flow regimes in the sedimentary rocks of the Great Hungarian Plain. The section crosses in south-west/north-east direction the area of Fig. 1*b*. Key: 1, permeable and impermeable deposits at the surface; 2, highly permeable Quaternary beds; 3, Upper Pliocene consisting of impervious and permeable layers; 4, Pliocene sequence of permeable rocks containing fossil sea water and fresh water; 5, late and middle Miocene, mostly aquiclude; 6, late and middle Miocene volcanic rocks; 7, basement of the sedimentary basin consisting of Mesozoic or older rocks and their tectonic contact with Palaeogene flysch; 8, water flow direction in the upper aquifer (thin arrow) and lower aquifer (thick arrow).

* Data from ref. 12.

† Total helium content (mantle-derived component in parentheses), assigned uncertainty ±10%.

‡ Total neon content, assigned uncertainty ±20%.

§ Measured $^3He/^4He$ ratio relative to an atmospheric standard.

($R_A=1.4\times10^{-6}$), corrected for atmospheric component using measured neon concentration following the method in ref. 21.

Values uncorrected for atmospheric component because of lack of neon concentration data.

ow neon concentration indicates some helium depletion.

and probably of crustal origin a small but variable amount must in every case be derived from the mantle. Assuming a value of $R/R_A = 8.0$ for mantle helium the proportion varies from 1 to 16%.

We consider the origin and significance of these components separately. All ground waters from the Pannonian Basin analysed for helium isotopes so far[11,12] (Table 1) have R/R_A values exceeding the radiogenic production ratio for crustal helium. This is also true for over one hundred other analyses we have made elsewhere in Hungary[13]. We consider the excess ^{3}He to be mantle derived and to be pervasively invading the crust, presumably along with other volatiles, over much of the Pannonian Basin. We obtain a total flow of 15 $cm^3 s^{-1}$ (STP) for mantle-derived helium through the GHP from the product of the average mantle helium content of Quaternary discharge waters (Table 1) and the water flow rate (35 $m^3 s^{-1}$). Over the 5×10^4-km^2 area of the GHP the 15 $cm^3 s^{-1}$ mantle helium flow rate corresponds to $\sim 8 \times 10^4$ atom ^{3}He $m^{-2} s^{-1}$. This estimate is necessarily crude, because of the uncertainty in the average mantle helium content of the aquifer, but for the reasons given earlier it probably represents a lower limit and it does provide a useful comparison with the globally averaged mantle ^{3}He flux from the ocean ridges of 4×10^4 atom $m^{-2} s^{-1}$. This is several orders of magnitude higher than in stable, atectonic continental areas[14,15].

Mantle helium has been shown to escape through the crust over much of southern and western Europe[14,16,17]. It was argued that the most plausible means of maintaining such a flux of mantle volatiles was by the emplacement of small volumes of mantle melt in the lower crust, but over a much wider area than the surface volcanic manifestations indicate. Surface Plio-Pleistocene basaltic volcanics are present only sporadically in Hungary such as in the Little Hungarian Plain to the west of the area studied here, but have also been recorded from a borehole in the Great Hungarian Plain[18].

The amount of melt addition beneath the Pannonian Basin is uncertain and could be very small. Because helium behaves as a highly incompatible element and fractionates into the first few per cent of partial melt, the total amount of helium extracted by melting does not depend greatly on the size of the melt fraction. For example, at ocean ridges $\sim 4 \times 10^{-3}$ mol of helium ($R/R_A \sim 8$) are released from the mantle for every cubic metre of basaltic ocean crust formed. If the mantle helium leaking from the Pannonian Basin is supported by basalt with a similar concentration of helium this would require[14] the addition to the crust of $\sim$110 m of basalt per million years. In a sub-continental environment, however, large melt fractions (for example, 10%) such as those at spreading ridges are unlikely and for a 2% melt fraction, which is more likely given the alkalic nature of Plio-Pleistocene basalts in the Pannonian Basin[18], the rate of addition would be 20 m Myr^{-1}.

The greater part (>90%) of the helium contained in the aquifer system is radiogenic and has been derived from the underlying continental crust, where its generation is associated with the production of radiogenic heat with the approximate relationship 10^{12} atom ^{4}He J^{-1} (ref. 19). The production of heat within the crust of the GHP is estimated to be 25 mW m^{-2} (±50%), which is within the range for average continental crust and corresponds to an equivalent flux of 2.5×10^{10} atom ^{4}He $m^{-2} s^{-1}$. We compare this with the value of $\sim 8 \times 10^{10}$ atom ^{4}He $m^{-2} s^{-1}$ derived by dividing the total crustal helium flux by the area of the basin. Given the uncertainties associated with both values we do not regard them to be significantly different and, considering the persistence of relatively high sub-surface temperatures in Hungary[20] since the late Tertiary, it would be surprising if surface helium loss departed very greatly from the production rate. If further work were to substantiate the difference, however, it would be necessary to consider possible addition of stored 'fossil' ^{4}He from the deeper aquifer systems.

We now consider the broader relationship between heat and helium in the Pannonian Basin, particularly in the light of the studies made on high-temperature hydrothermal vents on mid-ocean ridges[15]. No systematic relationship was found between water temperature and either isotopic composition or concentration of helium and it would perhaps be suprising if such a relationship existed. The aquifer system is known to have an important effect of surface heat flow in the Pannonian Basin[2,20] but primarily by redistributing heat in the upper one or two kilometres of the crust, depressing temperatures in down-flow areas and elevating them where flows ascend. The major contributions to surface heat flow, including crustal radiogenic and sub-crustal sources, originate below the circulation depth. The circulations seem to be principally driven by hydrological head with only minor perturbations by convective thermal instabilities. By contrast, quite different factors control the helium inventory and its isotopic composition: in the case of the crustally derived radiogenic component, it is the age of the waters and to some extent variations in crustal chemistry; in the case of the mantle component, it is probably the distribution of faults and joints that localize the ascent of volatiles from below.

The rates of magmatic addition to the crust discussed earlier are sufficiently low that if they were more or less uniform across the basin, they would make an addition to the crustal heat flow that was undetectable against the major contributions from crustal radioactivity and conduction through the base of the lithosphere; together the latter sustain an average surface heat flow of $\sim$80 mW m^{-2} in the Pannonian Basin[19] whereas magmatic addition at a rate of 20 m Myr^{-1} would contribute only 2 mW m^{-2}. It also follows that the processes transporting helium released by the magma through the crust are unlikely to make a significant contribution to the transport of heat; although hard to substantiate, it is likely that the helium is transported by carbon-dioxide-rich fluids that are of insufficient mass to affect the temperature in the regions through which they pass. □

dependent fractionation (ref. 16; M.R.P. and D. London, unpublished results). Little or no isotope fractionation takes place during hydrothermal leaching of boron from solid reservoirs[18,19].

Tourmaline-rich rocks are present in the Thackaringa, Broken Hill and Sundown Groups, but are most abundant in the upper part of the Broken Hill Group[20,21]. Concentrations of tourmaline are known in pelitic and psammitic metasedimentary rocks, in stratabound and stratiform tourmalinites, in lead-zinc-silver lodes, in stratabound tungsten deposits, in metamorphic segregations and veins, and in granitic pegmatites. Tourmaline separates from these diverse occurrences in the Broken Hill block all have very low $\delta^{11}\mathrm{B}$ values of −23.1 to −17.2‰ (Fig. 3). These values are unique relative to tourmalines from all other massive sulphide deposits and tourmalinites analysed to date[16], except for one tourmalinite from the Archaean Isua Group in West Greenland ($\delta^{11}\mathrm{B} = -22$‰, ref. 22).

We propose that the low $\delta^{11}\mathrm{B}$ values for the Broken Hill tourmalines reflect derivation of boron from source(s) containing isotopically light boron. The only natural reservoirs (Fig. 3) known to have sufficiently low $\delta^{11}\mathrm{B}$ values are borate minerals within non-marine evaporite sequences[23]. Geological data from the Broken Hill block are consistent with this interpretation, including the occurrence of stratiform albitites[24] in the Himalaya Formation (Fig. 2) which are considered to be the metamorphosed equivalents of analcime-rich tuffs or sediments altered in an alkaline sodic environment[3,25] and the presence of the Ettlewood Calc-Silicate Member at the base of the Broken Hill Group which is interpreted as a metamorphosed dolomite-chert unit[3,26]. Further evidence for evaporites includes the occurrence of scapolite locally in the Redan Gneiss and Ettlewood Calc-Silicate Member[3]. Abundant magnetite disseminated in quartzofeldspathic rocks of the Thackaringa Group[24] suggests protoliths of oxidized red beds; local magnetite-sillimanite rocks imply the former existence of bauxites or laterites[3]. Also, N. Herriman (personal communication) has recognized apparent crystal casts of the evaporite minerals kainite and gypsum in relatively undeformed rocks from the Black Prince mine (Fig. 1), which locally contain well preserved sedimentary structures[14,27]; the crystal casts may represent relict diagenetic minerals formed from a hypersaline interstitial brine.

Alternative interpretations of the Broken Hill tourmaline data include: (1) derivation of boron from low-$\delta^{11}\mathrm{B}$ Proterozoic sea water; (2) increased isotope fractionation during low-temperature deposition or diagenesis; (3) metamorphic fractionation. The first possibility is unlikely because tourmalines from other massive sulphide deposits of similar (1,750 ± 50 Myr) age, such as those in the Baltic Shield of Finland and Sweden, hav much higher $\delta^{11}\mathrm{B}$ values[16] (−12.3 to −2.0‰). Because hydrothermal fluids readily leach boron from sediments, and becaus most sediments have high concentrations of boron relative to sea water, the $\delta^{11}\mathrm{B}$ value of the fluid—and thus of precipitated tourmalines—is dominated by the $\delta^{11}\mathrm{B}$ value of the sediment

Low-temperature (<200 °C) formation of tourmaline could produce greater isotope fractionation between fluids and tourmaline and yield low $\delta^{11}\mathrm{B}$ values[16]. This possibility canno be completely excluded for Broken Hill, but there are several arguments against it. First, other stratabound lead-zinc deposits presumed to have formed at low temperatures such as those at Montauban (Quebec) and Balmat (New York) have associated tourmalines with much higher $\delta^{11}\mathrm{B}$ values of +1.6 and +6.7‰, respectively; tourmaline from the geologically similar Broken Hill lead-zinc-silver deposit in the Cape Province of South Africa is also isotopically heavier[16] (−13.8‰). Second, no relationship exists between the $\delta^{11}\mathrm{B}$ values of the Broken Hill tourmalines and their mineralogical, lithological or stratigraphic settings that might reflect different formation temperatures. Tourmalinites in the Globe mine section intimately associated with stratiform lead-zinc-silver lodes and manganese-garnet quartzites contain tourmaline with nearly identical $\delta^{11}\mathrm{B}$ values (−22.5 to −20.9‰) to those from tourmalinites associated with amphibolite and stratabound scheelite mineralization in the Corruga and Yanco Glen areas (−22.8 to −21.9‰). These data from the Broken Hill Group are similar to those for the Thackaringa Group, such as at Stirling Vale where tourmalinites occur locally in bedded albitites ($\delta^{11}\mathrm{B} = -19.7$‰). The similarity in $\delta^{11}\mathrm{B}$ values of tourmalines from these very different environments (and in others throughout the Broken Hill block) is evidence for a common source of the boron or a common process by which they acquired their distinctive $\delta^{11}\mathrm{B}$ values.

Metamorphic recrystallization of tourmaline could produce low $\delta^{11}\mathrm{B}$ values by preferential fractionation of the heavy boron isotope, $^{11}\mathrm{B}$, into a fluid phase or into other aluminosilicate minerals. There is, however, no correlation between tourmaline $\delta^{11}\mathrm{B}$ values and metamorphic grade in the region or with variations in mineral textures or mineral assemblages. Data for coarse-grained (>1 cm), metamorphically recrystallized tourmalines from the Silver King West mine ($\delta^{11}\mathrm{B} = -21.3$‰) and the Jersey Lily mine (−17.2‰) span a similar range of isotopic composition to that determined for fine-grained (<1 mm) tourmalines which apparently are not recrystallized. The relatively high value for the Jersey Lily sample may represent uptake of isotopically heavy boron released from the recrystalliz-

FIG. 2 Generalized lithostratigraphic sequence of the Broken Hill block after Willis *et al.*[2] and Barnes[9]. Total thickness of the sequence is ~7–9 km (refs 2, 3). Stratigraphic locations of important tourmalinites are schematically shown ('t'), based on work of Barnes[8,9,27], Willis *et al.*[2], and Stevens and Slack (unpublished results). Minor occurrences of tourmaline-rich veins, metamorphic segregations and pegmatites are not shown. The Himalaya Formation comprises upper part of the Thackaringa Group.

Boron isotope evidence for the involvement of non-marine evaporites in the origin of the Broken Hill ore deposits

IDENTIFYING the palaeogeographic setting and mode of origin of stratabound ore deposits can be difficult in high-grade metamorphic terranes, where the effects of metamorphism may obscure the nature of the protoliths. Here we report boron isotope data for tourmalines from the early Proterozoic Broken Hill block, in Australia, which hosts giant lead–zinc–silver sulphide deposits. With one exception the $^{11}B/^{10}B$ ratios are lower than those for all other tourmalines from massive sulphide deposits and tourmalinites elsewhere in the world. We propose that these low ratios reflect leaching of boron from non-marine evaporitic borates by convecting hydrothermal fluids associated with early Proterozoic continental rifting. A possible modern analogue is the Salton Sea geothermal field in California.

The Broken Hill block is an inlier of early Proterozoic metamorphic and igneous rocks in western New South Wales, Australia (Fig. 1). Proterozoic rocks there consist of metasedimentary schists and gneisses and minor metavolcanic rocks[1-3] that have undergone complex post-depositional deformation and regional metamorphism[4-6], including granulite-facies pressure and temperature conditions developed in the southern part of the block[5]. The palaeotectonic setting of the region is generally considered to represent an intracontinental rift[2,3].

Detailed mapping studies[1-3] have recognized a coherent stratigraphy in the Broken Hill block (Fig. 2). The lowest stratigraphic units (Thackaringa Group and below) have recently been re-interpreted[3,7] as fluvio-deltaic and lacustrine (or coastal sabkha) sequences, overlain by shallow marine sands and shales comprising the Broken Hill, Sundown and Paragon Groups; tholeiitic basalt flows, tuffs or sills (presently amphibolites) and possible rhydodacitic volcanics (now quartzo-feldspathic gneisses) are mainly within the Thackaringa and Broken Hill Groups. A variety of stratabound and stratiform mineralization occurs in these same two groups[8,9] including the giant lead-zinc-silver lodes[10,11] stratigraphically within the upper part of the Broken Hill Group.

The borosilicate tourmaline is an accessory gangue mineral in many massive sulphide deposits, particularly those in dominantly clastic metasedimentary terranes[12,13]. Tourmaline is also the diagnostic mineral in stratabound tourmaline-rich rocks or tourmalinites, which are associated with a variety of stratabound (and commonly stratiform) mineral deposits[12,14,15]. Like massive sulphide deposits, most tourmalinites are believed to form by syngenetic or diagenetic processes before regional metamorphism[12-15]. Palmer and Slack[16] recently determined the boron isotopic composition of tourmaline in over 40 stratabound massive sulphide deposits and tourmalinites from diverse geological and tectonic settings worldwide. Figure 3 shows the range of $\delta^{11}B$ values obtained for tourmaline separates from these stratabound deposits ($n = 52$) and for Broken Hill ($n = 34$), together with the ranges observed for various fluid and solid boron reservoirs (the analytical details are given in ref. 16). The major control over the $\delta^{11}B$ values of the tourmalines is the composition of the boron source, especially the nature of footwall lithologies; secondary controls are water/rock ratios (indicated by $\delta^{18}O$-$\delta^{11}B$ relationships) and seawater entrainment (indicated by local geological settings)[16]. Tourmalines from dominantly clastic metasedimentary and metavolcanic terranes have intermediate $\delta^{11}B$ values (−15.7 to −1.5‰), whereas tourmalines from marine metaevaporite and carbonate-associated terranes have higher $\delta^{11}B$ values (typically >0‰). In both groups, tourmaline $\delta^{11}B$ values are systematically lower than that of the fluid from which they precipitated and that of the solid reservoirs from which the boron was originally derived. Boron isotope systematics are such that the light isotope, ^{10}B, is preferentially partitioned into the solid phase during fluid-solid interactions[16,17]. Under the pressure and temperature conditions inferred for massive sulphide and tourmalinite formation, tourmalines are interpreted to be 5-12‰ lighter than the boron-bearing fluid phase, mainly as a function of temperature-

§ Present Address: Department of Geology, Wills Memorial Building, Queen's Road, University of Bristol, Bristol BS8 1RJ, UK.

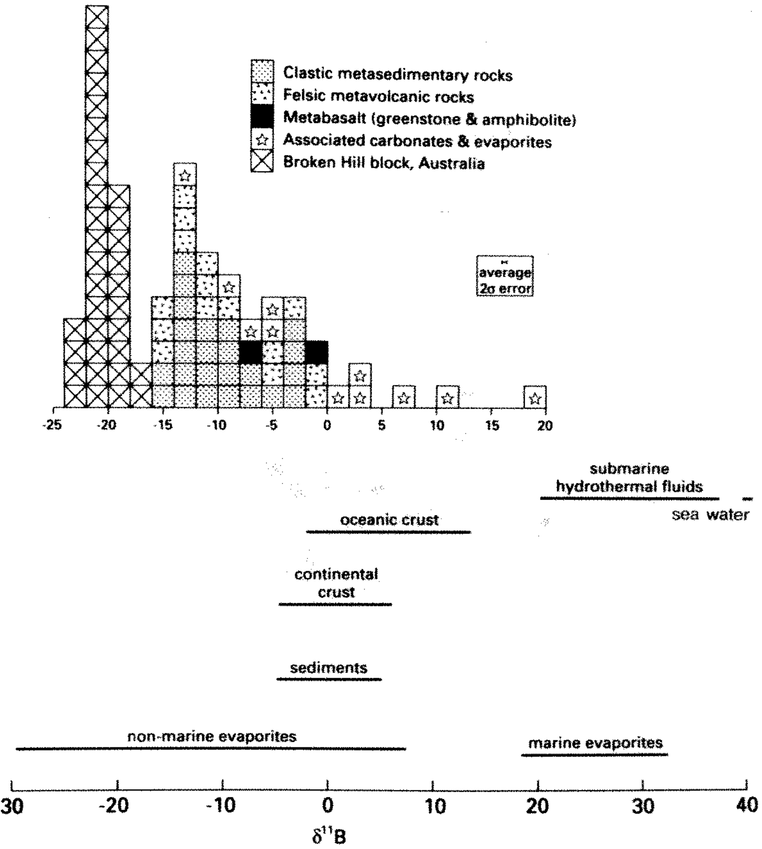

FIG. 3 Boron isotopic compositions of tourmaline (above) from the Broken Hill block compared with those from massive sulphide deposits and tourmalinites in geological settings elsewhere[16]. Lower scale shows the range of boron isotopic compositions identified for various fluid and solid boron reservoirs in nature[18,19,23]. $\delta^{11}B = [(^{11}B/^{10}B)_{sample}/(^{11}B/^{10}B)_{standard}] - 1$, where the standard is NBS boric acid SRM 951.

ation of local boron-bearing silicates (such as sillimanite[28]), but it clearly does not indicate significant boron loss during prograde metamorphism. The retrograde metamorphism[6,29] common in parts of the Broken Hill block (Fig. 1) also has not substantially affected the boron isotopic composition of the tourmalines, as indicated by $\delta^{11}B$ values of −21.4‰ for metamorphically corroded tourmaline from a retrograde shear zone near the Nine Mile mine, and −20.1‰ for unaltered tourmaline from the same area but outside the shear zone. The −1.3‰ shift in $\delta^{11}B$ for this corroded tourmaline is in agreement with predicted isotope behaviour at high temperatures (M.R.P. and D. London, unpublished results), but is not significant relative to the range of $\delta^{11}B$ values measured for Broken Hill. We conclude that the mechanical and chemical stability of tourmaline, together with the lack of other boron-rich mineral hosts in the district, prevented major boron isotope fractionation during metamorphism in the Broken Hill block. This interpretation is consistent with tourmaline $\delta^{11}B$ data from greenschist-, amphibolite-, and granulite-facies terranes elsewhere[16].

Our model, based on boron isotope and other data, suggests that parts of the Thackaringa Group originally contained non-marine evaporites. Borates within such evaporites provide a source of abundant, readily extractable boron; concentrations of saline minerals and carbonates are also likely to have been present in such a setting. Deposition of the overlying Broken Hill Group in a shallow marine basin[3,7] was apparently associated with continental rifting and the development of a convecting hydrothermal system that extended into the underlying sediments of the Thackaringa Group, leaching them of boron, salts and, perhaps, sulphur and metals. The major stratabound lead-zinc-silver ores were then deposited by exhalative and/or diagenetic replacement processes together with siliceous lode rocks and manganese-iron sediments (such as garnet quartzites); coeval tourmalinites and stratabound tungsten mineralization formed generally in distal sedimentary environments. Widespread tourmalinites in the Broken Hill block, and the abundance of carbonate gangue in the main lead-zinc-silver lodes, may be explained by a source reservoir of non-marine evaporitic borates and carbonates in the Thackaringa Group. We suggest that the restriction of abundant carbonate to the lode horizons[9-11] in the upper Broken Hill Group reflects boiling of carbon-dioxide-rich hydrothermal fluids in a shallow marine basin, in which the carbon dioxide was derived by leaching of carbonate-bearing evaporites in the underlying Thackaringa Group. Evaporite salts in the Thackaringa Group leached by convecting hydrothermal fluids and resultant increased metal-chloride complexing may have been critically important for transporting the huge quantities of lead, zinc and silver deposited in the main lodes.

A possible modern analogue of the Broken Hill block is the Salton Sea geothermal field in southern California where deep geothermal fluids that interact with Pliocene lacustrine and non-marine evaporite sequences[30,31] have high concentrations of sodium, calcium, potassium, iron, manganese, zinc, lead, chlorine, lithium and boron[32]. This geothermal system is actively depositing iron-zinc-lead-copper sulphide minerals with $\delta^{34}S$ values from −9 to +9‰ (similar to sulphides of the Broken Hill lode[33,34]) which reflect sulphur derivation by the hydrothermal reduction of anhydrite-derived sulphate in evaporitic sediments at depth[35]. Continued rifting of the Salton Trough and transgression by sea water from the Gulf of California could produce a geological setting similar to that postulated for Broken Hill and an environment favourable for the formation of stratabound lead-zinc-silver mineralization and related tourmalinites. □

Wavelength sensitivity in blindsight

Petra Stoerig* & Alan Cowey†

* Institute of Medical Psychology, Ludwig-Maximilians-University, Goethestrasse 31, 8 Munich 2, West Germany
† Department of Experimental Psychology, Oxford University, South Parks Road, Oxford OX1 3UD, UK

BLINDSIGHT—the residual visual functions observed in visual-field defects resulting from destruction of part of the primary visual cortex (striate cortex) even though visual stimuli presented in the field defect are not consciously perceived—has generated new insights into the nature of consciousness and the role of the extrastriate pathways in visual processing. Some patients can detect and localize unseen stimuli when they are required to guess[1–4]. Discrimination of movement[5,6], flicker[5,7] and orientation[4,8] may also be present, but residual colour discrimination is controversial. Negative results (see ref. 9 for review) imply that only the pathways from eye to striate cortex can transmit information about colour in primates. By measuring sensitivity to light of different wavelengths in patients with blindsight we show that spectral sensitivity in the blind fields is surprisingly high, with a reduction of only 1 log unit or less across the visible spectrum. It is also essentially normal in form, whether the patients are adapted to light or dark. The shift in peak sensitivity from medium to shorter wavelengths in adaptation to the dark (the Purkinje shift) and the presence of discontinuities in the light-adapted curve together show that blindsight involves both rod and cone contributions, and that some colour opponency remains. As colour opponency requires input from primate beta retinal ganglion cells, two-thirds of which degenerate transneurally after a striate cortical lesion in juvenile monkeys[10], our results show that the surviving subpopulation of primate beta cells is functional.

The investigation of blindsight provides the only available behavioural method of isolating and studying the properties of the extra-geniculostriate cortical visual pathways in man, and can show which aspects of visual coding require the striate cortex and which do not. Damage to the striate cortex eventually leads to the death of the majority of ganglion cells in the corresponding part of the retina in man[11], and also in monkeys, where the degeneration is selective for, and involves up to 80% of, the colour opponent primate beta ($P\beta$) cells[10]. To see whether the pathways from the degenerated hemiretina can process wavelength information we measured spectral sensitivity in the normal and blind fields of three patients in whom blindsight had been previously demonstrated[9], and in two normal observers. We used both adaptation to the light and dark because the contradictory reports on colour discrimination in blindsight[4,5,7,9,12–16] include a demonstration that spectral sensitivity of totally destriated monkeys is characteristic of rod receptors regardless of adaptation level[15], indicating that only the colour-blind rod channel is effective.

The subjects were tested in a Tübinger perimeter, using monocular viewing such that their field defect was on the temporal side, corresponding to the normally more sensitive nasal retina. The field defects of the three patients are shown in Fig. 1. Stimuli were presented at positions 10° eccentric from the fixation axis, permitting a comparison of sensitivity at mirror-symmetric positions in the hemifields. While held by a head and chin rest, the subject fixated a central dim red point. The viewing eye was monitored through an infrared video system. Nine coloured targets (116′, 200 ms) from 450 to 660 nm were used. Each was produced by a narrowband, 9–13 nm, interference filter. In the normal visual hemifield detection thresholds were repeatedly measured by progressively increasing stimulus intensity by 0.05 log units until the subject reported seeing the target on three consecutive presentations. For the blind field a guessing paradigm was used. Blank trials (on which no target

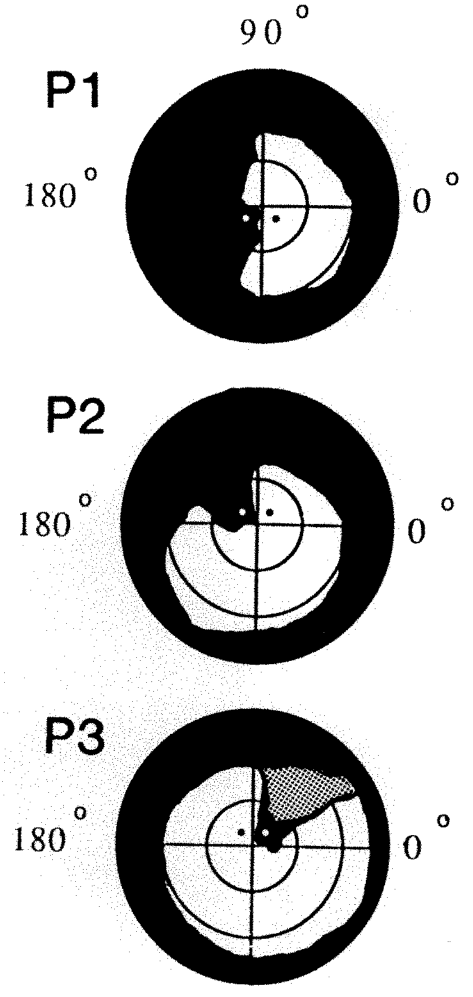

FIG. 1 Visual fields of patients plotted by moving a 320 cdm^{-2} 44′ white target on a 10 cdm^{-2} background from the periphery towards the fixation point. The stippled area in P3 was amblyopic, as revealed by stationary flashed targets. Black or white spots at 10° eccentricity indicate the position where coloured targets were presented in intact or blind fields respectively.

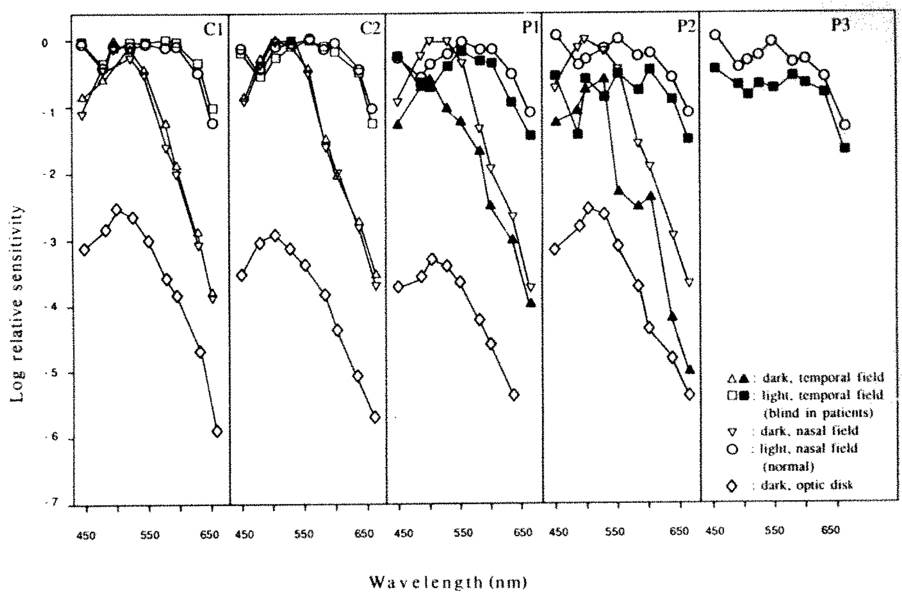

FIG. 2 Relative spectral sensitivity at an eccentricity of 10° in two normal subjects and in the patients whose field defects are shown in Fig. 1. In each graph the most sensitive dark-adapted value is scaled to zero. The light-adapted values have been raised by 4.3(C1), 3.9(C2) and 3.7(P1,P2) log units so that the envelopes of the light- and dark-adapted curves can be readily compared. The key to the symbols is below the curves for P3, who was not tested when dark adapted. Black symbols refer to blind fields.

was presented) and stimulus trials, with an overall ratio of 4:1, were presented randomly, and the patient was asked to guess whether a light had been presented. After each batch of up to 250 trials, target luminance was increased by 0.1 long units, until detection was statistically significant at the 5% level. If a different value was obtained when the measurement was repeated, the mean was used. Stimuli were presented on a white 3,500 ± 1,000 K background of low photopic (32 $\mathrm{cd\,m^{-2}}$) or scotopic luminance (0.0001 $\mathrm{cd\,m^{-2}}$) after 20 min of adaptation to the dark. Under scotopic conditions, straylight detection thresholds were determined by presenting the targets in the natural blind spots; under photopic conditions the targets could not be made intense enough to be detectable in the blind spot.

Figure 2 shows the spectral sensitivity curves. Note that sensitivity in the normal and blind fields has a single peak at 500 nm under adaptation to the dark, the smooth curve and steep decline above 550 nm being characteristic of rod vision. Sensitivity in the blind fields is normal, apart from being reduced by up to a long unit, and the curves are less smooth. Comparison with the straylight detection thresholds measured under adaptation to the dark for targets on the reflective natural blind spot, which are 2-3 log units higher than for nearby targets in normal retina, shows that as sensitivity in the blind field is reduced by not more than 1 log unit it is not based on the detection of light scattered onto the functionally normal retina. Under adaptation to the light there is no steep decline in sensitivity above 550 nm such as occurs under scotopic conditions; instead, the curve shifts towards the longer wavelengths, showing that cones are involved.

Whereas the sensitivity of the colour-opponent system, especially when tested with targets on a high photopic white surround, has peaks at about 450, 525–550, and 600 nm, and notches at 480 and 580 nm (refs 17–19) (their precise positions depending on intensity and colour temperature of the background) the luminance system has a single broad peak around 555 nm (ref. 19). Given that the more sensitive system will determine threshold, we assume some contribution of the luminance system in governing sensitivity around 550 nm that is in accordance with the lack of a clear notch at 580 nm in several photopic curves. The sensitivity of the luminance system, however, decreases smoothly towards the short wavelengths[19], probably because the broadband channels receive little if any input from short wavelength ('blue') cones[20,21], and can therefore not be responsible for the prominent secondary increase in sensitivity from 480/500 nm to 450 nm. The presence of this increase in all photopic curves indicates that colour opponent processes contribute to or even determine thresholds for the 450 nm blue stimulus. This is supported by the results of colour naming at threshold in the good field, which was faultless for the blue and red, but uncertain and occasionally wrong for green and yellow stimuli.

Together, our results show that spectral sensitivity as measured under the present conditions differs between normal and cortically blind hemifields only in terms of absolute sensitivity. This difference is fairly small and is not an artefact of comparing different detection methods because it was not altered when the same guessing paradigm was applied in the normal field. There is no evidence that sensitivity is mediated solely by rod receptors, as this would abolish the marked difference between curves measured under adaptation to the light and dark. All measurements made under photopic conditions show contributions from cone receptors. The notch or shoulder at 580 nm and the rise in sensitivity from 480 to 450 nm provide evidence for colour opponent processes. If chromatic opponency does remain in blindsight, genuine wavelength discrimination may also be possible. This can now be tested by presenting coloured stimuli that are matched for luminous efficiency on the basis of the patient's own spectral sensitivity. Thus far, evidence indicates that the subpopulation of surviving $P\beta$ ganglion cells, which are the only known ganglion cells to provide colour-opponent signals, is still functional. As chromatic opponency has never been detected in the midbrain visual pathway (a favourite candidate for the mediation of blindsight) remaining retinal projections to the thalamus and from there to extrastriate cortex may be involved[22,23]. □

Arachidonic acid induces a prolonged inhibition of glutamate uptake into glial cells

Boris Barbour, Marek Szatkowski, Nick Ingledew & David Attwell

Department of Physiology, University College London, Gower Street, London WC1E 6BT, UK

ACTIVATION of NMDA (*N*-methyl-D-aspartate) receptors by neurotransmitter glutamate stimulates phospholipase A_2 to release arachidonic acid[1,2]. This second messenger facilitates long-term potentiation of glutamatergic synapses in the hippocampus[3], possibly by blocking glutamate uptake[4,5]. We have studied the effect of arachidonic acid on glutamate uptake into glial cells using the whole-cell patch-clamp technique to monitor the uptake electrically[6,7]. Micromolar levels of arachidonic acid inhibit glutamate uptake, mainly by reducing the maximum uptake rate with only small effects on the affinity for external glutamate and sodium. On removal of arachidonic acid a rapid (5 minutes) phase of partial recovery is followed by a maintained suppression of uptake lasting at least 20 minutes. Surprisingly, the action of arachidonic acid is unaffected by cyclo-oxygenase or lipoxygenase inhibitors suggesting that it inhibits uptake directly, possibly by increasing membrane fluidity. As blockade of phospholipase A_2 prevents the induction of long-term potentiation (LTP)[8], inhibition of glutamate uptake by arachidonic acid may contribute to the increase of synaptic gain that occurs in LTP. During anoxia, release of arachidonic acid[9] could severely compromise glutamate uptake and thus contribute to neuronal death.

Application of L-glutamate to glial (Müller) cells from the salamander retina evokes an inward current reflecting glutamate uptake by an electrogenic carrier that transports Na^+ into the cell[6,7]. A response with similar characteristics has recently been demonstrated in mammalian glial cells[10,11]; we used salamander glia for this study because of the large uptake current they exhibit. Glutamate uptake was monitored as the inward current evoked by 30 μM glutamate in isolated glial cells voltage-clamped to −40 mV. Arachidonic acid produced a slowly developing inhibition of glutamate uptake (Fig. 1*a*–*c*). The uptake current was halved by 2 minutes' exposure to 10 μM arachidonic acid, and significant inhibition was seen with 1 μM arachidonic acid (Fig. 1*d*).

The dependence of the uptake current on external glutamate and external sodium concentrations, measured before and after applying arachidonic acid, showed that arachidonic acid suppresses uptake largely by reducing the maximum uptake rate, with a small increase in the apparent affinity for glutamate and a small decrease in the apparent affinity for external sodium (Fig. 2*a*, *b*).

The mechanism of action of arachidonic acid was investigated pharmacologically. Ouabain (10^{-4} M) did not prevent the inhibition produced by arachidonic acid (Fig. 3*a*), which was therefore not an indirect result of intracellular Na^+ accumulation following inhibition of the sodium pump by arachidonic acid[4]. The cyclo-oxygenase inhibitor indomethacin (5 μM) had no effect on the uptake inhibition (Fig. 3*b*), ruling out the possibility that it depends on the conversion of arachidonic acid to prostaglandin derivatives. Nordihydroguaiaretic acid (NDGA, 10 μM), a lipoxygenase inhibitor, produced a slowly developing inhibition of uptake similar to that seen with arachidonic acid (possibly by inhibiting breakdown of arachidonic acid produced by the glial cell itself), but did not prevent inhibition of uptake by arachidonic acid (Fig. 3*c*). Metabolites of arachidonic acid like HPETE[12] are therefore not responsible for the inhibition of

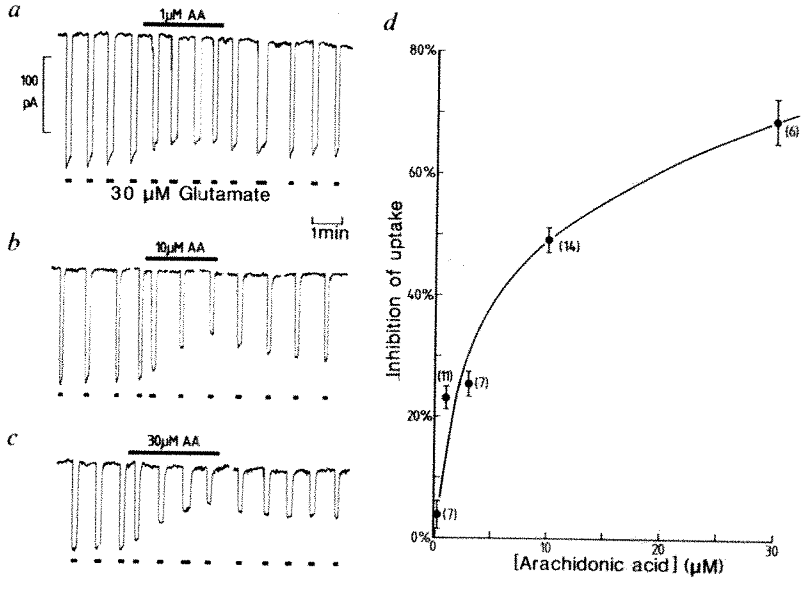

FIG. 1 Arachidonic acid inhibits glial cell glutamate uptake. *a*, *b* and *c*, current changes in three different Müller cells voltage-clamped to −40 mV during repeated application of glutamate (30 μM) (timing shown by black bars below each record). Glutamate evokes an inward current (downward deflection) reflecting electrogenic glutamate uptake[6]. Application of 1 μM (*a*), 10 μM (*b*) or 30 μM (*c*) arachidonic acid produces a slowly developing inhibition of the glutamate-evoked current. *d*, Percentage suppression of glutamate uptake (mean ± s.e.) as a function of arachidonic acid concentration measured after 2 min in the presence of arachidonic acid (number of cells shown by each point; smooth curve drawn by eye). During prolonged recordings even in the absence of arachidonic acid there is a slow decay of glutamate-evoked current, typically 2% per min, which correlates with a decrease in cell capacitance (measured from the current response to voltage jumps). To compensate for this loss of cell area, which would otherwise lead to an overestimate of the suppressive effect of arachidonic acid, glutamate-evoked currents were normalized by the cell capacitance measured before and in the presence of arachidonic acid. Normalized uptake current declined much more slowly over a prolonged recording period than did the un-normalized current (see Fig. 4).

METHODS. Glial (Müller) cells isolated from the tiger salamander retina[6] were whole-cell clamped using pipettes containing (mM): KCl, 95; HEPES, 5; NaCl, 5; Na_2ATP, 5; $MgCl_2$, 7; $CaCl_2$, 1; K_2EGTA, 5; the pH was adjusted to 7.0 with 14 mM KOH. External solution contained (mM): NaCl, 105; KCl, 2.5; $CaCl_2$, 3; $MgCl_2$, 0.5; glucose, 15; HEPES, 5; $BaCl_2$ (to block the cells' potassium conductance), 6. The pH was adjusted to 7.3 with 2 mM NaOH. Temperature, 20–23 °C. Arachidonic acid (Sigma) was stored under nitrogen at −20 °C as a 10 mM stock suspension in water or occasionally in DMSO, which gave similar results. When required this stock was thawed, sonicated for 5 min, and added to the superfusion solution, which was then sonicated for 5 min.

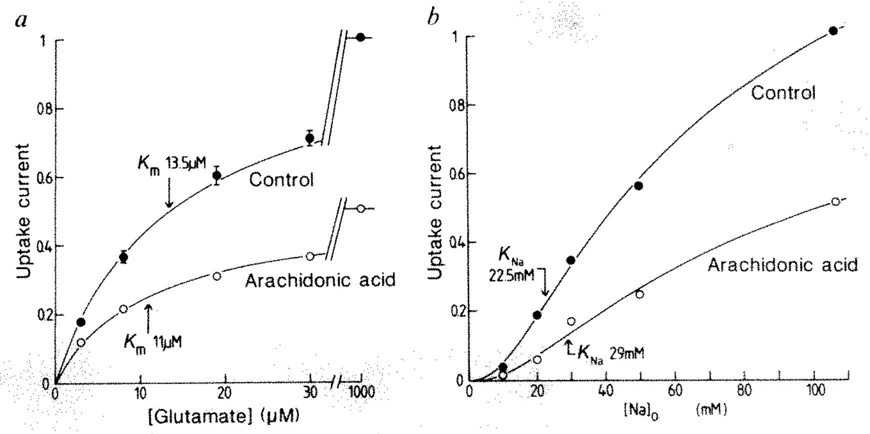

FIG. 2 Effect of arachidonic acid on the glutamate- and sodium-dependence of glutamate uptake. *a*, Dependence of uptake current (at −40 mV) on glutamate concentration before (●) and after (○) 3 min in the presence of 10 μM arachidonic acid. All data normalized to the saturating response before arachidonic acid. Mean (±s.e.) data from 10, 11, 5 and 6 cells for 3, 8, 19 and 30 μM glutamate. Curves through the points are Michaelis–Menten relations with $K_m = 13.5$ μM, $V_{max} = 1$ before, and $K_m = 11$ μM, $V_{max} = 0.5$ after arachidonic acid. Arachidonic acid halves the V_{max} of uptake with a small increase in apparent glutamate affinity. *b*, External sodium-dependence of the uptake current (at −40 mV) evoked by 30 μM glutamate before (●) and after (○) 3 min in 10 μM arachidonic acid. Data normalized to control response in 107 mM $[Na]_o$. Mean data (s.e.< symbol size) from 3, 5, 11 and 5 cells in 10, 20, 30 and 50 mM $[Na]_o$. Smooth curves are empirical fits with the form: $V_{high\,Na}\{[Na]_o/([Na]_o + K_{Na})\}^3$, with $K_{Na} = 22.5$ mM, $V_{high\,Na} = 1.77$ before, and $K_{Na} = 29$ mM, $V_{high\,Na} = 1.05$ after arachidonic acid. On this basis, most of the uptake inhibition produced by arachidonic acid in 107 mM $[Na]_o$ in Fig. 1 results from a decrease in the rate of uptake that would be observed in saturating $[Na]_o$, although there is some contribution from the decrease in apparent affinity for Na_o. Fitting the data with the Hill equation instead of a power of the Michaelis–Menten relation led to the same conclusion.

glutamate uptake. Oleic acid inhibited uptake approximately half as well as arachidonic acid (Fig. 3*d*). Phorbol ester, which stimulates protein kinase C by 20–60%[13], had little effect on uptake (Fig. 3*e*), ruling out the possibility that arachidonic and oleic acids reduce uptake by stimulating this kinase[13]. The longer *cis*-unsaturated fatty acid docosahexaenoic acid, which has no effect on protein kinase C[13], produced an inhibition of uptake similar to that produced by arachidonic acid, and the protein kinase inhibitor H-7 had no effect on the action of arachidonic acid (see Fig. 3*e* legend).

To test whether the effects of arachidonic and oleic acids are a consequence of the lipid disruption produced by the kinked *cis* double bonds in their structures (20:4 and 18:1 respectively), we applied two linear analogues of these molecules. Elaidic acid (18:1), a homologue of oleic acid with a *trans* instead of a *cis* double bond, produced only one quarter of the uptake inhibition produced by oleic acid (Fig. 3*f*). Similarly arachidic acid (20:0), the saturated analogue of arachidonic acid, produced only about one fifth of the inhibition that arachidonic acid did (Fig. 3*g*).

These results are consistent with the inhibition of uptake produced by arachidonic acid being due to the disruption of membrane lipid organization (increase in membrane fluidity) caused by the introduction of unsaturated fatty acid into the membrane. The messenger actions of arachidonic acid are usually attributed to its lipoxygenase and cyclo-oxygenase derivatives. The direct action of arachidonic acid we propose here is similar to that suggested for the effect of arachidonic acid on the sodium pump[14]. Changes of membrane fluidity have also been proposed to regulate phosphate and glucose uptake in the kidney[15].

The kinetics of action of arachidonic acid are of interest with respect to the possible role of arachidonic acid in long-term

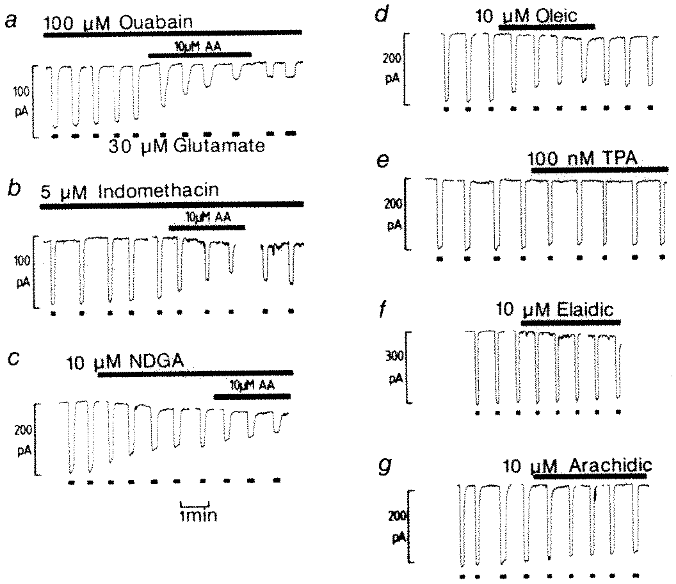

FIG. 3 Pharmacology of the uptake inhibition. Uptake measured as the current (normalized by capacitance for quantitative analysis, see Fig. 1) evoked at −40 mV by 30 μM glutamate. *a*, Ouabain does not prevent the uptake inhibition produced by 10 μM arachidonic acid. Mean (±s.e.) inhibition produced in three cells by 2 minutes' arachidonic acid in the presence of 10^{-4} M ouabain was 55.6 ± 2.7%, similar to that seen without ouabain (Fig. 1). *In vivo*, where Na_i is not controlled by the patch pipette, accumulation of Na^+ inside the cell, following inhibition of the sodium pump[4] by arachidonic acid, may contribute to inhibition of glutamate uptake. *b*, Indomethacin (5 μM, for 25 min) does not prevent the uptake inhibition produced by 10 μM arachidonic acid. Mean inhibition produced by 2 minutes' arachidonic acid after 20–30 min in indomethacin was 47.9 ± 5.3% ($n = 3$), similar to that without indomethacin. In toad bladder, 6 μM indomethacin inhibits cyclo-oxygenase by >90%[21]. *c*, Nordihydroguaiaretic acid (NDGA, 10 μM) does not prevent the uptake inhibition produced by 10 μM arachidonic acid. NDGA itself reduced the uptake current (by 52.8 ± 2.1% after 8 min in NDGA, $n = 9$), and subsequent application of arachidonic acid further reduced uptake by 45.1 ± 4.7% ($n = 10$, after 2 min), similar to the inhibition seen without NDGA. Estimates of the 50% inhibitory concentration for NDGA block of lipoxygenase in rat and human are ~0.9 μM and ~3 μM, respectively[22,23]. *d*, Oleic acid, with one *cis* double bond in its structure, unlike the four in arachidonic acid, reduces uptake, but to a lesser degree than arachidonic acid. Mean reduction produced by 2 min of 10 μM oleic acid was 28.9 ± 1.0% (seven cells). *e*, Arachidonic and oleic acids do not act by stimulating protein kinase C. Phorbol 12-myristate 13-acetate (TPA, 100 nM), which activates protein kinase C by 20–60%[13], has little effect on uptake (mean reduction in five cells after 4.5 min in TPA was 5.5 ± 0.9%). Similar results were obtained with 10^{-6} M pipette $[Ca^{2+}]$, rather than 10^{-7} M $[Ca^{2+}]_{pipette}$ as here. Furthermore, docosahexaenoic acid (22:6, 10 μM for 2 min), which has no effect on protein kinase C[13], reduced the uptake current by 58.9 ± 2.6% ($n = 5$, data not shown). Including the protein kinase inhibitor H7 (340 μM) in the patch pipette had no effect on the uptake inhibition produced by arachidonic acid in five cells. *f*, Elaidic acid has much less effect on uptake than does its *cis* homologue oleic acid. Mean reduction of uptake after 2 min in 10 μM elaidic acid was 6.7 ± 1.8% (nine cells). *g*, Arachidic acid has much less effect on uptake than does its polyunsaturated analogue arachidonic acid. Mean reduction of uptake after 2 min in 10 μM arachidic acid was 10.4 ± 1.3% (eight cells). Drugs were made up as stock solutions in dimethylsulphoxide (DMSO) (0.1% final concentration; DMSO was also added to control solutions). Gaps in the records are where voltage pulses were applied to measure cell capacitance.

expression, developmental regulation and localization. The complementary DNA-deduced amino-acid sequence and subsequent expression of cDNA clones covering the entire coding region in HeLa-cells indicate that CNTF is a cytosolic protein. This, together with its regional distribution and its developmental expression, show that CNTF is not a target-derived neurotrophic factor. CNTF thus seems to exhibit neurotrophic and differentiation properties only after becoming available either by cellular lesion or by an unknown release mechanism.

CNTF was purified from adult rat sciatic nerve as described previously[5], using an additional HPLC purification step (for details see legend to Table 1). The amino-acid sequences of the various fragments determined by gas-phase microsequencing represented more than 50% of the protein. The peptide sequences thus obtained matched perfectly with those deduced from cDNA cloning as shown in Fig. 1.

To obtain RNA for molecular cloning, we used cultures of rat brain cells that previously had been shown to produce substantial quantities of CNTF (ref. 7). After various polymerase chain reaction steps, the nucleotide sequences of clones A, B, C revealed a short 5′ untranslated region of 77 base pairs (bp) and an open reading frame of 600 bp, predicting a protein 200 amino acids long with a 3′ untranslated region of 436 bp, which ends in a poly(A) tail (Fig. 1*b*). The initiation site for translation was localized at position 78–80 of the nucleotide sequence. A stop codon located 5′ to this initiation site at position 72–74 and G residues in positions 75 and 81 fulfil the requirements for an adequate translation initiation site, according to Kozak[8].

Although the dibasic (Arg–Arg) sequence in positions 13 and 14 of the predicted sequence represents a potential post-translational cleavage site, the amino-acid composition of purified CNTF (Table 1) does not favour such a cleavage: the amino acids phenylalanine, arginine and alanine present in the N-terminal region are not reduced relative to other amino acids that are absent from this region (for example, isoleucine). Moreover, the predicted relative molecular mass (M_r) of 22,800 (22.8K), corresponding to the 200-amino-acid sequence is in complete agreement with that estimated from PAGE analysis (22.5K) (ref. 6). Thus, the amino-acid sequence of CNTF shows the features of a cytosolic protein; that is, no signal peptide, no consensus sequences for glycosylation and only one cysteine residue at position 17. Comparison of the determined CNTF sequence with those of the PIR and EMBL databases did not reveal significant similarities with any other known protein. In

FIG. 1 *a*, Complementary DNA cloning, and *b*, nucleotide and deduced amino-acid sequence of CNTF. The oligonucleotides used as primers are shown in *c* and their corresponding positions in the nucleotide sequence in *b*. Multiple cloning sites are indicated as lower-case letters. In the case of degenerated codons we used IUPAC symbols. Underlined amino acids in *b* correspond to the peptide sequences obtained from tryptic (T1-T8) and cyanogen bromide (CBI-4) fragments of CNTF. At the nucleotide level, sequences corresponding to the coding region are bold-faced and the polyadenylation signal sequence is underlined.

METHODS. Cultured rat astrocytes were grown for 3 weeks as described[20]. One day after final subculturing, total RNA was extracted from the cells[21]. Complementary DNA was synthesized using oligonucleotide 5 and reverse transcriptase of the Moloney murine leukaemia virus (Bethesda Research Laboratories). The first strand of cDNA served as a template for amplification of specific segments of CNTF using PCR[22]. Clone A was generated using the degenerated primer-oligos 1 and 2; the PCR product was identified with oligonucleotide 11, subcloned and sequenced by the dideoxynucleotide chain-termination method[23]. The nucleotide sequence thus obtained was used to synthesize primers 3 and 4 for amplification of cDNA ends according to Frohmann *et al.*[24] The cDNAs obtained were subcloned into the Bluescript SK+ vector (Stratagene) and sequenced (clones B and C). Oligonucleotide 7 was derived from the sequence of a genomic clone (Carroll, unpublished data). This primer, together with oligonucleotide 6 was used to create clone D using essentially the same protocol as for clone C, except that we performed a G-tailing procedure instead of T-tailing to generate 5′clones[25]. The inserts of several clones were sequenced and shown to be identical. PCR with newly synthesized cDNA from astrocytes and oligonucleotides 9 and 10 revealed a cDNA clone covering the entire coding region. The cDNA thus obtained (Fig. 1*a*, clone E) was used for expression in eukaryotic cells.

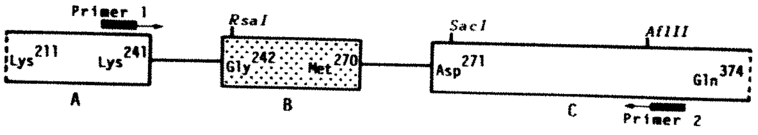
FIG. 1 Schematic representation of the structure of two isoforms of the D_2 dopamine receptor. These two isoforms, termed $D_{2(415)}$ and $D_{2(444)}$, differ in that the latter has a predicted 29-amino-acid sequence located within the putative third cytoplasmic loop between Lys 241 and Asp 242 (nucleotides 723 and 724). Note the presence of two potential glycosylation sites at Asn 243 and Asn 260. Otherwise the nucleotide sequence of the two clones is identical to that established by Bunzow *et al.*[7].

METHODS. Overlapping oligonucleotides were synthesized (Clontech) from the sequence of D_2 dopamine receptor cDNA (nucleotides 146–233 in ref. 7), radiolabelled by 'filling reaction' using *Escherichia coli* DNA polymerase I (Klenow fragment; Boehringer) and used to screen an oligo(dT)-primed cDNA library constructed in λgt10 (refs 20 and 21) from total rat brain poly(A)$^+$ RNA[22,23]. After transfer of the phage onto nitrocellulose filters (BA 85; Schleicher & Schuell), they were hybridized at 42 °C for 16 h in a buffer (6 × SSC, 0.05% sodium pyrophosphate, 8 mM Tris-HCl buffer, pH 7.4, 20% formamide, 1 × Denhardt's solution, 100 μg ml^{-1} yeast transfer RNA and 20 μg ml^{-1} salmon sperm DNA) containing 5×10^5 d.p.m. of the synthetic probe per ml. Filters were washed twice for 20 min at 25 °C in 2 × SSC, 0.05% sodium pyrophosphate, 0.1% SDS and, twice for 30 min at 37 °C in 0.2 × SSC, 0.1% SDS, 0.05% sodium pyrophosphate. *Eco*RI inserts of positive clones were subcloned in M13 mp18 or mp19 vectors (Boehringer) for sequencing[24] and in pGEM-4Z (Promega Biotec) for restriction analysis and preparation of fragments for use as probes.

protein with a total of 444 amino acids: the $D_{2(444)}$ receptor (Fig. 1). The sequences otherwise are 100% homologous in their coding regions and with the cDNA previously described[7].

We analysed rat genomic DNA to confirm that the $D_{2(415)}$ and $D_{2(444)}$ receptors are products of the same gene. First, Southern blot analysis indicated the presence of unique *Bam*HI and *Eco*RI restriction fragments, of 7.5 and 4.5 kilobases (kb) respectively, when probed with the *Sac*I–*Afl*II fragment (Fig. 2), which corresponds to a part of the third cytoplasmic loop common to both $D_{2(415)}$ and $D_{2(444)}$ receptors (data not shown). We also screened a genomic library with a *Bam*HI–*Bgl*II probe containing the full coding sequence of the cDNA for the $D_{2(444)}$ receptor (nucleotides 4 to 1,319), and then selected 21 clones out of 10^6 that were either identical or overlapping, using restriction enzyme digestion and Southern blot analysis. All of these clones hybridized strongly to an *Rsa*I–*Sac*I probe, corresponding mainly to the 29-amino-acid fragment characteristic of the $D_{2(444)}$ receptor (Fig. 2). Partial sequencing of these clones revealed the complex organization of the gene: it is at least 12 kb long and contains a minimum of six introns, including five in the coding region. Four introns are located at nucleotide positions −33, 286, 533 and 1,142 of the cDNA for the $D_{2(415)}$ receptor, the last one of which has been reported[7]. It is noteworthy that the 87-bp sequence characteristic of the $D_{2(444)}$ receptor is flanked by two other introns, indicating that the two isoforms of the D_2 receptor are products of the same gene, generated by alternative mRNA splicing of the 87-bp exon (Fig. 2). Although all other splice donor and acceptor sequences consist of frequently occurring sequences[8], this is not the case for the splice donor sequence in the intron upstream of the 87-bp exon, which may account for its alternative recognition by the splicing machinery, possibly itself a regulated mechanism. As the 87-bp exon does not contain any splicing consensus sequence, the $D_{2(444)}$ receptor mRNA does not represent an immature mRNA precursor of the shorter form.

Both isoform mRNAs seem to be expressed in all areas of the brain and pituitary in which the D_2 receptor is found[4,9], as indicated by northern analysis using either a probe selective for



Exon	Splice donor	Splice acceptor	Exon

B	AGAATGgtaagtgt.......ttccacagGATGCT		C

FIG. 2 Diagram of the D_2 receptor gene showing the alternative splicing sites. Indicated are the positions of introns (lines) and exons (boxes), including the 87-bp exon selectively translated in the case of the $D_{2(444)}$ receptor isoform (shaded box). The corresponding amino acids flanking the exons are also indicated and numbered according to the sequence of the $D_{2(444)}$ receptor isoform. Restriction sites and primers refer to those used to prepare probes for northern blotting and to initiate the PCR as shown in Fig. 3.

METHODS. A rat genomic library (from Dr A. M. Duchemin) constructed in Charon 4A phage from DNA partially digested with *Eco*RI was screened (10^6 phage) using as probe a ^{32}P-labelled nick-translated 1.3-kb *Bam*HI–*Bgl*II fragment of the $D_{2(444)}$ receptor cDNA. Nitrocellulose filters with transferred phage were hybridized for 16 h at 42 °C in 40% formamide, 10% dextran sulphate, 4 × SSC, 8 mM Tris-HCl, pH 7.4, 1 × Denhardt's, 20 μg ml^{-1} yeast tRNA, 20 μg ml^{-1} salmon sperm DNA, 0.1% SDS, using probe at 5×10^5 d.p.m. ml^{-1}. The filters were washed as described in the legend to Fig. 1, except that the last washing was for 30 min at 50 °C. In positive clones, *Eco*RI restriction generated fragments 0.8, 4.5 and 5.5 kb long, all of which hybridized to the *Bam*HI–*Bgl*II probe. The 4.5-kb fragment also hybridized to a probe prepared by ^{32}P-nick translation of the *Rsa*I–*Sac*I fragment of $D_{2(444)}$ receptor cDNA, whereas the other two did not. This fragment was subcloned in M13 mp18 and sequenced using primers located around and within the 87-bp sequence.

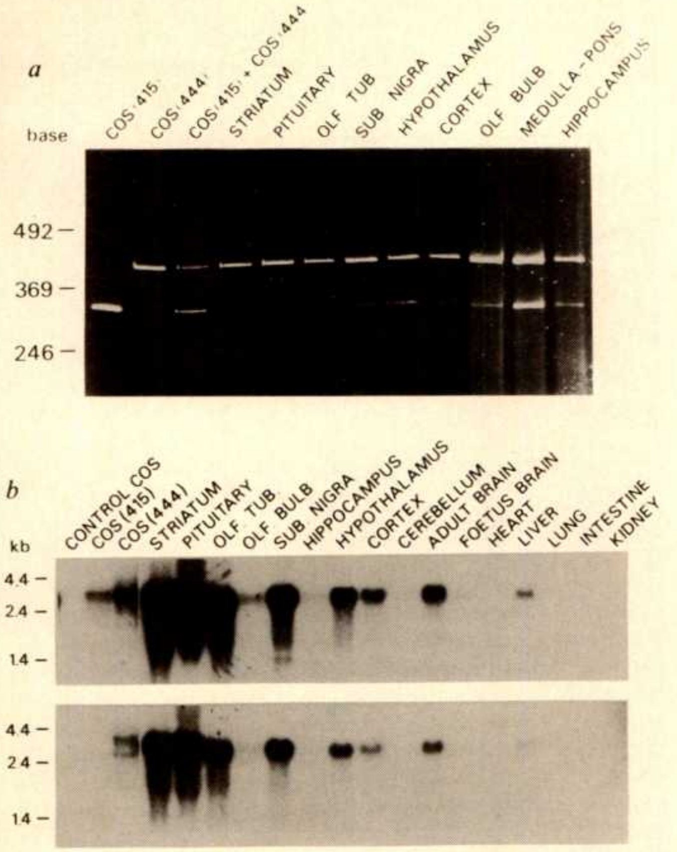

FIG. 3 Characterization of two D_2 dopamine receptor mRNAs. *a*, Northern blot analysis of total RNA from COS-7 cells (10 μg) or poly(A)$^+$ mRNA from rat tissues (5 μg), using as probes either a 241-bp *Sac*I–*Afl*II fragment (top) corresponding to a common sequence of the two isoforms or a 95-bp *Rsa*I–*Sac*I fragment (bottom; different blots from the same samples) corresponding mainly to the alternative exon (Fig. 2). *b*, Electrophoresis of PCR products from RNA using two primers flanking most of the putative third cytoplasmic loop (Fig. 2). The 397- and 310-base products correspond to the $D_{2(444)}$ and $D_{2(415)}$ receptor mRNAs, respectively. Abbreviations: COS(415) and COS(444), COS-7 cells transfected with $D_{2(415)}$ and $D_{2(444)}$ receptor cDNAs respectively; olf. tub., olfactory tubercle; olf. bulb., olfactory bulb; sub. nigra, substantia nigra; cortex, cerebral cortex; foetus brain, brain from gestational day-15 foetus; intestine, duodenum plus ileum.

METHODS. Total RNA was extracted[22] and poly (A)$^+$ mRNA prepared[23] from tissues of male Wistar rats (except for pituitaries, which were from oestradiol-treated females[25]) and COS-7 cells. *Xho*I–*Sal*I fragments of recombinant pGEM-4Z containing $D_{2(415)}$ or $D_{2(444)}$ cDNAs were ligated into the *Xho*I restriction site of the pMAMneo inducible expression vector (Clontech). These constructs (30 μg) were transfected[26] into mouse COS-7 cells (from Dr J. J. Rémi). Transformed cells were selected in 500 μg ml^{-1} G418 and 48 h after transfection, expression was induced by a 12–24 h treatment with 10 μM dexamethasone. For northern blotting, denaturated RNAs were electrophoresed in 1% agarose/formaldehyde gels, blotted onto nitrocellulose paper and baked for 2 h at 80 °C. Membranes were hybridized overnight at 42 °C in 40% formamide, 10 × Denhardt's, 50 mM Tris-HCl, pH 7.4, 4 × SSC, 0.1% sodium pyrophosphate, 1% SDS, 100 μg ml^{-1} salmon sperm DNA and 50 μg ml^{-1} yeast tRNA containing a ^{32}P-labelled nick-translated fragment at 5×10^6 d.p.m. ml^{-1}. For PCR experiments, a single-strand cDNA was synthesized using AMV reverse transcriptase (20 U; Boehringer), primer 2 (5′-GCTTTCTGCGGCTCATCGTCTTAA; Eurogentech) and total RNA (from COS-7 cells containing identical amounts of specific mRNA, as assessed by northern blotting) or 1–6 μg poly(A)$^+$ mRNA (rat tissues). This template was amplified[12], using primer 1 (5′-TTCAGAGCCAACCTGAAGACACCA) and primer 2 (80 nM each) for 35 cycles (92 °C, 54 °C and 72 °C, for 1 min each), with 2.5 U *Taq* DNA polymerase (Perkin Elmer Cetus); 10–20% of PCR products were run on 6% polyacrylamide-urea gel which was stained in ethidium bromide and scanned.

the $D_{2(444)}$ receptor mRNA, or a probe hybridizing to both mRNAs (Fig. 3). In all these tissues, the first probe generated a signal, indicating unambiguously that the $D_{2(444)}$ receptor mRNA was expressed, and its intensity grossly paralleled the relative abundance of D_2 receptors[9]. Interestingly, a faint but distinct signal was also detected with mRNAs from liver, a tissue in which D_2 receptor may be expressed prenatally[10]. In all these tissues, the second probe also generated a signal of apparently parallel relative intensity, but we could not establish from it whether the $D_{2(415)}$ receptor mRNA was also expressed, or its relative abundance. But, using the polymerase chain reaction (PCR)[11,12], we clearly identified the two mRNA isoforms in brain and pituitary from two bands of the predicted sizes (Fig. 3) that hybridized with the *Sac*I–*Afl*II probe (data not shown). The $D_{2(415)}$ receptor mRNA seems to be the least abundant in all regions tested, representing 2% in pituitary, 12% in olfactory

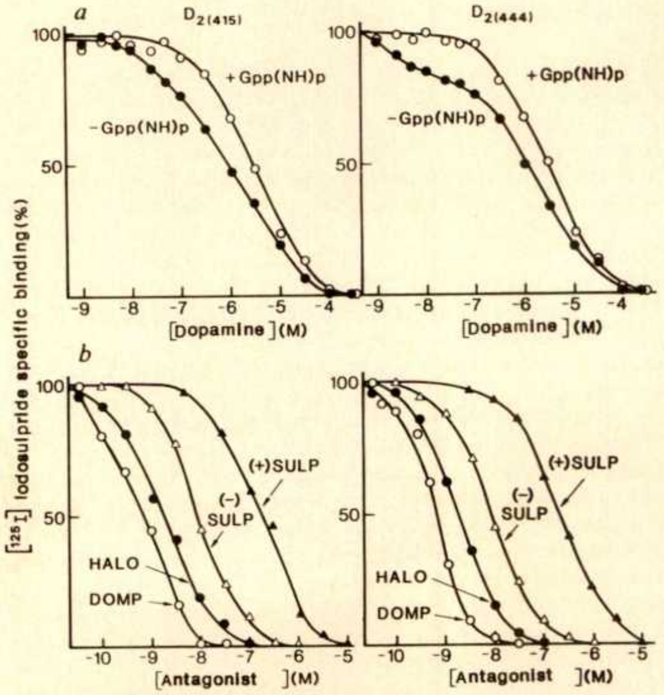

FIG. 4 [^{125}I]iodosulpride binding to the two D_2 receptor isoforms in transfected COS-7 cells. Specific binding of 0.4 nM [^{125}I]iodosulpride (about 2,000 Ci mmol^{-1}; Amersham) represented 100–150 and 150–200 fmol per mg protein in membranes of COS(415) and COS(444) cells respectively. *a*, Effect of Gpp(NH)p, a guanyl nucleotide, on the dopamine inhibition of [^{125}I]iodosulpride binding to $D_{2(415)}$ and $D_{2(444)}$ receptors. In the absence of Gpp(NH)p, dopamine inhibited the specific [^{125}I]iodosulpride binding in a biphasic manner, giving the following IC_{50} values and relative proportions of sites (in parentheses); 120 ± 40 nM (46%) and 6,500 ± 2,900 nM with the $D_{2(415)}$ receptor; 4.7 ± 2.8 nM (22%) and 1,900 ± 420 nM with the $D_{2(444)}$ receptor. In the presence of 0.1 mM Gpp(NH)p, only one site could be detected with IC_{50} values of 2,290 ± 300 nM and 2,490 ± 260 nM for the $D_{2(415)}$ and $D_{2(444)}$ receptors respectively. Means from 3 separate experiments. *b*, Inhibition of specific [^{125}I]iodosulpride binding by various dopaminergic antagonists gave similar IC_{50} values (nM) for the $D_{2(415)}$ and $D_{2(444)}$ receptor isoforms respectively: 0.64 ± 0.10 and 0.61 ± 0.06 with domperidone (DOMP); 1.3 ± 0.1 and 1.3 ± 0.2 with haloperidol (HAL); 9.1 ± 0.5 and 7.9 ± 0.3 with (−)sulpiride ((−)SULP); 190 ± 30 and 170 ± 20 with (+)sulpiride ((+)SULP). Values are means from 2–4 separate experiments.

METHODS. COS-7 cells were scrapped, collected by centrifugation at 1,500*g* for 5 min and washed in 15 mM Tris-HCl buffer, pH 7.4, containing 5 mM $MgCl_2$. After cell disruption, membranes were isolated by centrifugation (twice at 25,000*g* for 10 min) in the same buffer. Binding was assayed in 50 mM Tris-HCl pH 7.4 120 mM NaCl, 5 mM KCl, 2 mM $CaCl_2$, 2 mM $MgCl_2$, 5.6 mM ascorbic acid and 0.1 mM 8-hydroxyquinoleine[9]. Non-specific binding measured in the presence of 1 μM (−)sulpiride typically represented 20–25% of total binding. Curves were analysed by computerized nonlinear regression using a one- or a two-site model[25].

bulb, 20–25% in striatum, olfactory tubercle, substantia nigra, cortex and hippocampus, 40–45% in hypothalamus and pons-medulla. This indicates that the relative level of expression of the two isoforms is tissue-specific.

When expressed in COS-7 cells, which normally lack D_2 receptors, the two receptor isoforms displayed similar pharmacology when studied using $[^{125}I]$iodosulpride, a highly selective D_2 receptor ligand[9] (Fig. 4). This agrees with the idea, derived from site-directed mutagenesis and chimaera construction, that the ligand-binding domain for this family of receptors resides in the transmembrane segments[13,14], which are identical in the two isoforms. It should be emphasized that neither the $D_{2(415)}$ nor the $D_{2(444)}$ receptor display the high affinity for benzamide derivatives which is characteristic of a putative D_2 receptor subtype[5,6]. Both isoforms are apparently coupled to a G protein or proteins in the COS-7 cells, as judged from the modulation of dopamine affinity by a guanyl nucleotide (Fig. 4); this confirms that the absence of this feature in the $D_{2(415)}$ receptor when it is expressed in L cells results from the absence of a suitable G protein, presumably a G_i protein, in the recipient cell[7].

Hence a sizeable deletion in the third cytoplasmic loop, thought to be the domain through which these receptors couple to G proteins, does not prevent coupling; this is consistent with results from deletion mutagenesis[13] and limited trypsinization in β-adrenergic receptors[15]. The significant variation in size and sequence of this loop among receptors of this family may reflect their selective interactions with members of the G-protein family, whose diversity probably results both from multiple genes and alternative splicing[16]. The slightly different pattern of Gpp(NH)p modulation observed with the two receptor isoforms in COS-7 cells (Fig. 4) could reflect either their interaction with different G proteins, or a different interaction with the same G protein.

For neurons, which are long-lived cells that have lost their ability to replicate DNA, alternative splicing is a reversible post-transcriptional mechanism that enables different proteins to be rapidly generated in response to environmental stimuli[17]. The selective tissue expression of the D_2 receptor isoforms by this process reveals a new paradigm in the generation of diversity among members of an already large family and raises questions about the underlying mechanisms and functional implications of this process and their disturbance. For instance, an increased number of D_2 receptors have been detected in the brains of schizophrenic patients and/or following their long-term treatments with antipsychotics[18,19]; it will be interesting to determine which isoforms are involved and whether these changes have aetiological or therapeutic implications. □

DOPAMINE receptors belong to a large class of neurotransmitter and hormone receptors that are linked to their signal transduction pathways through guanine nucleotide binding regulatory proteins (G proteins). Pharmacological, biochemical and physiological criteria have been used to define two subcategories of dopamine receptors[1] referred to as D_1 and D_2. D_1 receptors activate adenylyl cyclase[2] and are coupled with the G_s regulatory protein[3]. By contrast, activation of D_2 receptors results in various responses including inhibition of adenylyl cyclase[4], inhibition of phosphatidylinositol turnover[5], increase in K^+ channel activity[6] and inhibition of Ca^{2+} mobilization[7]. The G protein(s) linking the D_2 receptors to these responses have not been identified, although D_2 receptors have been shown to both copurify[8,9] and functionally reconstitute[10,11] with both G_i and G_o related proteins[3]. The diversity of responses elicited by D_2-receptor activation could reflect the existence of multiple D_2 receptor subtypes, the identification of which is facilitated by the recent cloning of a complementary DNA encoding a rat D_2 receptor[12]. This receptor exhibits considerable amino-acid homology with other members of the G protein-coupled receptor superfamily[12,13]. Here we report the identification and cloning of a cDNA encoding an RNA splice variant of the rat D_2 receptor cDNA[12]. This cDNA codes for a receptor isoform which is predominantly expressed in the brain and contains an additional 29 amino acids in the third cytoplasmic loop, a region believed to be involved in G protein coupling.

To isolate cDNAs encoding dopamine receptor subtypes, we initially constructed a λ ZAP II cDNA library using mRNA purified from rat striatum, the region of the brain known to contain the highest levels of both D_1 and D_2 dopamine receptors[1]. This library was screened with a mix of two 36-mer synthetic oligonucleotides, the sequences of which were derived from amino acids 352–363 of the rat D_2 receptor cDNA[12]. This region corresponds to the sixth transmembrane-spanning domain and is known to exhibit very high homology among previously cloned G protein-coupled receptors[13]. From 1×10^6 recombinants, 15 positive clones were isolated. Restriction analysis and partial sequence information indicated that 5 of these clones were related to the rat D_2 receptor cDNA reported previously[12]. One of the clones containing an insert of 2.5 kilobases (kb) was completely sequenced and the nucleotide and deduced amino-acid sequence of this cDNA is shown in Fig. 1. The longest open reading frame in this cDNA codes for a 444 residue protein with a relative molecular mass (M_r) of

FIG. 1 Nucleotide and deduced amino-acid sequence of the D_2 receptor cDNA clone. The 87-bp/29 amino-acid insertion sequence is indicated by underlining. The nucleotide sequence is numbered from the initiator Met and indicated at the left of each line. The amino-acid numbers are indicated at the right of each line. The single base differences in the 3' untranslated sequence are indicated by dots.

METHODS. Poly(A)$^+$ RNA was isolated from rat striatal tissue using standard procedures[22] and used to construct a cDNA library in the λ ZAP II vector (Stratagene). The resulting library contained 6.1×10^6 independent recombinants. 1×10^6 recombinants from the unamplified library were screened using the oligonucleotide 5'-GATGAAGAAGGGCAGCCAGCAGATGATGAACACA(G)CC-3' radiolabelled using [γ-^{32}P]ATP and T4 polynucleotide kinase. Duplicate nitrocellulose filters were hybridized in 0.3 M NaCl/0.03 M sodium citrate (2×SSC), 0.02 M Na_2HPO_4, 0.1% SDS, 0.2 mg ml^{-1} salmon sperm DNA, and 4×10^6 d.p.m. ml^{-1} ^{32}P-labelled probe for 18 h at 42 °C. High stringency washing of the filters was performed with 0.5×SSC and 0.1% SDS at 60 °C before autoradiography. Phage λ found to hybridize to the probe were subsequently plaque-purified. *In vivo* excision and rescue of the nested pBluescript plasmids from the λ ZAP II clones were performed using helper phage according to the Stratagene protocol. Nucleotide sequence analysis was performed using the Sanger dideoxy nucleotide chain termination method on denatured doubled-stranded plasmid templates with Sequenase (US Biochemical Corp.). Primers were synthetic oligonucleotides which were either vector-specific or derived from previous sequence information. In some cases a series of nested deletion mutants were constructed using the *Exo* III/Mung Bean nuclease procedure (Stratagene) before DNA sequencing.

50,887. The nucleotide and amino-acid sequence within this coding region is identical to the rat D_2 receptor cDNA previously reported with the notable exception of an additional 87 base pair (bp) sequence coding for a 29 amino-acid insertion between residues 241 and 242 (ref. 12). This is located within the predicted third cytoplasmic loop ~30 residues from the C terminus of the fifth transmembrane-spanning domain. In addition to this insertion sequence, and a slightly extended 5' untranslated sequence, we also noted five base differences within the 3' untranslated region compared with the previously published sequence[12] (Fig. 1). Subsequent sequence analysis indicated that all five of the D_2 receptor-related cDNAs initially isolated from this library contained the identical 87-bp insertion sequence. The nucleotide sequences delineating the boundaries of this insertion sequence correspond with consensus exon sequences for RNA splice junctions[14], indicating that this cDNA results from alternative RNA splicing. The alternative hypothesis, that the different cDNAs are derived from separate genes, is unlikely given the observation that an oligonucleotide probe corresponding to an identical sequence in the two cDNAs (Fig. 2*a*) hybridizes to single DNA fragments on Southern blots of rat genomic DNA cut with a number of different restriction enzymes (data not shown).

To confirm the D_2-subtype identity of this longer cDNA clone and to determine if the 29 amino-acid insertion sequence results in a major alteration in the ligand binding properties of the D_2 receptor, the cDNA was inserted into the SV40 promoter-driven vector, pEUK-C1 (ref. 15), for expression in eukaryotic cells. The resulting plasmid (pEUK-D2L) was used to transiently transfect COS-7 cells by the calcium phosphate precipitation technique[16]. After 3 days, membranes were prepared and the binding of the D_2 dopaminergic antagonist [^{3}H]methylspiperone was examined[17]. In three separate transfection experiments, [^{3}H]methylspiperone bound to the membranes in a saturable fashion with high specific activity ($\sim$1 pmol mg^{-1} protein) and an affinity (62.1 ± 2.1 pM) in good agreement with that found in the rat striatum[1]. No specific binding activity was detected in COS-7 cells that had not been transfected with pEUK-D2L or transfected with the pEUK-Cl vector alone. The ability of a variety of dopaminergic ligands to compete for specific [^{3}H]methylspiperone binding to transfected COS-7 cell membranes was also investigated in these experiments. The high affinity D_2-selective antagonist spiperone (36 ± 3.8 pM) is the most potent agent, followed by the nonselective dopaminergic antagonist (+)butaclamol (0.52 ± 0.01 nM), which is more than four orders of magnitude more potent than its inactive isomer, (−)butaclamol ($>10\ \mu$M). The D_2-selective antagonist (−)sulpiride (7.9 ± 0.42 nM) also exhibits high affinity whereas the D_1-selective antagonist SCH-23390 ($0.41 \pm 0.047\ \mu$M) does not. The Hill coefficients for these antagonist competition curves do not differ significantly from unity. Dopamine is also able to inhibit completely [^{3}H]methylspiperone binding ($K_i = 0.71 \pm 0.012\ \mu$M), although the competition curve is homogeneous (Hill coefficient $\sim$1) and not significantly affected by guanine nucleotides indicating the absence of appropriate G-protein coupling[18] in the COS-7 cells. This rank order of potency as well as the absolute affinities (K_i) of the antagonists agree with those demonstrated for brain D_2 receptors[1], as well as those for the D_2 receptor encoded by the previously cloned cDNA[12]. These preliminary experiments thus indicate that the insertion sequence does not appear to affect the basic ligand recognition properties of the D_2 receptor.

To verify the expression of the D_2 receptor variant containing the insertion sequence and determine the relative proportions of the two receptor isoforms, we subjected various rat tissues to northern blot analysis using an oligonucleotide probe to a consensus region (Fig. 2*a*) as well as an insert sequence-specific

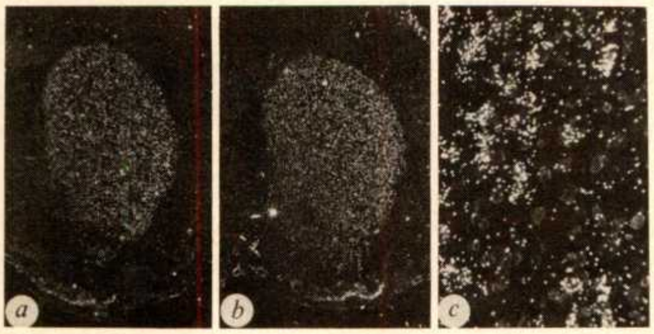

FIG. 2 Northern blot analysis of D_2 receptor transcripts in brain and other rat tissues. Each lane contained 2 μg poly(A)$^+$ RNA. Lanes: 1, total brain; 2, cerebellum; 3, cortex; 4, hippocampus; 5, olfactory bulb; 6, mesencephalon; 7, retina; 8, kidney; 9, striatum; 10, pituitary. The gel locations of the RNA size markers (kb) are indicated. *a*, Blots hybridized with an oligonucleotide derived from amino acids 10–25 (Fig. 1): 5′-TGACCCATTGAAGGGCC-GGCTCCAGTTCTGCCTCTCCAGATCGTCATC-3′. *b*, Hybridization performed with an insert sequence oligonucleotide derived from amino acids 242–257 (Fig. 1); 5′-CATGATAACGGTGCAGAGTTTCATGTCCTCAGGGTGGGTACAGTTG-CC-3′. This experiment was performed twice with similar results.

METHODS. Poly(A)$^+$ RNA was isolated from rat tissues using standard procedures[22] which included 2–3 passages over oligo(dT) cellulose. This procedure resulted in mRNA of high purity nearly devoid of 28S and 18S rRNA. After electrophoresis on 1% agarose plus 0.66 M formaldehyde gels and blotting, the filters were prehybridized in 4 × SSPE, 5 × Denhardt's solution, 50% formamide, 250 μg ml^{-1} yeast tRNA, 500 μg ml^{-1} sheared salmon sperm DNA, and 0.1% SDS for 16 h at 37 °C. The filter blots were then hybridized in the same solution for 18 h at 37 °C with 2×10^6 d.p.m. ml^{-1} oligonucleotide probe radiolabelled with [α-^{32}P]ATP and terminal deoxytransferase. The blots were washed in 1 × SSPE and 0.1% SDS for 20 min four times at 56 °C and twice at room temperature before autoradiography.

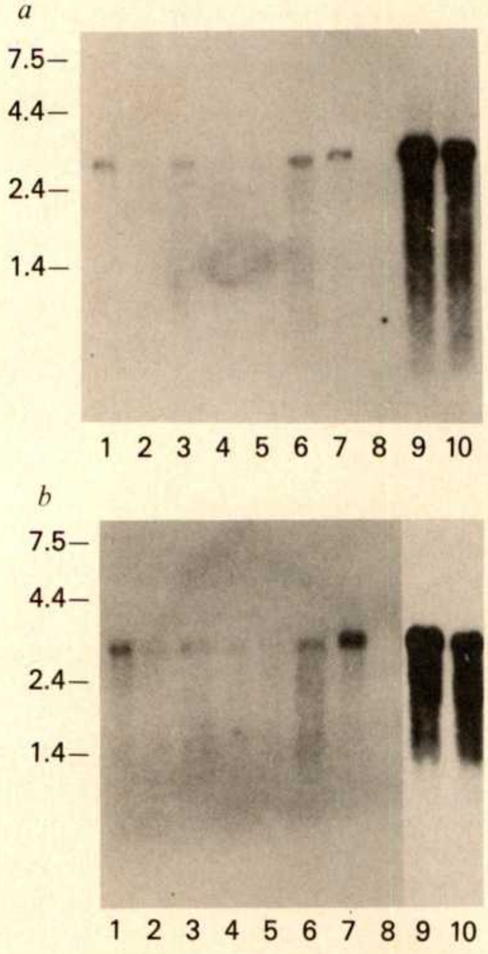

FIG. 3 Darkfield photomicrographs (silver grains appear white) of *in situ* hybridization histochemical (ISHH) localization of D_2 receptor mRNA in a coronal section of rat brain which includes the striatum. *a*, ISHH labelling using the ^{35}S-labelled oligonucleotide from Fig. 2*a*. *b*, ISHH labelling using the ^{35}S-labelled oligonucleotide from Fig. 2*b*. In both sections the labelling of cells is most dense in the striatum and olfactory tubercle. *c*, High power magnification of labelling from *b* showing localization of D_2 receptor mRNA in a subset of medium-sized neurons in the striatum. Approximately half of the medium-sized cells are labelled by this procedure.

METHODS. Coronal sections through the striatum were cut in a cryostat and adhered to glass slides that had been twice coated with gelatin. Sections were fixed in a 4% paraformaldehyde solution in 0.9% saline for 10 min, rinsed and incubated in a fresh solution of 0.25% acetic anhydride in 0.1 M triethanolamine and 0.9% saline (pH 8) for 10 min, dehydrated in ethanol and defatted for 2 × 5 min in chloroform, rehydrated and air-dried. These sections were then hybridized with the ^{35}S-dATP tailed oligonucleotide probes and processed as previously described[23]. Subsequently, the slides were dipped in NTB3 emulsion (diluted 1:1 with water) and exposed for 4–6 weeks, after which they were developed in D-19 developer for 2 min, fixed, rinsed, counterstained with thionin, dehydrated and coverslipped out of xylene.

probe (Fig. 2*b*). As shown in Fig. 2, the tissues expressing the highest levels of the 2.9-kb D_2 receptor mRNA are the striatum and pituitary. The retina shows a moderate abundance of mRNA with low levels being observed in the mesencephalon and cortex and trace quantities detected in the olfactory bulb and hippocampus. Little mRNA was found in the cerebellum and kidney. This tissue distribution corresponds closely to that previously determined for D_2 receptor expression[1]. Of interest, however, is the fact that in all of the tissues examined, the amount of mRNA detected with the two probes is very similar (Fig. 2) and in no instance did the consensus probe detect greater quantities of mRNA.

To investigate further the relative distributions of the two mRNAs encoding the D_2 receptor isoforms we performed *in situ* hybridization analysis in the rat forebrain with the two oligonucleotide probes used in Fig. 2. Figure 3 shows darkfield photomicrographs of *in situ* hybridization histochemical localization of D_2 receptor mRNA in a coronal section of rat brain which includes the striatum. As can be seen, identical patterns of labelling were obtained using both the consensus region probe and the insert sequence probe (Fig. 3*a*, *b*). The highest labelling occurred in the striatal neurons where $\sim$50% of the medium sized neurons were labelled (Fig. 3*c*). Larger sized neurons in the striatum also exhibited labelling (data not shown).

It is interesting that in Figs 2 and 3 there did not appear to be any difference in the levels of mRNA detected using the two oligonucleotide probes. If any tissue or brain area expressed mRNA containing the insertion sequence at a level equal to or less than the one lacking the insertion, then the consensus probe should detect mRNA levels that are at least twofold greater than those seen with the insert probe. These experiments thus indicate that not only is the longer D_2 receptor variant (which we propose designating D_{2L}) expressed in brain and other tissues, but in those areas which have been examined (especially the striatum), it appears to be the major isoform. Exploring this further, we rescreened our unamplified rat striatal cDNA library at high stringency using the full length D_{2L} receptor cDNA as a probe, which resulted in the isolation of $\sim$24 D_2-receptor-positive clones. Partial sequence analysis indicated that only three of these clones correspond to the previously isolated cDNA[12] encoding the shorter D_2 receptor (now designated D_{2S}). This indicates that the D_{2S} receptor is, in fact, expressed in the striatum, albeit in low abundance. Further experiments directed at determining the actual levels of the receptor proteins will be required to confirm this point.

With the exception of the visual opsins, the genes for the G protein-coupled receptor family have, in most instances, demonstrated a lack of introns within their coding sequences[13] thus precluding the generation of receptor diversity through alternative RNA splicing. Recently, however, it has been determined that the serotonin 5HT$_{1C}$ (B.J. Hoffmann, personal communication) and D_2 dopamine[12] receptors are encoded by genes that contain introns. Our data on the rat D_2 receptor now provides an example of G protein-coupled receptor isoforms generated through alternative RNA splicing. These isoforms, which are defined by the presence or absence of a 29-amino-acid sequence within the receptor protein, could arise either through the existence of a 'cassette exon' or through alternative internal acceptor or donor sites within the precursor mRNA[19]. The isolation and sequencing of the rat D_2 receptor gene will be required to distinguish among these possibilities. The location of this optional amino-acid sequence is particularly intriguing as it occurs within the predicted third cytoplasmic loop of the receptor[12]. Recent mutagenesis studies using the β_2-adrenergic catecholamine receptor have indicated that this region is involved in G protein-receptor coupling[20,21]. It is thus tempting to speculate that the two D_2 receptor isoforms are coupled to different G proteins thus resulting in the diversity of responses associated with D_2 receptor activation[4-7]. Further work involving the stable expression of the two D_2 receptor isoforms in cells exhibiting appropriate G protein-linked effector systems will be required to test this hypothesis. □

Mechanism of antigen-driven selection in germinal centres

Y-J. Liu*, D. E. Joshua*, G. T. Williams†, C. A. Smith†, J. Gordon* & I. C. M. MacLennan*‡

Departments of Immunology* and Anatomy†,

THE high affinity of antibodies produced during responses to T-cell-dependent antigens is associated with somatic mutation in the variable region of the immunoglobulin[1-4]. Indirect evidence indicates that: (1) this arises by a process of hypermutation, acting selectively on rearranged immunoglobulin variable-region genes, which is activated in centroblasts within germinal centres; and (2) centrocytes, the progeny of centroblasts, undergo selection on the basis of their ability to receive a positive signal from antigen[5]. We have now performed experiments analysing this selection process, and found that, on culture, centrocytes isolated from human tonsil kill themselves within a few hours by apoptosis[6]. This is not a feature of other tonsillar B cells. Centrocytes can be prevented from entering apoptosis if they are activated both through their receptors for antigen and a surface glycoprotein recognized by CD40 antibodies[7,8].

Immunohistological studies have shown that B cells undergo a marked phenotypic change when they participate in germinal-centre reactions[8]. The lack of surface IgD and CD39 antigen on either centroblasts or centrocytes was used to isolate human germinal-centre B cells by negative selection from suspensions of medium- and low-density tonsillar B cells (Table 1). The phenotype of the resulting CD39-IgD-negative fraction (Table 1) corresponds with that defined for germinal-centre B cells using immunohistology[8]. These cells show good viability at the end of the isolation procedure, carried out at 4 °C. When these cells were cultured at 37 °C they began to show signs of apoptosis (Fig. 1*a*). This process resulted in the loss of $\sim$75% of the cells within 16 h, with no cells surviving 40 h (Table 2). By contrast, apoptosis was not a feature either of the medium-to-low density tonsillar B cells that expressed CD39 or IgD, or both, or of dense tonsillar B cells (Table 2). Similar results were obtained when germinal-centre cells were positively selected for expression of CD38 (Table 2). Apoptosis in the germinal-centre cell-enriched preparation was confirmed by: (1) finding the characteristic DNA fragmentation, caused by endonuclease activity which cuts DNA at intervals of about 180 bases[6], using methods described previously[9]; and (2) identifying the morphological features of apoptosis, which include chromatin condensation with nuclear fragmentation, by both conventional (Fig. 1*a*) and electron microscopy[6].

Follicular dendritic cells take up antigen, in the form of immune complex, and retain this for extended periods[10,11]. These may provide a means for antigen-driven B-cell selection. A series of experiments were carried out to see if apoptosis in isolated germinal-centre cells could be prevented by exposing the cells to a range of antibodies to human immunoglobulins. None of these prevented apoptosis when added in soluble form to cultures. When polyspecific anti-immunoglobulin was conjugated to sheep red blood cells and added to cultures, however, it inhibited apoptosis (Table 3*a*, Fig. 1*b*). This protective effect was also obtained with anti-IgG, but not with other immunoglobulin class-specific antibodies bound to red cells (Table 3*b*). IgG was the only class of immunoglobulin expressed on a substantial proportion of isolated germinal-centre cells (Table 1).

Germinal-centre B cells were not prevented from entering apoptosis when they were cultured with a range of other agents that stimulate B cells. Among such agents tested were the recombinant cytokines, interleukin (IL)-1, IL-2, IL-3, IL-4, IL-5, IL-6 and IL-7, CD23 antibody, gamma and alpha interferon and supernatant from mixed lymphocyte reaction cultures (data not detailed). These agents were all added in concentration ranges known to be biologically active in control human B-cell cultures. By contrast, the addition of soluble CD40 antibody greatly reduced the number of cells entering apoptosis (Table 3*a*). Although anti-immunoglobulin and CD40 were effective in delaying the onset of apoptosis, neither agent used in isolation was able to sustain viability beyond 2 days of culture. Good survival after 4 days of culture was obtained when the two agents were added in combination (Table 3*a*). The CD40 effect could reflect a microenvironment-dependent signal.

The trigger for apoptosis in cultured germinal-centre cells is unclear. It is unlikely that the cells are killed by cytolytic lymphocytes, because apoptosis continues in the absence of extracellular divalent cations (data not shown). This was demonstrated using techniques described in ref. 12. Calcium, and to a lesser extent Mg^{2+}, are required for lymphocyte-mediated

TABLE 1 Phenotype of tonsil B cells

	B-cell fraction	
Antigen detected	Enriched for germinal-centre cells (sCD39 −ve and sIgD −ve)	Depleted of germinal-centre cells (sCD39 +ve and/or sIgD +ve)
sCD19	85 (79–95)	88 (84–98)
sCD10	74 (65–80)	22 (15–30)
sCD38	86 (81–92)	32 (23–50)
sCD39	0 (0–2)	53 (38–75)
sCD3	0 (0–0)	0 (0–0)
sIgG	47 (28–52)	34 (24–43)
sIgM	3 (1–16)	26 (24–37)
sIgD	0 (0–0)	60 (54–70)
sIgA	0 (0-0)	2 (1–4)
Alpha-NAE	5 (4–5)	3 (3–3)

The phenotype of tonsil B cells either enriched for germinal-centre cells by removal of cells binding CD39 antibody or anti-IgD, or both, or depleted of germinal-centre cells. The values shown are the median value for the percentage of cells positive, based on five experiments, with the range in parentheses. Tonsil B cells were prepared as previously described[24]; all separation procedures were performed at 4 °C. High-density cells which lack the features of germinal-centre B cells were removed by centrifugation through a 60% Percoll gradient. The remaining cells were mixed with sheep red cells coated with CD39 antibody AC-2 (ref. 8) and red cells coated with sheep anti-human IgD. After 30 min, the non-rosetting, germinal-centre cell-enriched fraction was separated from the rosetting fraction using Ficoll-isopaque density gradient centrifugation. The surface (s) phenotype of the cells was determined using the direct antibody rosette technique[25]. The nuclei of the cells were stained with 0.002% acridine orange to identify cells undergoing apoptosis and nonmononuclear cells. These were excluded from the counts. Alpha-napthyl-acetate esterase (alpha-NAE) activity, used to identify macrophages, was revealed as described in ref. 26. The following monoclonal antibodies were used: CD19, an antigen present on all B cells (BU-12; ref. 8); CD10, CALLA, present on germinal-centre B-lineage cells but not other tonsil B cells (AL2; ref. 27); CD38, identifies germinal-centre B-lineage cells and plasma cells, but not other B cells found in the tonsil (OKT10; ref. 28); CD39, an antigen present on most tonsilar B cells, other than germinal-centre B-lineage cells, as well as some macrophages and plasma cells (AC-2; ref. 8); CD3, present on all T cells (OKT3; ref. 29); anti-IgG (8A4; ref. 30); anti-IgM (AF6; ref. 8). Sheep antibodies against human: IgA, IgD and IgM and IgG were used (The Binding Site, Birmingham, UK). Abbreviations: +ve, positive; −ve, negative.

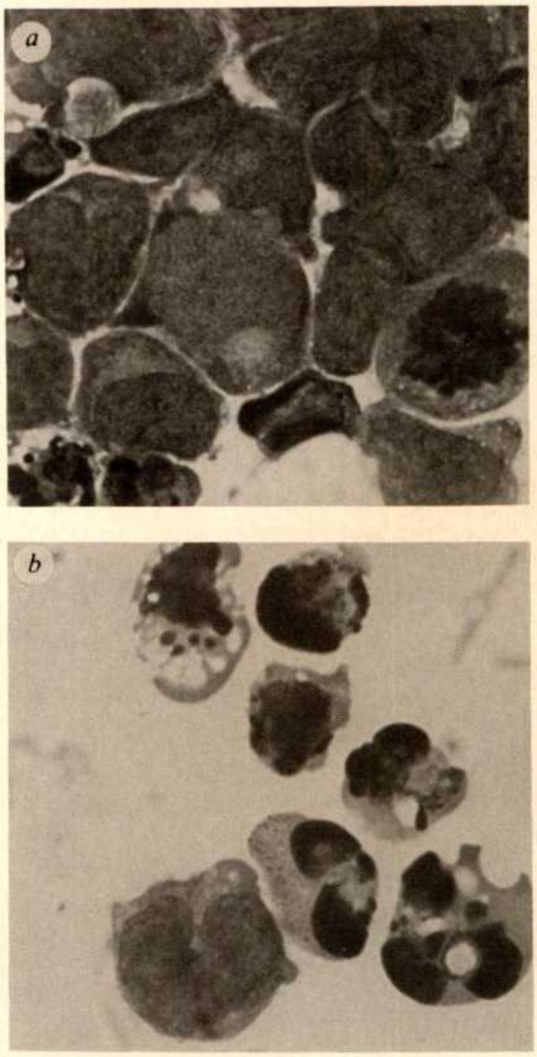

FIG. 1 *a*, Cells from the germinal-centre cell fraction of human tonsil after 6 h culture as described in Table 1. One intact centroblast is seen with six apoptotic cells which show the nuclear condensation and fragmentation which characterize this process[6]. This is a Romanowski-stained cytocentrifuge preparation photographed at a microscope magnification of ×1,000. *b*, Cells from the same germinal-centre fraction depicted in *a*, cultured with sheep red cells coated with polyvalent anti-human immunoglobulin for 16 h as described in Table 1. Staining and photography as in *a*. Blast cells with frequent mitotic figures characterize these preparations. The cells tend to grow in clusters with some apoptotic cells still found at the periphery of these clusters.

TABLE 2 Selective cell death in germinal-centre B cells

Tonsil B-cell fraction	% cells recovered from cultures after: 16 h	40 h	72 h	96 h
High-density resting B cells	96–99	60–81	54–58	30–39
Low- and medium-density CD39 and sIgD −ve	22–26	0–0	0–0	0–0
Low- and medium-density CD39 and/or sIgD +ve	64–73	48–56	41–50	20–30
Low- and medium-density CD38 +ve	38–42	19–21	10–12	2–8
Low- and medium-density CD38 −ve	87–95	68–90	68–90	50–85

The first three tonsil B-cell fractions were prepared as described in Table 1, the CD38 positive (+ve) and CD38 negative (−ve) fractions were prepared in a similar way using CD38-coated sheep red cells. The CD38 +ve fraction contains all germinal-centre B-lineage cells but does include some cells from outside germinal centres (Table 1). Cell fractions were cultured for the periods indicated in flat-bottomed microtitre wells at 37 °C in a moist atmosphere of 5% CO_2 in air in 200 μl of RPMI 1640 medium enriched with 10% fetal bovine serum. The starting cell concentration was 2×10^5 cells per ml. The number of viable cells recovered in two separate experiments from wells after the periods of culture indicated is shown. Cell viability was assessed by trypan-blue exclusion.

cytolysis[12,13]. The macrophage content of the germinal-centre cell fraction (Table 1) is similar to that in the fraction positive for CD39 or IgD, or both. It is difficult to understand why there should be selective macrophage-mediated lysis of the germinal-centre cells and why this should be inhibited by CD40. If the germinal-centre cells are not being killed, they must be killing themselves. The high physiological cell death rate among these cells *in vivo*[14,15], together with the finding that other tonsil B cell populations do not destroy themselves by apoptosis on culture (Table 2), seems to argue against this being an artefact of the culture system.

Affinity maturation of antibodies in responses to T-cell-dependent antigens is mainly attributable to alteration of the structure of the immunoglobulin variable region by somatic mutation[4]. The time of onset of this somatic mutation[16] correlates with the start of the germinal-centre reaction[15,17]. Other features consistent with a link between these processes have been described previously[5]. Mutations can increase, decrease or fail to modify the affinity of antibodies. The experiments reported here indicate how centrocytes with low affinity for antigen can be eliminated. The germinal-centre cells with high affinity are most likely to be those which survive to give rise to memory B cells[18,19].

TABLE 3 Ability of antibodies to prevent cell death

a, Soluble CD40 antibody and anti-human immunoglobulin

Culture additive	% Viable cells (mean ± s.e.m. of 5 expts) recovered after: 16 h	40 h	72 h	96 h

anti-IgD	26 ± 8
anti-IgA	23 ± 3

a, The prevention of cell death in cultures of germinal-centre cells by the addition of soluble CD40 antibody and sheep red cells coated with anti-human immunoglobulin. *b*, The relative ability of antibodies against different human immunoglobulin classes to prevent cell death in isolated germinal-centre cells. The germinal-centre cells used in these experiments were isolated as described in Table 1. They were cultured and their viability assessed as described in Table 2. The anti-immunoglobulins (Ig) used and the method used for their conjugation to sheep red cells is specified in Table 1.

* CD40 antibody G28-5 was added to cultures at a final concentration of 5 μg ml^{-1} (ref. 7).

Defects in the selection system identified in this study could be involved in the pathogenesis of low-grade follicular lymphomas. These lymphomas have a (14; 18) translocation involving apposition of the proto-oncogene *bcl-2* and the immunoglobulin heavy-chain locus[20,21]. Vaux *et al.*[22] showed that expression of *bcl-2* transfected into IL-3-dependent cell lines prevented cell death on withdrawal of IL-3. The introduction of constructs representing the *bcl-2*-immunoglobulin gene fusion into the germ line of mice leads to the accumulation of mature B cells in the adult mice[23]. It is an intriguing possibility that the *bcl-2* gene product may be involved in overriding the apoptotic tendency of germinal-centre cells. □

T LYMPHOCYTES recognize antigens by means of T-cell receptors (TCR) composed of $\alpha\beta$ (refs 1–3) or $\gamma\delta$ heterodimers[4–6]. The mechanism governing the development of $\alpha\beta$- and $\gamma\delta$-bearing T cells from a common precursor T cell is so far unknown. It has been proposed that T-cell precursors rearrange their γ- and δ-chain genes first, and $\alpha\beta$ T cells are generated only from those cells that fail to rearrange productively both γ- and δ-chain genes[7,8]. Our recent study on $\gamma\delta$-transgenic mice contradicted this

hypothesis, however, and indicated that repression of γ-chain gene expression mediated by a transcriptional silencer element has a critical role in the generation of $\alpha\beta$ T cells[9]. Here we report that the generation of $\alpha\beta$ T cells is severely blocked in transgenic mice carrying γ- and δ-chain transgenes without the associated silencer, thereby strengthening the validity of the silencer model of T-cell development.

Our recent analysis of $\gamma\delta$-transgenic mice (called KN6 transgenic mice) constructed with relatively long (~40 kilobases (kb) each) $V_4J_1C_1\gamma$ and $V_5DJ_1C\delta$ genomic DNA clones indicated that, in contrast to the Pardoll-Allison model[7,8], introduction of productively rearranged γ- and δ-chain genes into the germline does not prevent the rearrangement of the endogenous α- and β-chain genes and their cell-surface expression[9]. In these transgenic mice, transcription of the γ-chain transgene is repressed in $\alpha\beta$ T cells apparently through a *cis*-acting DNA element (silencer) present in the flanking region(s) of the γ-chain gene. This led us to propose a model of T-cell development in which commitment of a given T-cell precursor to the $\alpha\beta$-lineage depends on the activation of the machinery acting on the silencer[9]. We have now constructed transgenic mice with γ- and δ-chain genes carrying no silencer element so as to perform the crucial test of the silencer model. The model predicts that the transgenes will be transcribed in all T cells in these mice, as opposed to the KN6 transgenic mice, and that their subsequent surface expression will prevent rearrangement and expression of TCR $\alpha\beta$-chain genes, in analogy to the immunoglobulin system[10].

As transgenes we used 15-kb and 21-kb genomic DNA fragments (Fig. 1) containing productively rearranged $V_5J_1C_1\gamma$ and $V_1D_2J_2C\delta$ genes, respectively, known to encode the $\gamma\delta$ TCR expressed on the surface of most early fetal thymocytes[11,12] and dendritic epidermal $\gamma\delta$ T cells (DEC)[11,13]. According to our previous study it is probable that the 15-kb γ-chain gene clone lacks the putative silencer element, because the transcription of a γ-chain transgene containing similar flanking regions is not repressed in $\alpha\beta$ T cells[9]. We analysed the progeny of two transgenic founders (henceforth called DEC transgenic mice).

Cell-surface expression of transgene-encoded TCR was investigated by flow cytometry, using monoclonal antibodies reactive with all $\gamma\delta$ TCR (3A10)[14] or $V_{\gamma5}$-encoded γ-chains only (F536)[11]. Consistent with previous reports, few if any $\gamma\delta$ T cells from nontransgenic adult mice expressed $V_{\gamma5}$-encoded $\gamma\delta$ TCR on their surface (Fig. 2*a*)[11,12]. By contrast, more than 95% of $\gamma\delta$ thymocytes or splenic T cells from the DEC transgenic mice were reactive with the F536 monoclonal antibody (Fig. 2*a*, and data not shown), indicating that, like the KN6 $\gamma\delta$ transgenic mice (Fig. 2*a* and ref. 9), the transgenes dominated the $\gamma\delta$ T cells for the expression of their TCR. The proportion of $\gamma\delta$ T cells in the thymus from DEC transgenic mice (25-75%) was dramatically increased in comparison with nontransgenic mice (0.5%) or KN6 transgenic mice (4.5%) (Fig. 2*a*). In addition, unlike KN6 transgenic mice, the thymus size was severely reduced in DEC transgenic mice (data not shown), suggesting that the generation of the main thymocyte subpopulation, that is, $\alpha\beta\text{TCR}^+$ cells, was strongly hampered in these animals.

This supposition was confirmed by immunofluorescence analysis using the anti-$\alpha\beta$TCR monoclonal antibody H57-597[15]; less than 3% of thymocytes from 7-day-old DEC transgenic mice were $\alpha\beta\text{TCR}^+$, whereas most (>60%) thymocytes from the age-matched control mice or KN6 transgenic mice carried $\alpha\beta$ TCR (Fig. 2*b*). The proportion of $\alpha\beta\text{TCR}^+$ thymocytes increased with age to reach 50% in 10-week-old mice (Fig. 2*b*). But because the total number of thymocytes was greatly reduced in the DEC transgenic mice, the absolute number of $\alpha\beta$ chain-bearing thymocytes never reached more than 5% of the level observed in nontransgenic mice (data not shown).

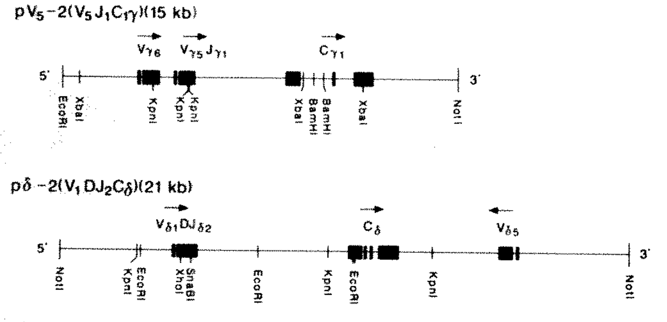

FIG. 1 Restriction maps of γ- and δ-chain genomic DNA clones used for the construction of transgenic mice. Filled boxes designate exons or gene segments; arrows above indicate transcriptional orientation.

METHODS. High-relative molecular mass DNA was isolated from a $\gamma\delta$ T-cell hybridoma KI-129[12] as previously described[22] and was used to construct a cosmid library using the plasmid pWe15 vector[23]. The library was screened with ^{32}P-labelled $V_{\gamma5}$, C_γ, $V_{\delta1}$ or C_δ probes for the cloning of the γ- and δ-chain genes. The C_γ and C_δ probes have been previously described[24,25]. Screening led to the isolation of clones pV5-2 and *p*δ-2, containing the entire γ- and δ-chain genes expressed by the KI-129 hybridoma. The junctional sequences of clones pV5-2 and *p*δ-2 were identical to those published[13,26]. The $V_{\gamma5}$ gene was assigned according to ref. 27. The $\gamma\delta$-transgenic mice were generated after injection into fertilized mouse eggs of purified pV5-2 and *p*δ-2 DNA as previously described[5,28].

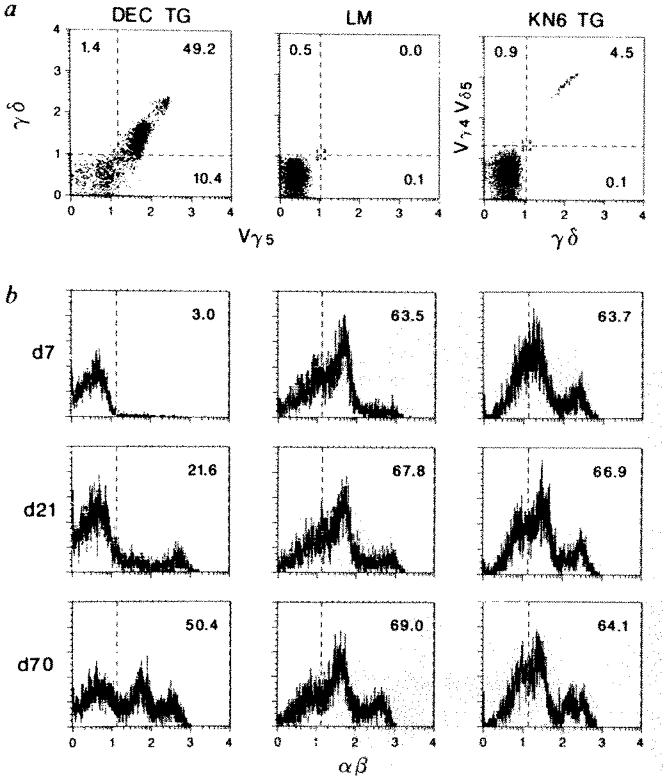

FIG. 2 Surface expression of $\gamma\delta$ and $\alpha\beta$ TCR by thymocytes from DEC transgenic, KN6 transgenic and nontransgenic mice. *a*, Thymocytes from 70-day-old DEC transgenic (left) and nontransgenic (middle) litter-mate mice were stained with anti-$V_{\gamma5}$ monoclonal antibody F536 followed by fluorescein isothiocyanate (FITC)-coupled goat anti-hamster IgG and with biotinylated anti-$\gamma\delta$-chain monoclonal antibody 3A10 followed by phycoerythrin-streptavidin. Shown are the dot-plot histograms (F536, horizontal axis; 3A10, vertical axis) obtained after flow cytometric analysis using a FACSCAN (Becton-Dickinson) and the percentage of cells in each quadrant. Fluorescence intensity is expressed in $\log_{10}$ units. For comparison is shown the dot-plot histogram (3A10, horizontal axis; 8D6 (anti-$V_{\gamma4}V_{\delta5}$)[14], vertical axis) of thymocytes from age-matched KN6 transgenic mice[9] (right). *b*, Thymocytes from 7-, 21- and 70-day-old DEC transgenic (left), nontransgenic (centre) and KN6 transgenic (right) mice were stained with biotinylated anti-$\alpha\beta$-chain monoclonal antibody H57-597 followed by phycoerythrin-streptavidin. The percentages of positive cells are indicated to the right of each histogram. Fluorescence intensity is expressed in $\log_{10}$ units.

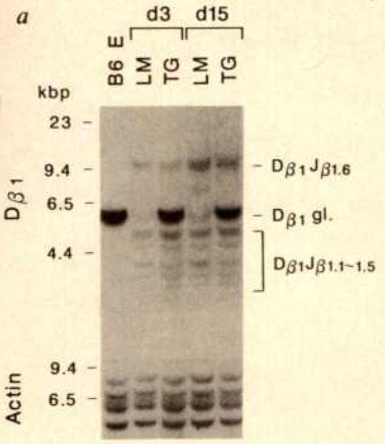

FIG. 3 Southern and northern blot analysis of DNA and RNA, respectively, from total thymocytes of DEC transgenic mice and nontransgenic littermates. *a*, Genomic DNA of thymocytes from 3- and 15-day-old DEC transgenic (TG) and nontransgenic (LM) mice and from C57BL/6 embryo (B/6 e) were digested with *Pvu*II, separated and transferred to nitrocellulose membrane. The Southern blot was hybridized with $D_{\beta 1}$ or actin probes. gl, Germ line DNA. DJ_β 1.1–1.6 bands were assigned according to ref. 29. *b*, RNA of thymocytes from 3- and 15-day-old DEC transgenic (TG) and nontransgenic (LM) mice was electrophoresed, transferred onto nitrocellulose membrane and hybridized to C_β or actin probes. The position of the 18S and 28S ribosomal RNA and that of $VDJC_\beta$ and DJC_β transcripts are indicated.

METHODS. Genomic DNA from thymocytes was purified as previously described[22], digested with *Pvu*II restriction endonuclease, separated (5 μg lane^{-1}) on a 0.6% agarose gel and transferred to GeneScreen Plus membrane (NEN) according to ref. 30. Hybridization with ^{32}P-labelled $D_{\beta 1}$ probe (*Pst*I fragment (1.06kb) from the clone encoding germ-line $D_{\beta 1}$ DNA[31]) and actin (*Pst*I fragment (0.8 kb) from a complementary DNA clone[32]) probes was carried out as previously described[30]. DNA probes were labelled by a random priming method[33]. The autoradiographic bands were detected and intensities quantitated using a FUJI Bioimage Analyzer BA100[34]. Total RNA was extracted using the guanidium thiocyanate–CsCl gradient method[35] and electrophoresed (10 μg lane^{-1}) through formaldehyde containing 1.2% agarose gel[22]. The RNA was transferred to GeneScreen Plus membrane and baked at 80 °C for 2 h. Northern blot hybridization with ^{32}P-labelled probes was performed under the same conditions as that of the Southern blot.

The above results indicate that introduction into the germ line of productively rearranged 'short', in contrast to 'long'[9], γ- and δ-chain transgenes severely hampers the development of αβ T cells. To further investigate the mechanism by which αβ T-cell differentiation is blocked, we analysed the DNA from thymocytes of young (3- and 15-day-old) DEC transgenic mice by the Southern blot method using a $D_{\beta 1}$ probe (Fig. 3*a*). In nontransgenic thymocytes, the germ-line $D_{\beta 1}$ band was barely detectable, reflecting the fact that incomplete *DJ* or complete *VDJ* rearrangements had taken place in most cells. By contrast, most $D_{\beta 1}$ gene segments remained in the germ-line configuration and the rest in the *DJ* state in the young transgenic mice (Fig. 3*a*). Consistent with the results of the Southern blot analysis, only low levels of full-size TCR β-chain messenger RNA (1.6 kb) were detected in transgenic thymocytes in comparison with nontransgenic thymocytes (Fig. 3*b*). Because *VJα* rearrangements were only partly inhibited in DEC transgenic mice (data not shown), these results strongly indicate that the primary mechanism by which the DEC γδ transgenes prevent αβ T-cell development is the blockage of complete *VDJβ* gene rearrangements. If this is indeed the case, why then do αβ T cells develop in older DEC transgenic mice? Northern blot analysis of αβ and γδ T-cell hybridomas from DEC transgenic mice shows that the levels of γ- and δ-chain transgene transcripts are lower in the former than in the latter (data not shown), suggesting that the level of γδ-TCR transcripts must be above a certain threshold to efficiently inhibit rearrangements of endogenous TCR genes. The αβ T cells observed in older DEC transgenic mice, then, are probably due to the accumulation of rare T cells in which the level of the transgene expression was below this threshold.

The drastic reduction in the number and the retardation of the appearance of αβ T cells in the DEC transgenic mice is perfectly consistent with the silencer model of T-cell development. The possibility must be considered, however, that αβ T cells are actually produced in these mice but are deleted in the thymus because of their coexpression of the transgene-encoded γδ TCR. Although nothing is known about the ligand specificity of the transgene ($V_5J_1C_1\gamma$ and $V_1D_2J_2C\delta$)-encoded TCR, it is conceivable that its expression in the αβ-cell lineage leads to negative selection of αβ T cells. To investigate this possibility, we crossed the DEC transgenic mice with αβ-transgenic mice[16]. If the silencer model is correct, then the introduction of functional α- and β-chain genes into DEC γδ-transgenic mice would be expected to restore αβ T cells. As shown in Fig. 4, ~80% of thymocytes from quadruple αβγδ-transgenic mice expressed αβ

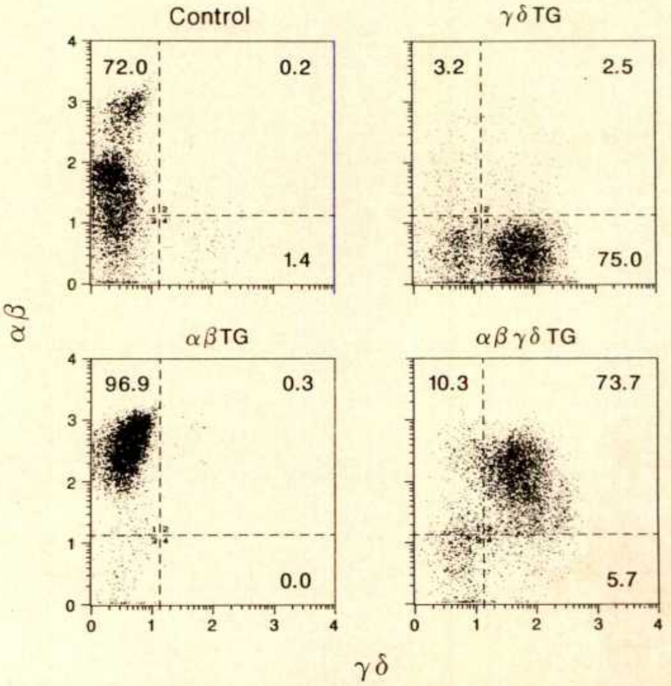

FIG. 4 Surface expression of γδ and αβ TCR by thymocytes from female γδ-, αβ- and αβγδ-transgenic mice. Thymocytes from 3-day-old DEC transgenic (γδ-TG), αβ-transgenic (αβ-TG), αβγδ-transgenic (αβγδ-TG) and nontransgenic (LM) mice were stained with FITC-coupled anti-γδ-chain monoclonal antibody 3A10 and biotinylated anti-αβ-chain monoclonal antibody H57-597 followed by phycoerythrin–streptavidin. The dot-plot histograms (3A10, horizontal axis; H57-597; vertical axis) obtained after cytofluorometric analysis are shown as well as the percentage of cells in each quadrant. Fluorescence intensity is expressed in $\log_{10}$ units.

METHODS. DEC transgenic females (H-2^b) were mated with αβ-transgenic male mice[16] (H-2^b) and their female progeny analysed 3 days after birth. Transgene expression was screened by staining thymocytes with anti-$V_{\beta 8}$ monoclonal antibody F23.1[36] and anti-αβ monoclonal antibody .57-597, or with anti-$V_{\gamma 5}$ monoclonal antibody F536 and anti-γδ monoclonal antibody 3A10. More than 95% of αβ T cells from αβ- and αβγδ-transgenic mice were $V^+_{\beta 8}$ and more than 98% of γδ T cells from γδ- and αβγδ-transgenic mice were $V^+_{\gamma 5}$.

TCR, whereas such cells were barely detectable in the thymus from DEC transgenic littermates. Furthermore, total numbers of $\alpha\beta$ thymocytes in $\alpha\beta$- and $\alpha\beta\gamma\delta$-transgenic mice were identical. Therefore we conclude that the drastic reduction in the number of $\alpha\beta$ T cells in the DEC transgenic mice is not due to intrathymic deletion of immature $\alpha\beta$ T cells.

Taken together, these observations strongly support the hypothesis that T-cell precursors are committed to generating $\alpha\beta$ T cells, independently of the rearrangement status of their γ-chain genes, and that this commitment involves activation of factor(s) that repress γ-chain gene transcription through interaction with a *cis*-regulatory element. Recently, Winoto and Baltimore[17] found that most extrachromosomal circular DNA generated by V_α-J_α joinings retain the δ-chain gene segments in the germ-line configuration and proposed that the control of δ-chain gene rearrangement plays a key part in the separation of $\alpha\beta$ and $\gamma\delta$ T-cell lineages. But, Takeshita *et al.*[18] reported that some 'α-circles' do contain rearranged δ-chain gene segments, suggesting that the control at the level of δ-chain gene rearrangement is insufficient.

It has previously been shown that, in contrast to C_1-associated γ-chain genes, $V_2J_2C_2\gamma$ genes are transcribed in $\alpha\beta$ T-cell clones and hybridomas[4,19-21]. The protein products of these genes have not been detected on the surface of freshly isolated T cells, however. Thus, the silencer model seems to apply to the separation of most, if not all, $\alpha\beta$ and $\gamma\delta$ T-cell lineages. □

SITE-SPECIFIC recombination requires conserved DNA sequences specific to each system, and system-specific proteins that recognize specific DNA sequences. The site-specific recombinases seem to fall into at least two families, based on their protein structure and chemistry of strand breakage (reviewed in ref. 1). One of these is the resolvase–invertase family, members of which seem to form a serine–phosphate linkage with DNA. Members of the other family, called the integrase family, contain a conserved tyrosine residue that forms a covalent linkage with the 3′-phosphate of DNA at the site of recombination. Structural comparison of integrases shows that these proteins share a highly conserved 40-residue motif[2]. *V-(D)-J* recombination of the immunoglobulin gene requires conserved recombination signal sequences (RS) of a heptamer CACTGTG and a T-rich nonamer GGTTTTTGT, which are separated by a spacer sequence of either 12 or 23 bases (reviewed in refs 3 and 4). We have recently purified, almost to homogeneity, a protein that specifically binds to the immunoglobulin J_κ RS containing the 23-base-pair spacer sequence[5]. By synthesizing probes on the basis of partial amino-acid sequences of the purified protein, we have now isolated and characterized the complementary DNA of this protein. The amino-acid sequence deduced from the cDNA sequence reveals that the J_κ RS-binding protein has a sequence similar to the 40-residue motif of integrases of phages, bacteria and yeast, indicating that this protein could be involved in *V-(D)-J* recombination as a recombinase.

The J_κ RS-binding protein was purified almost to homogeneity from the murine pre-B-cell line 38B9 (Fig. 1*a*) by the procedure of Hamaguchi *et al.*[5]. The J_κ RS-binding protein with a relative molecular mass (M_r) of 60,000 (60K) was expressed in lymphoid cell lines but not in nonlymphoid cell lines. The protein binds to the J_κ RS with a dissociation constant (K_d) of 1 nM. DNase-I footprinting analysis and the binding kinetic assay with several mutant probes strongly indicate that the protein directly interacts with the heptamer sequence and that a mutation in the heptamer greatly reduces the affinity of the J_κ RS-binding protein for DNA. Our initial attempt to determine the N-terminal amino-acid sequence was unsuccessful, probably because of modification of the N-terminal residue. The purified preparation was then digested with trypsin, and the resulting peptides were fractionated by reverse-phase HPLC (Fig. 1*b*). Twenty-three peptides were re-chromatographed and their amino-acid sequences were determined. Two oligodeoxyribonucleotide probes were synthesized on the basis of partial amino-acid sequences of the tryptic peptide 21 and used to screen a cDNA library derived from 38B9 poly(A)$^+$RNA (Fig. 2*a*, *b*). The probes hybridized with 2 of 1×10^6 colonies of the cDNA library. The two cDNA clones were purified and isolated by repeated screening. The clones designated as RBP-1 and RBP-2 contained 3.3- and 4-kilobase (kb) inserts, respectively. Restriction-site map-

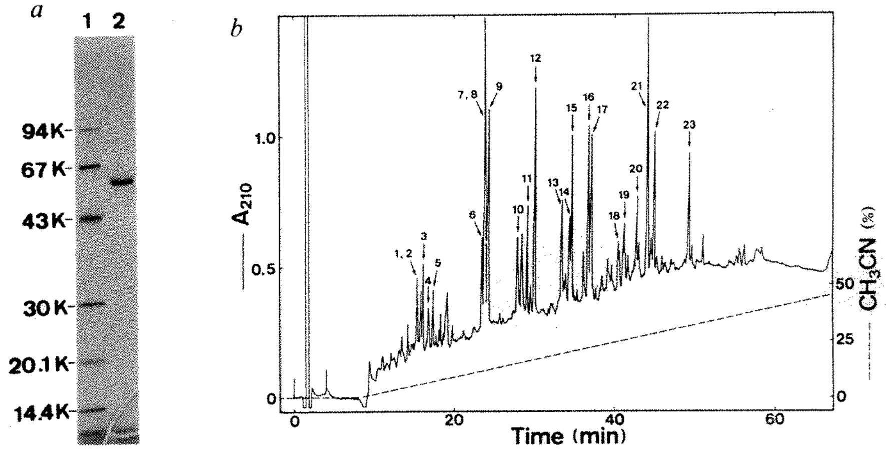

FIG. 1 Purification and partial amino-acid sequence analysis of J_κ RS-binding protein. *a*, Coomassie brilliant-blue stain of an SDS-polyacrylamide gel. Lane 1, mixtures of size markers; lane 2, purified J_κ RS-binding protein (0.5 μg). *b*, Reverse-phase HPLC of peptides formed by tryptic digestion of the purified J_κ RS-binding protein. Solid line and left-hand axis, absorbance at 210 nm (A210); broken line and right-hand axis, acetonitrile concentration. Peptides corresponding to peaks 1–23 were separated by re-chromatography and sequenced. All the amino-acid sequences thus determined agreed completely with regions of the amino-acid sequence deduced from the cDNA sequence (see Fig. 2*c*).

METHODS. A murine pre-B cell line 38B9 (ref. 13) which rearranges immunoglobulin genes during *in vitro* culture was maintained in RPMI 1640 medium with 10% (v/v) heat-inactivated FCS. The detailed protocol for the purification of the J_κ RS-binding protein is described in ref. 5. In brief, the crude nuclear extract from 38B9 (8×10^{10} cells) was fractionated by heparin-agarose column chromatography, followed by J_κ RS probe-coupled agarose column chromatography. Aliquots of fractions collected were assayed for binding activity to the J_κ RS probe in a gel-retardation assay. Each column chromatography was repeated twice. The method of SDS-PAGE was as in ref. 5. The dialysed preparation (200 pmol) of affinity-purified J_κ RS-binding protein were digested with trypsin. The digested peptides were fractionated by reverse-phase HPLC (Chemcosorb 30DS-H) with a linear gradient of acetonitrile in 0.1% trifluoroacetic acid. Each fraction was further separated by re-chromatography (μ-Bondaspher C-18 · 300A) to give a single absorbance peak. The amino-acid sequence of each peptide was determined using a gas-phase protein sequencer (Applied Biosystems).

FIG. 2 Nucleotide sequence and corresponding amino-acid sequence of J_κ RS-binding protein. *a*, Amino-acid sequence of tryptic fragment 21. Sequences used for construction of probes a and b are indicated. *b*, Synthetic oligodeoxyribonucleotide mixtures used as probes a and b. *c*, Nucleotide sequence and predicted amino-acid sequence (single-letter code) of J_κ RS-binding protein. Thick and thin underlines indicate peptide 21 and other peptides sequenced from the purified protein, respectively. Poly(A)-addition signal sequences are boxed. Asterisk indicates termination codon. The boundaries of the integrase motif region (Fig. 4) are indicated by two horizontal arrows.

METHODS. A cDNA library linked to the SV40 early promoter was constructed from poly(A)$^+$RNA of 38B9 cells, as described, by Okayama and Berg[14]. *E. coli* AG-1 transformants were screened with ^{32}P-labelled oligodeoxynucleotide probes a and b by the method of Hanahan and Meselson[15]. Nucleotide sequences were determined by the dideoxy method using plasmid pUC vector[16]. Oligonucleotides were synthesized by an automated synthesizer (Applied Biosystems).

ping and nucleotide sequence determination showed that the two clones are identical, except that RBP-2 has an extra 550-base-pair (bp) sequence at the 5′ end and uses the 140-bp downstream poly(A) addition site.

Nucleotide-sequence determination of the cDNA revealed an open reading frame that encodes 526 amino-acid residues (Fig. 2*c*). All the 23 partial amino-acid sequences determined (Fig. 1*b*) were identified in this amino-acid sequence deduced from the cDNA sequence. The calculated M_r of the J_κ RS-binding protein as 57K (including the initiating methionine), in reasonable agreement with the value of 60K estimated by SDS-PAGE. Of the total 4,000-bp insert, the 3′-noncoding region occupies 2,400 nucleotides excluding the poly(dA) tract; two polyadenylation signal sequences are located 30 and 170 nucleotides upstream of the poly(dA) tract of RBP-2. The size of the J_κ RS-binding protein messenger RNA (4.5 kb) of 38B9 cells,

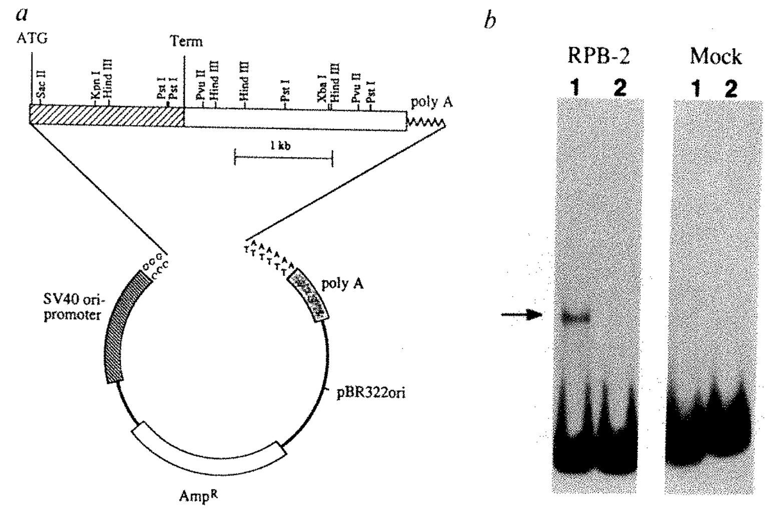

FIG. 3 *a*, Restriction map and structure of RBP-2 cDNA clone. The original RBP-2 clone in Okayama-Berg expression vector was used. Solid and zig-zag lines indicate vector and poly(A) tails, respectively. Black and open rectangles indicate coding and untranslated regions, respectively. *b*, Expression of RBP-2 cDNA in COS-7 cells. Nuclear extracts from RBP-2 and mock-transfected COS-7 cells were purified in a DNA-affinity column[5], and were assayed for binding to the J_κ RS probe (lane 1) or its single-base substitution mutant probe, J_κ 1P3 (lane 2) in a gel-retardation assay[5]. Term, termination site.

METHODS. COS-7 (1.5×10^7 cells) maintained in DMEM medium with 5% FCS were transfected and cultured as previously described[17]. After 48 h of culture, RBP-2 and mock-transfected COS-7 cells were collected. Their nuclear extracts were prepared and dialysed against buffer A (50 mM NaCl, 20 mM Tris-HCl buffer, pH 7.4, 1 mM EDTA, 1 mM DTT, 30% glycerol) as previously described[5]. Each nuclear extract was fractionated by affinity chromatography on a column containing 1 ml packed J_κ RS DNA-coupled agarose[5]. After sample application, the column was washed with five volumes of buffer A, and then eluted with buffer A containing 250 mM NaCl. For the gel-retardation assay, aliquots of eluted fractions containing the same amount of protein were incubated in reaction mixture (30 µl total), containing 50 mM NaCl, 5 mM Tris-HCl (pH 7.5), 1 mM EDTA, 1 mM DTT, 30% glycerol with 2 ng radiolabelled probe, 1 µg poly(dI), poly(dC) for 30 min at 20 °C. The incubated sample was analysed by 4% PAGE as previously described[5].

FIG. 4 Comparison of the 40-residue motif sequences of the J_κ RS-binding protein and recombinases of the integrase family (single-letter amino-acid code). *a*, Alignment with all the known sequences. *b*, Alignment with P4 integrase. Only residues that are conserved between the J_κ RS-binding protein (RBP-2) and any of the other proteins are boxed. Residues that belong to the same exchange groups with those of RBP-2 are shaded. Extents of conservations are indicated by closed and open symbols at the bottom, excluding and including, respectively, residues of the same exchange group. Circles, 100%, rectangles, >68%; triangles, >21%. Residues with less than two identical members but more than seven members of identical exchange groups are indicated by open hexagons. Residues that are conserved >60% among the other recombinases, but not conserved in RBP-2, are shown by crosses. Origins of integrase sequences are; Phages P2 (ref. 2), 186 (ref. 2), P22 (ref. 2), P1 (ref. 2), λ (ref. 2), φ80 (ref. 2), and P4 (ref. 18); FimE and FimB proteins (ref. 19); transposons Tn*2603* (ref. 20) and Tn*554* (ref. 21); plasmids pSB2 (ref. 22), pSR1 (ref. 23), pSB3 (ref. 24), pSM1 (ref. 22), and pKD1 (ref. 25); and Flp protein (ref. 26). Different reading frames for Tn*554* indicated by tnpA and tnpB.

estimated by northern-blot hybridization analysis, is in general agreement with the size of the RBP-2 encoded protein if the additional poly(A) tract is considered (data not shown).

To confirm that the cDNA clones isolated encode the J_κ RS-binding protein, COS-7 cells were transfected with RBP-2 cDNA in an expression plasmid linked to the simian virus 40 (SV40) early promoter (Fig. 3*a*). After 48 h of culture, the nuclear extract of transfected COS-7 cells was prepared and fractionated by affinity chromatography using agarose coupled to J_κ RS DNA[5]. Aliquots of fractions bound to the affinity column were assayed for binding to the J_κ RS probe in a gel-regardation assay. Binding was detected in the extract of RBP-2-transfected COS-7 cells but not in mock-transfected COS-7 cells (Fig. 3*b*). Furthermore, a marked reduction in the binding affinity was observed when a mutant probe (J_κ 1P3 probe) with a single base substitution of the third G in the heptamer was used (Fig. 3*b*), consistent with our previous observation that the GTG sequence of the heptamer interacts with the J_κ RS-binding protein[5]. These results strongly indicate that the RBP-2 cDNA sequence encodes the J_κ RS-binding protein. This protein has a basic residue cluster (Lys-Lys-Lys-Lys for residues 107–110) which often serves as a nuclear-localization sequence[6].

A computer survey did not reveal any other proteins that have extensive sequence homology with the overall sequence of the J_κ RS-binding protein. The protein does not seem to have any DNA-binding domains such as zinc-finger[7], helix-turn-helix[8], or leucine-zipper[9] structures. But the J_κ RS-binding protein contains a sequence similar to the 40-residue motif of the integrase family that includes λ phase integrase, fimbriae switch recombinase of *Escherichia coli* and yeast Flp recombinase[2] (Fig. 4*a*). In the 40-residue motif, three residues (His 1, Arg 4 and Tyr 38) are perfectly conserved among all the 18 integrase-family proteins so far sequenced. The conserved tyrosine residue (Tyr 38), of Flp[10,11] and λ phage integrase[12] is involved in the catalytic reaction of the integrase. The J_κ RS-binding protein conserves the His 1 and Tyr 38 residues, but not the Arg 4 residue. In addition, Leu 11 is >60% conserved among the other recombinases, but is not conserved in the J_κ RS-binding protein. Nonetheless, the J_κ RS-binding protein contains two highly (>68%) conserved residues (Gly 15 and His 40) and seven moderately (>21%) conserved residues within the 40-residue motif. If we regard residues in the same exchange group as conserved, 21 out of 40 residues of the motif region of the J_κ RS-binding protein are >32% conserved among all the 19 proteins.

Out of the other 18 recombinases, the J_κ RS-binding protein has the highest homology with the P4 integrase (Fig. 4*b*). The 40-residue motifs of these two proteins can be aligned without any deletions and insertions, and share 9 identical and 11 same-family residues. Furthermore, the first 16 residues of the recognition sequence (GAGTCCGGCCTTCGGCACCA) for the P4 integrase[18] has some homology with the sequence of the heptamer-nonamer of the immunoglobulin gene, that is, GAGTC(A)CGGTTTTTGT.

In view of the large evolutionary distance between bacteriophages and mouse, such homology indicates that this motif in the J_κ RS-binding protein could be conserved to maintain the function of the protein as a recombinase. It is of interest that the primary structures of recombinases of the integrase family are divergent except for this homologous 40-residue motif, which seems to be a catalytic domain but not a binding domain for DNA. *In vitro* studies of site-specific recombination indicate that the reaction is essentially catalysed by a single protein that seems to be required in stoichiometric rather than catalytic amounts, although additional accessory proteins are required in some cases[1]. Experiments are in progress to examine whether the J_κ RS-binding protein catalyses or stimulates *V*-(*D*)-*J* recombination, although other accessory binding proteins, such as integration host factor[1], could be required simultaneously for efficient recombination. □

Genetic evidence that *ZFY* is not the testis-determining factor

M. S. Palmer, A. H. Sinclair, P. Berta, N. A. Ellis, P. N. Goodfellow, N. E. Abbas* & M. Fellous*

Human Molecular Genetics, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, UK

IN mammals, the testis determining gene (*TDF*), present on the Y chromosome, induces the undifferentiated gonads to form testes[1]. The position of *TDF* on the human Y chromosome has been defined by analysing the genomes of XX males and XY females[2], generated by abnormal genetic exchange between the X and Y chromosomes in male meiosis[3]. In this way *TDF* has been localized close to the pseudoautosomal region shared by the sex chromosomes, in the distal Y-specific region. A recently cloned human gene, *ZFY*, has many features indicating that it is *TDF*[4–6]. For example, *ZFY* encodes a protein with many features of a transcription factor including a domain with multiple 'zinc-finger' motifs[4–6]. Less consistent with *ZFY* being *TDF*, however, is the presence of a very similar gene, *ZFX*, on the X chromosome[4,7], and the presence of a sequence related to *ZFY* on autosomes in marsupials[8]. We now report on analysis of XX males lacking *ZFY*. In these individuals, the male phenotype could be explained by a mutation in a gene 'downstream' of *ZFY* in the sex-determining hierarchy; but in that case there should be no exchange of material between the X and Y chromosomes. We find on the contrary that in 4 XX males lacking *ZFY*, there is exchange of Y-specific sequences next to the pseudoautosomal boundary, redefining the region in which *TDF* must lie.

By studying the sequences present in an XX male (LGL203) and absent in an XY female (WHT1013), Page *et al.* had previously localized *TDF* to within 140 kilobases (kb) (ref. 4 and Fig. 1). The latter patient, however, was not a typical exchange XY female, but had a translocation between the Y chromosome and chromosome 22. The sequences between the breakpoints in these patients were isolated and the gene *ZFY* was identified in this region.

FIG. 1 Map of distal short arm of Y chromosome: stippled region at left is the pseudoautosomal region. Cross-hatched region shows the position of *ZFY* identified by Page *et al.*[4]. The breakpoints in the XX male and XY female used in the localization of *ZFY* are shown. Individual probes used to define the breakpoints in the XX males reported here were isolated from overlapping clones obtained while walking along the Y chromosome[9], except probes 27a and GMGY3, which were isolated previously[15,16]. Hf0.2 derives from the pseudoautosomal region and is present on both X and Y chromosomes. The clones H2.1, P0.9, E1.3, 27a and GMGY3 are specific for the Y chromosome.

In previous reports we have described the isolation and structure of the boundary between the pseudoautosomal region and the sex chromosome-specific regions[9]. If *ZFY* is *TDF*, it should be predicted that all exchange XX males carry *ZFY*, whereas all XX males lacking *ZFY* are due to mutations elsewhere in the genome. The latter class cannot be derived by terminal X–Y exchange and should consequently lack the Y chromosome-derived pseudoautosomal boundary. Using a polymerase chain reaction (PCR)-based assay, 14 *ZFY*-negative XX males were screened for the presence of the Y chromosome-derived pseudoautosomal boundary: three XX males and one XX intersex individual were found to have the Y pseudoautosomal boundary (Fig. 2). Repeating these experiments by Southern blotting confirmed that all four sex-reversed individuals were positive for both the X and Y boundaries and were *ZFY*-negative (Fig. 3). The relative signal intensities between the X and Y boundary fragments excludes mosaicism and chimaerism as explanations of the results. The possibility that the boundary position is polymorphic is also unlikely as the boundary structure and position is invariant in more than 150 individuals tested; moreover, the Y boundary is in the same position in the great apes (ref. 9 and unpublished observations). The position of the exchanges in the four exceptional XX sex-reversed individuals was mapped by testing for reaction with a series of probes located between the boundary and *ZFY* (Fig. 3). The results summarized in Table 1 and in Fig. 1 show that all the breakpoints are clustered between the sequences defined by probes P0.9 and E1.3. The region of the Y chromosome present in these sex-reversed individuals does not include the region defined by Page *et al.*[4] as the sex-determining region. The simplest interpretation of these results is that *TDF* lies within 60 kb of the pseudoauto-

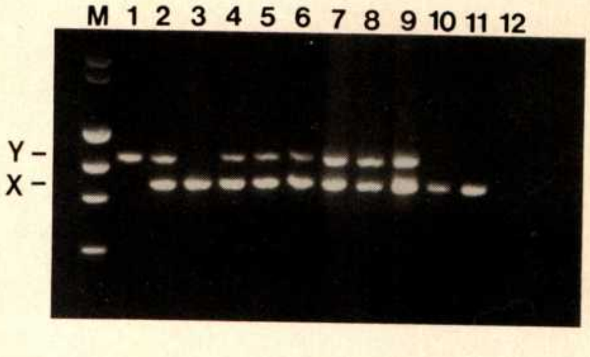

FIG. 2 PCR analysis of X and Y boundaries. Oligonucleotides specific for X- or Y-chromosomal sequences were used together with an oligonucleotide from the pseudoautosomal region as primers in PCR reactions[17]. The Y-specific fragment is 1.1 kb and the X-specific fragment, 0.95 kb. The size markers in lane M are 2.3- and 2.0-kb λ-*Hin*dIII fragments, and 1.35-, 1.0-, 0.87- and 0.60-kb ϕX173 *Hae*III fragments. PCR was performed on 1 μg genomic DNA from the following sources: (1) 3E7, a mouse–human hybrid containing the human Y chromosome as its sole contribution of human DNA[18]; (2) a normal XY male; (3) a normal XX female; (4) an XX male, SB, positive for *ZFY*; (5) an XX male J–JM positive for *ZFY*; (6) XX male, MB, negative for *ZFY*; (7) XX intersex, TL, negative for *ZFY*; (8) XX male, DL, brother of TL, negative for *ZFY*; (9) XX male, ZM, negative for *ZFY*; (10) XX male, PP, negative for *ZFY* and Y boundary; (11) XX male, LS, negative for *ZFY* and Y boundary; (12) no DNA added, control. Of fourteen *ZFY* XX males or intersex individuals analysed, four—MB, TL, DL, and ZM—were positive for the Y boundary, whereas the remainder—of which PP and LS are representative—were negative for the boundary. All XX males who had *ZFY* also had the Y boundary. Clinical details of the XX males will be published elsewhere[19].

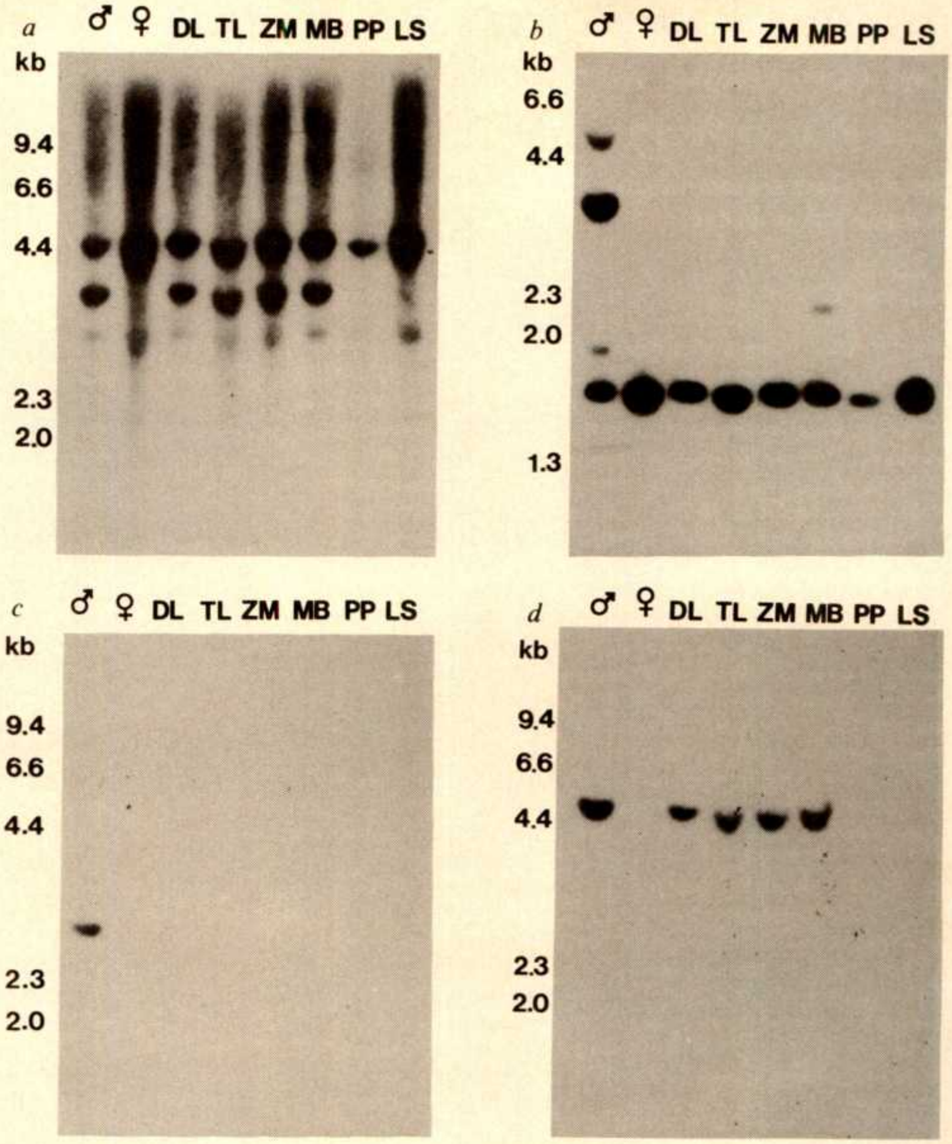

FIG. 3 Hybridization of probes to Southern blots. In each case filters contain the same lanes; ♂, normal male; ♀, normal female; DL, TL, ZM, MB, the four XX males discussed here, negative for *ZFY* but positive for the Y boundary; PP and LS, XX males negative for *ZFY* and the Y boundary. *a*, *Sac*I digests probed with Hf0.2—a pseudoautosomal probe[9]. *Sac*I gives a 4.5-kb X-specific fragment and a 3.2-kb Y-specific fragment across the pseudoautosomal boundary. *b*, *Eco*RI digests probed with a complementary DNA clone pMF-1, corresponding to a partial transcript of *ZFY* including the zinc-finger domain[6]. The three bands in the normal-male track not seen elsewhere are Y-specific. The weak 2.3-kb band seen in MB is probably due to a partial digestion and was not present in other digests of the same DNA sample in other experiments. *c*, *Hin*dIII digests probed with the Y-specific clone 27a[15]. Only the normal male was positive. *d*, *Eco*RI digests probed with the boundary proximal probe P0.9 (ref. 9). This probe is specific for the short arm of the Y chromosome.

somal boundary; this excludes *ZFY* as a candidate for *TDF*. These results also formally demonstrate that some XX males are not generated by terminal exchange and must be due to mutations elsewhere in the sex-determination pathway[10].

The only discrepancy between our results and those in previous publications is the description by Page *et al.*[4] of a female carrying a t(Y; 22) translocation which should include the Y pseudoautosomal boundary region. It is possible that this translocation is complex or, alternatively, *TDF* could have been inactivated by a position effect.

The four sex-reversed individuals vary in phenotype from normal male with testis, but lacking germ cells, to hermaphrodite with bilateral ovotestes and a uterus (Table 1). The variation in phenotype could be caused by the proximity of the breakpoints to *TDF*. Particularly striking are the two familial cases—the 'brother' and 'sister' TL and DL. Although the origin of these individuals is not clear, familial exchange XX males have been described previously[11], and one possibility is that the father has a mosaic gonad.

The results described here and by Koopman *et al.*[12] strongly argue against a role for *ZFY* in sex determination; *ZFY* could have a male specific function in spermatogenesis, however. Separate functions for *TDF* and *ZFY* have been proposed previously to explain the evolutionary relationship between the sex chromosomes of eutherians and metatherians[13], and could be consistent with the autosomal location of *ZFY*-related sequences in marsupials[8].

One explanation for the phenotypes we observe is that they result from the reciprocal breakpoints on the X chromosome. A more likely explanation is that the *TDF* gene lies close to, or even spans, the pseudoautosomal boundary. We are now testing these hypotheses. ☐

Zfy gene expression patterns are not compatible with a primary role in mouse sex determination

Peter Koopman, John Gubbay, Jérôme Collignon & Robin Lovell-Badge

Laboratory of Eukaryotic Molecular Genetics, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK

THE Y chromosome determines maleness in mammals. A Y chromosome-linked gene diverts the indifferent embryonic gonad from the default ovarian pathway in favour of testis differentiation, initiating male development[1,2]. Study of this basic developmental switch requires the isolation of the testis-determining gene, termed *TDF* in humans and *Tdy* in mice. *ZFY*, a candidate gene for *TDF*, potentially encodes a zinc-finger protein[3], and has two Y-linked homologues, *Zfy-1* and *Zfy-2*, in mice[4,5]. Although *ZFY*, *Zfy-1* and *Zfy-2* seem to map to the sex-determining regions of the human and mouse Y chromosomes, there is no direct evidence that these genes are involved in testis determination. We report here that *Zfy-1* but not *Zfy-2* is expressed in differentiating embryonic mouse testes. Neither gene, however, is expressed in W^e/W^e mutant embryonic testes which lack germ cells. These observations exclude both *Zfy-1* and *Zfy-2* as candidates for the mouse testis-determining gene.

The primordial gonads (genital ridges) of male and female mouse embryos are indistinguishable until ~11.5 days post coitum (d.p.c.). By 12.5 d.p.c., testis differentiation is apparent from the presence of cords formed by the alignment of Sertoli cells. It is expected that the gene responsible for testis determination will be expressed around this stage of development. *Zfy-1* or *Zfy-2* expression is not detectable by northern blot analysis of RNA from whole mouse embryos[6]. To enrich for gonadal tissue, we isolated fetal genital ridges and gonads and analysed their RNA by northern blotting. *Zfy* transcripts were detected in adult testis but not in fetal gonads (Fig. 1*a*). By contrast, the X-linked homologue *Zfx* (ref. 5) was expressed at all stages. *Zfy* gene expression is clearly associated with germ cells in adult testes because transcripts were undetectable in XX *Sxr* and XX *Sxr'* testes which lack germ cells[7,8] (Fig. 1*b*).

Because of the relative insensitivity of northern blotting, we used the sensitive polymerase chain reaction (PCR) technique to look for *Zfy* transcripts in dissected embryonic tissues (Fig 2). Whereas no transcripts were detected in 9.5 d.p.c. embryos increasing levels of *Zfy-1* expression were seen between 10.5 and 12.5 d.p.c.; *Zfy-1* expression was maintained for at least two further days in the testes. Transcripts were absent from male nongonadal tissues. DNA blot analysis of the PCR products confirmed the onset of *Zfy-1* expression at 10.5 d.p.c. (Fig. 2*a*). The minor signal detected in the 12.5 d.p.c. ovary sample must reflect the occasional error in sexing embryos at this stage by gonadal morphology, given that RNA was derived from large numbers of pooled embryo samples. When RNA was prepared from genital ridges and gonads from individual embryos without pooling, a similar profile of *Zfy-1* expression between 10.5 and 14.5 d.p.c. was seen (Fig. 2*b*). In addition, decreasing levels of expression were found between 14.5 and 17.5 d.p.c.; all female samples were negative for *Zfy-1* expression.

By contrast, *Zfy-2* transcripts were detected in adult testes but not in embryonic mouse gonads at any of the stages examined (Fig. 2*a*). We conclude from this that *Zfy-2* is not *Tdy*.

The oligonucleotide primers used to detect *Zfy* transcripts were expected to give single PCR products of 477 base pairs (bp), based on published complementary DNA sequences[6,9]. Instead, two additional products of ~520 and 570 bp were detected (Fig. 2*b*). Sequencing of DNA from each band from 12.5-d.p.c. testes revealed three alternatively spliced *Zfy-1* transcripts (Fig. 3). No stage-specific difference in their relative abundance was seen. There is no obvious significance to this alternative splicing, which is within the 5′ untranslated portion of the messenger RNA. The additional exons in the longer *Zfy-1* transcripts do not introduce any alternative translational start sites associated with open reading frames, and would not alter the *Zfy-1* protein.

The embryonic gonad has both somatic and germ cell components, but it is clear that germ cells are not required for testis determination or differentiation[10,11]. The *W* mutation in mice affects primordial germ cell proliferation and migration into the genital ridge[12]; in embryos homozygous for the most severe form, W^e, testes form normally despite being virtually devoid of germ cells (ref. 13; and M. Buehr, personal communication).

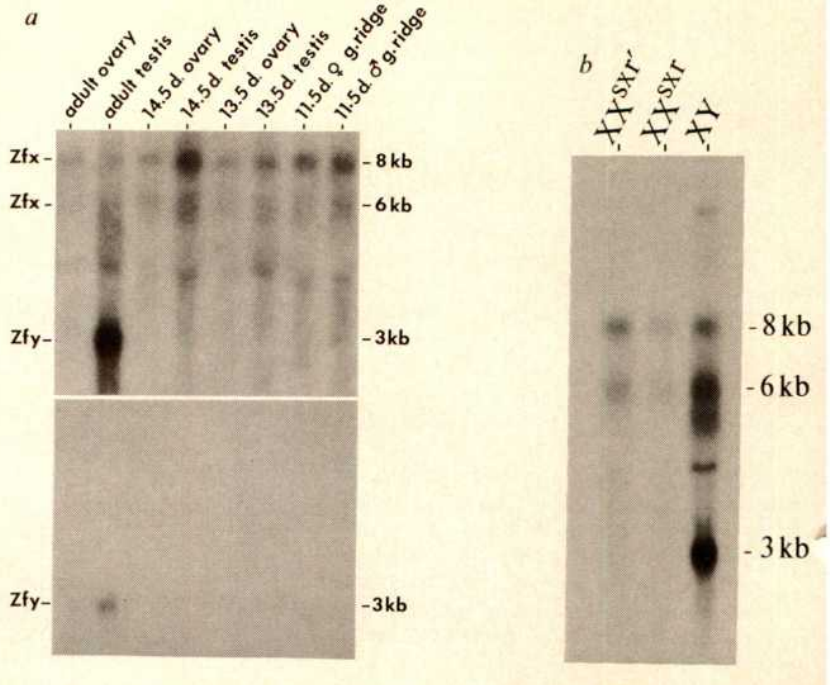

FIG. 1 Northern blot analysis of *Zfy* gene expression. *a*, Analysis of RNA from adult and embryonic mouse gonads and urogenital ridges (g. ridge) shows expression of a 3-kilobase (kb) *Zfy* transcript specific to adult testis. The upper panel shows hybridization to a 1.9-kb *Hin*dIII *Zfy-1* genomic fragment containing the zinc-finger encoding exon, which also detects 6- and 8-kb *Zfx* transcripts. The lower panel shows the same filter rehybridized with the first 800 bp of a *Zfy-1* cDNA[9] which is specific for *Zfy* sequences. *b*, Absence of the 3-kb *Zfy* transcript in XX *Sxr* and XX *Sxr'* adult testes which lack germ cells. The 'zinc-finger' probe described above shows that *Zfx* transcripts are present in both testis types as well as in normal XY testes.

METHODS. Total RNA (10 μg) was electrophoresed on formaldehyde-agarose and transferred to Hybond-N filters (Amersham). Filters were hybridized to ^{32}P-labelled random-primed DNA probes, then washed in 0.1 × SSC-0.1% SDS at 50 °C for 1 h and exposed to X-ray film for 1-3 days. Parkes outbred mice were used for all experiments unless otherwise stated. The day of vaginal plug was taken to be 0.5 d.p.c. Embryos 9.5-11.5 d.p.c. were sexed by staining for sex chromatin in amnion cells[17], and thereafter by gonadal morphology.

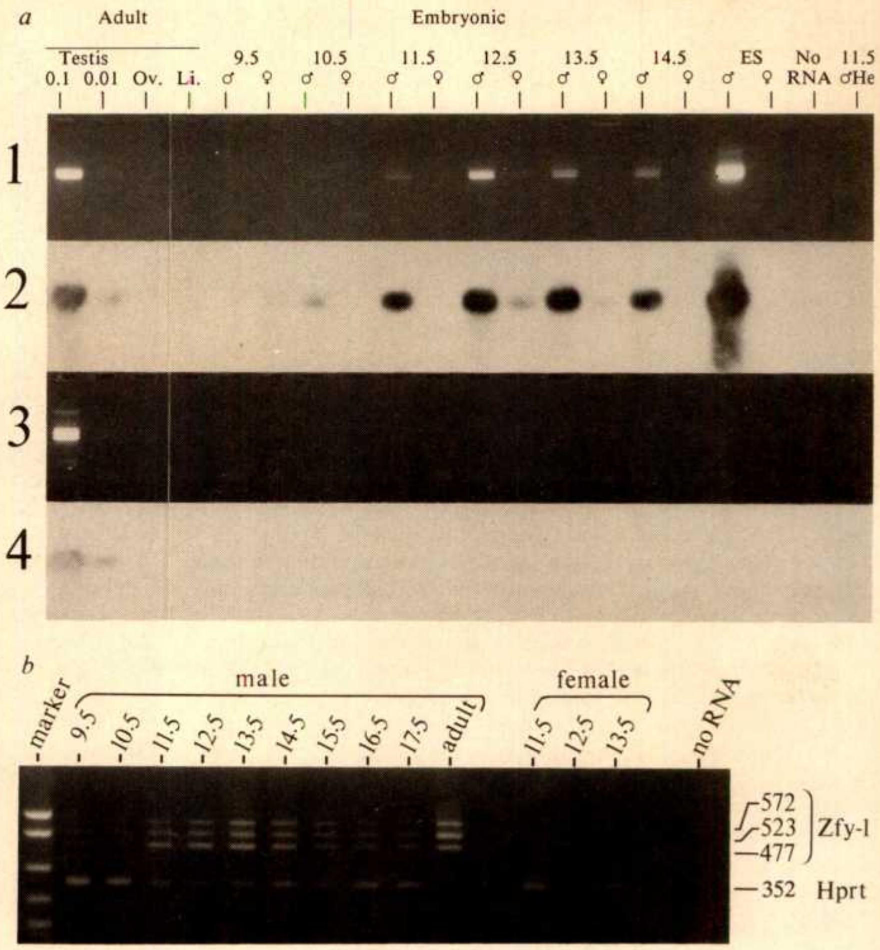

FIG. 2 PCR analysis of *Zfy-1* and *Zfy-2* expression in embryonic mouse gonads. *a*, Bands correspond to *Zfy-1* and *Zfy-2* transcripts in RNA derived from tissue pooled from up to 200 embryos or adults. Rows 1 and 3: ethidium bromide-stained agarose gels showing PCR products obtained using primers specific for *Zfy-1* and *Zfy-2*, respectively. Rows 2 and 4: corresponding Southern blots hybridized with the *Zfy*-specific probe described in Fig. 1 legend. These gels did not allow resolution of the three separate bands associated with *Zfy* expression (see below and Fig. 3). *b*, PCR analysis using RNA prepared from individual embryos or from adult testis. Ethidium bromide-stained agarose gel showing three PCR products obtained using *Zfy-1*-specific primers; specific primers for hypoxanthine phophoribosyl transferase (Hprt) transcripts were included as a positive control for each sample. Band sizes are shown in base pairs. Abbreviations: Ov, adult ovary; Li, adult male liver; 9.5, 9.5-d.p.c. embryos posterior to forelimb bud; 10.5, 10.5-d.p.c. embryos between forelimb and hindlimb buds; 11.5, 11.5-d.p.c. urogenital ridges; 12.5–17.5, 12.5–17.5-d.p.c. fetal gonads; ES, embryonic stem cells, either CCE[18] (♂) or A13[19] (♀); No RNA, water added to reverse transcription reactions in place of RNA solution; 11.5♂He, heads of 11.5-d.p.c. male embryos; Marker, pBR322/*Msp*I fragments (622, 527, 404, 309 and 242 bp).

METHODS. *a*, Total RNA (1 μg; 0.1 or 0.01 μg from adult testis) was reverse transcribed in 30 μl as described in ref. 5, at 42 °C for 30 min. Of this, 5 μl was added to a 50-μl PCR reaction containing 0.05% Nonidet P-40, 1.5 mM each dNTP, 500 ng each 'outer' primer, and 2.5 U *Taq* polymerase in the supplied buffer (Anglian Biotec). DNA was amplified by 20 cycles of 94 °C for 5 s, 65 °C for 30 s, and 72 °C for 30 s in a Techne PHC-2. From each reaction, 1 μl was transferred to a new reaction containing 'nested' primers and amplified a further 20 cycles. A 5 μl aliquot was electrophoresed on a 2% agarose–TBE gel. *b*, Small-scale RNA preparations were made using the AGPC method[20]. The amount of RNA reverse-transcribed corresponded to 100% of 9.5 and 10.5-d.p.c. tissue, 100% of a single 11.5-d.p.c. urogenital ridge or 12.5-d.p.c. gonad, 40%, 20%, 12.5%, 9%, and 7.6% of single testes from 13.5 to 17.5 d.p.c., respectively, 50% of a 13.5-d.p.c. ovary, and 0.5% of an adult testis. These proportions were intended to reflect gonadal volume. In each case the entire 7.5-μl reverse transcription reaction was amplified as above, with the addition of 500 ng of each *Hprt* primer to the first PCR reaction; 20 μl of the second reaction was electrophoresed. Primer sequences (5′–3′) were as follows. *Zfy-1* outer primers were (5′) GTTAC TCATT TTCAG GTGTT CTGGG and (3′) GTGTC AGCTG TTATA GGATC AGTGA; *Zfy-2* outer primers were (5′) CCTGT TGTTG CTGTT GTGGT TCTCG and (3′) ATGTC GGCTG TCAAA GGATC AGTGG. These primers were from corresponding regions of the *Zfy-1* and *-2* cDNAs[6,9]. Nested primers are described in Fig. 3 legend. *Hprt* primers were (5′) CCTGC TGGAT TACAT TAAAG CACTG and (3′) GTCAA GGGCA TATCC AACAA CAAAC from exons 3 and 8 of the mouse gene, respectively[21].

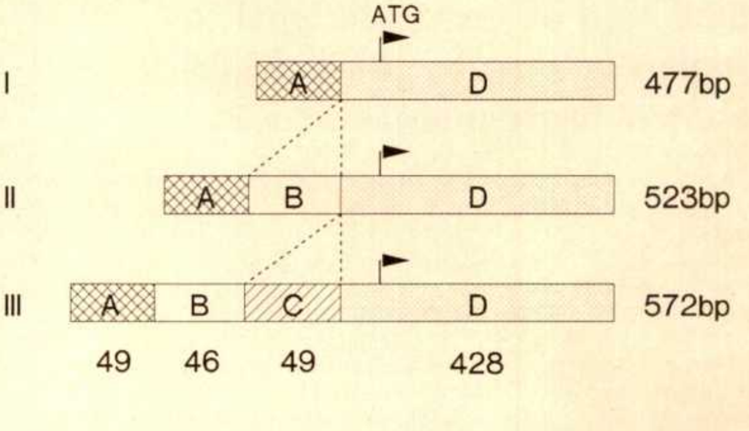

FIG. 3 Alternative splicing of *Zfy-1* transcripts. The composition of the three different PCR products obtained from 12.5-d.p.c. testis RNA with the *Zfy-1* primers was deduced from DNA sequencing. The nucleotide sequence and size of each block is shown; the translation initiation codon ATG is indicated in block D. Transcript I corresponds to the published *Zfy-1* cDNA sequence[9], except for the single base difference shown in lower case, presumably a polymorphism between the *Mus musculus musculus* and *M. m. domesticus* subspecies. Transcripts II and III contain the additional exons B and C.

METHODS. PCR as described in Fig. 2 legend; nested primer sequences are shown underlined. DNA from each gel band was cloned into Bluescript (Stratagene) and six clones of each type sequenced using Sequenase (USB).

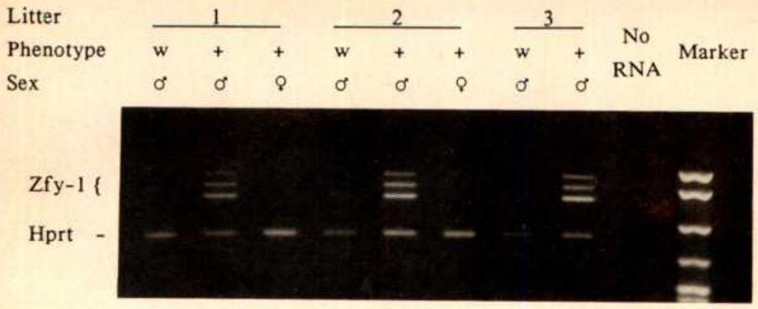

FIG. 4 Lack of *Zfy-1* expression in W^e/W^e fetal testes. The three bands corresponding to *Zfy-1* expression were detectec using RNA from phenotypically wild-type (+) male fetal testes but not phenotypically mutant (w) testes. The control *Hpr* band was detected in all samples. Littermates from three separate litters were analysed.

METHODS. Random-bred C3H/H-101 W^e/+ mice were matec and the progeny scored as homozygous mutants by liver morphology at 14.5 d.p.c., (ref. 22) and sexed by gonad morphology. Small-scale RNA preparations were made and analysed as described in Fig. 2 legend. In the first round of the PCR, 50% of the RNA yield from each single gonad was used.

Further, data from XX↔XY chimaeras implies that *Tdy* must act cell-autonomously in the somatic supporting cell lineage of the genital ridge[14]. If *Zfy-1* is indeed *Tdy*, expected transcripts of *Zfy-1* should be found in the somatic portion of the developing testis.

To test this, we analysed embryos homozygous for the W^e mutation. Their testes lacked *Zfy-1* transcripts (Fig. 4), demonstrating that *Zfy-1* expression in normal testes is due to the presence of germ cells. An alternative pair of PCR primers, from the exons encoding the putative nuclear localization signal and the 'zinc-finger' motifs[6,9], confirmed the absence of *Zfy-1* and *Zfy-2* transcripts in W^e/W^e fetal testes (data not shown). The formation of testes in the absence of *Zfy* expression, and the association of *Zfy-1* expression with germ cells, argues that *Zfy-1* is not *Tdy*.

ZFY was initially regarded as a candidate for *TDF* by virtue of its location on the Y chromosome and because its putative product is consistent with cell-autonomous action. Several more recent observations have compromised this view. First, theories of sex determination involving *ZFY*-like genes must take into account the presence of an X-linked homologue in many species and an additional autosomal homologue in mice[3,5]. Second, *ZFY*-like sequences are not found on the sex chromosomes of marsupials, which seem also to have a Y-dependent sex-determining mechanism[15]. Third, *Zfy-1* and *Zfy-2* appear to be expressed normally in a line of mice shown genetically to be mutant in *Tdy* (R.L.-B *et al.*, manuscript in preparation). Fourth, XX male patients have been described who possess Y-linked sequences but not *ZFY*[16]. Finally, the sites of expression of *Zfy-1* and *Zfy-2* indicate that neither is *Tdy*, and that both may instead have a role in male germ cell development. □

MEMBRANE transport between the endoplasmic reticulum and the plasma membrane, which involves the budding and fusion of carrier vesicles, is inhibited during mitosis in animal cells[1–5]. At the same time, the Golgi complex[6] and the nuclear envelope[7], as well as the endoplasmic reticulum in some cell types, become fragmented. Fragmentation of the Golgi is believed to facilitate its equal partitioning between daughter cells[8]. In fact, it has been postulated that both the inhibition of membrane traffic and Golgi fragmentation during mitosis are due to an inhibition of vesicle fusion, while vesicle budding continues[8]. Although less is known about the endocytic pathway, internalization[9–11] and receptor recycling[12,13] are also arrested during mitosis. We have now used a cell-free assay to show that the fusion of endocytic vesicles from baby hamster kidney cells is reduced in *Xenopus* mitotic cytosol when compared with interphase cytosol. We reconstituted this inhibition in interphase cytosol by adding a preparation enriched in the starfish homologue of the cdc2 protein kinase. Inhibition was ≥90% when the added cdc2 activity was in the range estimated for that in mitotic *Xenopus* eggs, which indicates that during mitosis the cdc2 kinase mediates an inhibition of endocytic vesicle fusion, and possibly other fusion events in membrane traffic.

To study the regulation of membrane traffic in mitotic cells, we used a cell-free assay that reconstitutes the fusion of early endocytic vesicles. In interphase cells, this fusion apparently reflects lateral interactions between early endosomal elements (for a review, see ref. 14). This fusion may also share an *N*-ethylmaleimide-sensitive factor[15] and the involvement of GTP-binding proteins[16] with vesicular transport in the secretory pathway[17–19].

As in our previous studies[20], the early endocytic vesicles of two baby hamster kidney (BHK) cell populations were labelled separately with avidin and biotinylated horseradish peroxidase (bHRP) by fluid-phase endocytosis for 5 min at 37 °C. Cytosol-free endosomal fractions were then prepared from each cell population, mixed in the fusion assay with cytosol and incubated

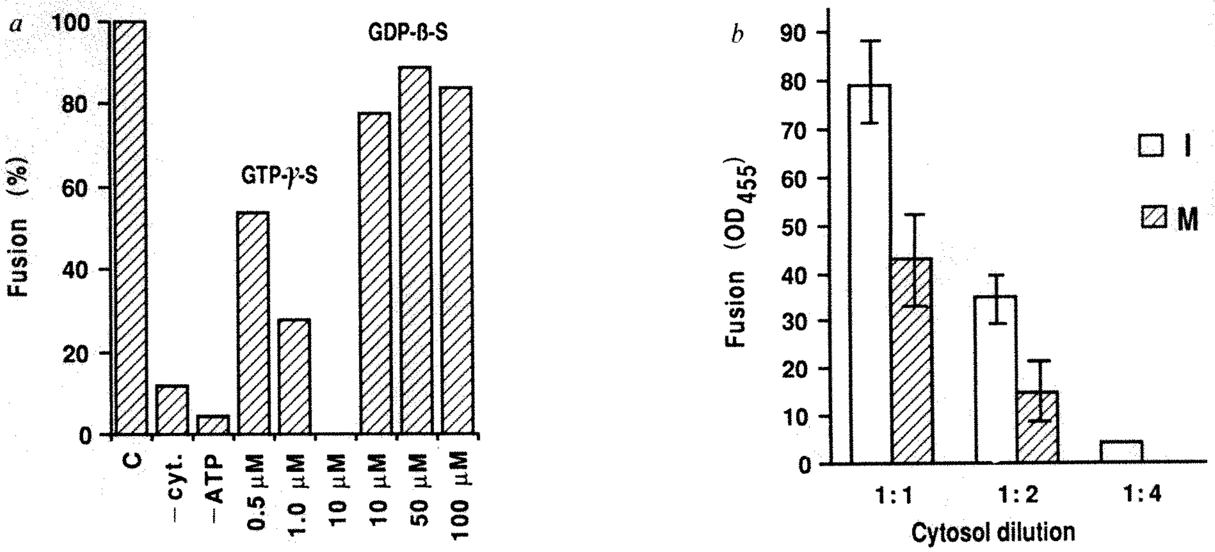

FIG. 1 Early endocytic vesicle fusion reconstituted in *Xenopus* interphase and mitotic cytosols. *a*, To compare different experiments, fusion is expressed as a percentage of the control value. C, control; −cyt., without cytosol; −ATP, without ATP. Concentrations of GTP-γ-S and GDP-β-S as indicated.

METHODS. BHK cells from 15×75-cm^2 dishes were released with trypsin, diluted three times with ice-cold PBS containing 5 mg ml^{-1} BSA (PBS-BSA), centrifuged at 750*g* for 5 min and washed a further three times in ice-cold PBS-BSA. The cells were then incubated for 5 min at 37 °C with 3.3 mg ml^{-1} avidin or 1.7 mg ml^{-1} bHRP in medium[20] and washed three times by centrifugation as above. The cells were subsequently resuspended in 10 ml sucrose (0.25 M), 3 mM imidazole pH 7.4 (HB), centrifuged, resuspended in 1 ml HB and homogenized in a tight-fitting Dounce. A post-nuclear supernatant was prepared by centrifugation at 1500*g* for 15 min, made up to a concentration of 40.6% sucrose, 0.5 mM EDTA in 3 mM imidazole pH 7.4, and loaded in 0.4-ml aliquots at the bottom of a Beckman polycarbonate 11×34-mm tube. The tube was then filled sequentially with a cushion of 0.6 ml sucrose (35%), 3 mM imidazole pH 7.4, 0.5 mM EDTA and 0.3 ml HB, 0.5 mM EDTA. The avidin- (or bHRP-) containing early endocytic vesicles were floated to the 35% sucrose-HB interface by centrifugation for 45 min at 100,000*g* in a table-top TL-100 ultracentrifuge, using a TLS-55 rotor. The interface fraction was collected with a pump, frozen in 25-μg aliquots in liquid nitrogen and stored until use. Concentrated *Xenopus* interphase and mitotic extracts were prepared as in ref. 25, and contained ~40 mg protein per ml. In the fusion assay, 25 μg of each fraction (avidin and bHRP) were mixed on ice with 50 μl cytosol (~2 mg protein). The volume of the reaction was 150 μl and the mixture contained 50 mM potassium acetate, 12.5 mM HEPES buffer, 1 mM magnesium acetate, 1.5 mM dethiothreitol (DTT), 1 μg ml^{-1} cytochalasin D and an ATP-regenerating or -depleting system as described in ref. 20. The fusion reaction was carried out for 45 min at 37 °C in the presence of biotinylated insulin, the samples were then returned to ice-temperature, excess biotinylated insulin added and the samples extracted in detergents[20]. The fusion-specific complex (avidin-bHRP) was quantitated with ELISA by measuring the enzymatic activity of bHRP at 455 nm (ref. 20). For *b*, The experiment was as for *a*, except that 50 μl (1:1), 25 μl (1:2) and 12.5 μl (1:4) interphase (I) and mitotic (M) extracts were added to the reaction mixture, which was adjusted to 150 μl, and to the same concentration of reagents as in Fig. 1*a*. The enzymatic activities of bHRP (optical density (OD) at 455 nm $\times10^3$) complexed to avidin are indicated for the different extracts.

in vitro for 45 min at 37 °C. During the *in vitro* reaction, fusion between avidin- and bHRP-containing endocytic vesicles resulted in the formation of an avidin-bHRP complex. At the end of the reaction, the mixture was extracted in detergents in the presence of excess biotinylated insulin to quench the uncomplexed avidin, and the amount of avidin-bHRP formed was quantitated with enzyme-linked immunosorbent assay (ELISA)[20,21]. In the studies described here, it was important to use a well-characterized source of mitotic and interphase cytosols. Concentrated extracts (~40 mg per ml protein) were prepared by high-speed centrifugation of *Xenopus* eggs that were either arrested in metaphase II[22] or activated by an electric shock[23]. The mitotic status of the extracts was estimated by measuring H1 histone kinase activity, and corresponded to 0.5–1.0 pmol of phosphate transferred from ATP to H1 histones min^{-1} μl^{-1} and >8.0 pmol of phosphate transferred from ATP to H1 histones min^{-1} μl^{-1} for interphase and mitotic extracts, respectively. These activities were expected to reflect the cytosolic values *in vivo*[24], because the extracts were prepared after a minimal dilution of the egg volume (30% v/v dilution). Fusion of BHK endocytic vesicles could be reconstituted in interphase *Xenopus* cytosol and, as expected, required cytosol as well as ATP (Fig. 1*a*). The extent of fusion depended on the concentration of added cytosol (Fig. 1*b*). Specificity of the fusion reaction was shown by its inhibition at low GTP-γ-S concentrations (Fig. 1*a*). This observation and others[16] indicate that GTP-binding proteins may be involved in controlling endocytic

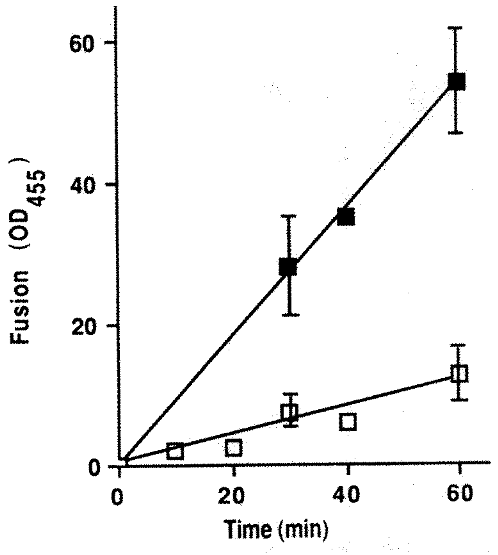

FIG. 2 Time course of the fusion with (□) or without (interphase control, ■) cdc2 kinase. The experiment was as in Fig. 1*a*, except that 1 μl cdc2 kinase prepared as in ref. 24 up to the phosphocellulose step, was added to each fraction and to an aliquot of interphase cytosol. For maximal inhibition, each fraction and the cytosol were pre-incubated separately for 15 min at 22 °C in the presence of cdc2 kinase, mixed and then further incubated at 37 °C for the indicated times to allow fusion to proceed. Fusion was measured by bHRP activity at OD_{455} and is indicated as in Fig. 1*b*.

vesicle fusion. By contrast, high concentrations of GDP-β-S had little effect.

When the assay was carried out in the presence of mitotic cytosol, the fusion activity was reduced (Fig. 1*b*) and the inhibition observed with different extracts paralleled the H1 histone kinase activities measured during the reaction (see below). This prompted us to test purified preparations of the kinase in the fusion assay. In mitotic *Xenopus* extracts, most of the H1 histone kinase activity is due to the homologue of the fission yeast $p34^{cdc2}$ and the cdc2 kinase from mitotic yeast phosphorylates H1 histones[26]. The role of the cdc2 kinase in controlling the interphase-mitosis transition in yeast, as in animal cells, is now well established[27,28]. Using *in vitro* assays, the maturation promoting factor (MPF), which has cdc2 activity, was shown to mediate nuclear envelope breakdown[29-31], chromosome condensation and spindle assembly[30,31].

Partially purified preparations of cdc2 kinase were obtained from starfish with high activities corresponding to the transfer from ATP to H1 histone of ~800 pmol phosphate per min per µl extract. These cdc2 kinase preparations were used to complement the fusion assay in the presence of interphase cytosol. In the absence of cdc2 kinase, fusion increased linearly with the time of the reaction (Fig. 2). When the cdc2 kinase was added at an activity corresponding to 4-5 pmol phosphate transferred per min per µl reaction mixture, a 75% reduction in the extent of fusion was observed for up to 60 min. Activity of the cdc2 kinase in the assay was also tested using gel electrophoresis and autoradiography by following the phosphorylation of endogenous substrates present in the reaction mixture after 5-min pulses of $[^{32}\mathrm{P}]$ATP (data not shown).

To establish the relationship between the cdc2 kinase activity and the inhibition of fusion, the assay was performed in the presence of increasing amounts of cdc2 kinase (Fig. 3). This titration correlated well with individual observations made with two different preparations of the cdc2 kinase (Fig. 3). Moreover, the inhibitions observed with mitotic cytosols (see Fig. 1*b*) were well within the range expected from the H1 histone kinase activities of the corresponding reaction mixtures (Fig. 3). This correlation strongly indicates that inhibition of fusion was mediated by the cdc2 kinase. Fusion activity rapidly decreased as the kinase activity became greater than that corresponding to the transfer of 1.0 pmol phosphate to H1 histones per min per µl reaction mixture. Half-maximal inhibition was observed at an activity corresponding to the transfer of 2.3 pmol phosphate per min per µl reaction mixture, and fusion was essentially abolished at activities corresponding to the transfer of ≥10 pmol phosphate per min per µl reaction mixture. Because the kinase activity of the cytosol in mitotic *Xenopus* eggs is estimated to be in this latter range, early endocytic vesicle fusion *in vivo* is probably efficiently arrested during mitosis.

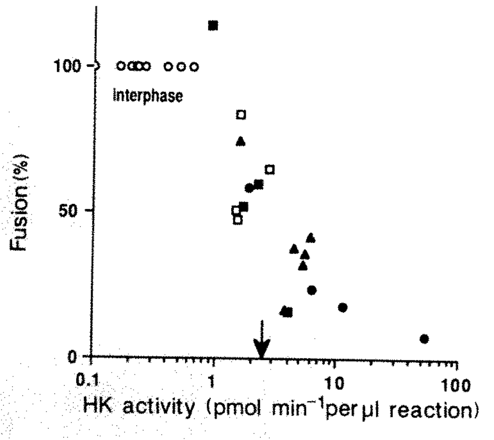

FIG. 3 Titration of fusion at increasing cdc2 kinase activity. Fusion activity is expressed as a percentage of the interphase value so that comparison between different experiments can be made. Titration of the fusion at increasing cdc2 activity (●) is compared with individual experiments carried out with two preparations of cdc2 kinase as in Fig. 2 (■, ▲). □, Assays using mitotic extracts as in Fig. 1*b*. The H1 histone kinase (HK) activities of the latter reaction mixtures were lower than those of the original mitotic extracts partly because the extracts were diluted three times in the final volume of the reaction (see Fig. 1*a*). The HK activity was measured as in ref. 25.

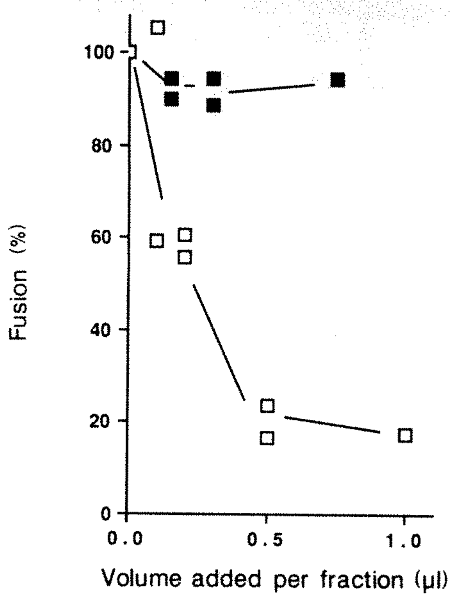

FIG. 4 Depletion of $p34^{cdc2}$ with $p13^{suc1}$ beads. The experiments were carried out as in Fig. 3 after adding the indicated volumes of the cdc2 preparation before (□) or after (■) $p34^{cdc2}$ depletion. Specific and quantitative depletion of the $p34^{cdc2}$ was carried out by affinity chromatography using $p13^{suc1}$ as a ligand[34]. The $p34^{cdc2}$-depleted preparations were used in the assay at the same protein concentration as the original $p34^{cdc2}$-containing preparations.

To demonstrate further that fusion inhibition was caused by the cdc2 kinase, the purified starfish preparation was depleted of $p34^{cdc2}$ by affinity-binding to the product of the fission yeast *suc1*⁺, gene $p13^{suc1}$, coupled to agarose beads. Depletion was efficient and specific, as monitored by H1 histone kinase activity and western blotting with an antibody against the highly conserved PSTAIR amino-acid sequence of $p34^{cdc2}$ (data not shown). The association of $p34^{cdc2}$ with $p13^{suc1}$ (refs 32, 33) has been used to retrieve $p34^{cdc2}$ (refs 34-36). Figure 4 shows that fusion was not inhibited after $p34^{cdc2}$ depletion. Finally, $p34^{cdc2}$ retained on $p13^{suc1}$ beads could be eluted with excess $p13^{suc1}$ and further purified by an additional chromatography step on a mono-S column in a 1:1 stoichiometric complex between $p34^{cdc2}$ and cyclin B (ref. 34). After addition of affinity-purified $p34^{cdc2}$, a 40% inhibition was observed when the histone kinase activity measured in the assay corresponded to the transfer of 1.5 pmol phosphate per min per µl. These values agree well with the titration presented in Fig. 3.

These *in vitro* findings strongly indicate that early endocytic vesicle fusion is arrested during mitosis and that this arrest is mediated by the cell-cycle control protein kinase cdc2. Although not directly shown here, this inhibition is expected to be the result of the protein-kinase activity of cdc2. Whether other fusion events are similarly inhibited in mitotic cells, accounting for the observed arrest of intracellular transport, remains to be determined. It is tempting to postulate that cdc2 kinase is part of the central regulatory mechanism controlling membrane traffic in mitotic cells. □

activation of *Prl* may require synergistic interactions with the enhancer region. Similar results were observed in transgenic mice[6].

To determine the structural features of GHF-1 responsible for its activity as a transcription factor, a series of internal deletion mutants was generated (Fig. 2). The ability of these mutants to activate the GH gene promoter was examined by a co-transfection assay in both F9 and Rat-6 cells. Although the extent of GH gene promoter activation in this assay was not as high as that observed in HeLa *MT-GHF1*$^+$ cells, because of a higher basal level, it was more convenient for screening a large number of mutant proteins. In this assay, activation of the GH gene promoter was also dependent on the presence of GHF-1-binding sites (data not shown).

Three different regions are required for efficient activation of *GH-CAT* by GHF-1. Deletion of amino-acid residues 2-45 and 48-73, within a serine-threonine-rich region, led to a large decrease in activity. Similarly, deletion of residues 124-201 encompassing the POU-specific domain, and residues 209-252 and 255-291 within the homoeodomain, had a strong deleterious effect. By contrast, deletion of residues 72-125 containing a cluster of negatively charged residues, and residues 200-211 constituting a putative hinge region between the POU-specific domain and the homoeodomain, did not impair activity. In fact, GHF-1 with a deletion of residues 72-125 (mutant Δ72-125) was more active than wild-type GHF-1. All of the mutants, with the exception of Δ125-201, which could not be tested because of the loss of the antigenic epitope, and Δ211-254, were efficiently expressed and accumulated in the nucleus (Fig. 2). Mutant Δ211-254 lacking the N-terminal half of the homoeodomain exhibited diffuse cytoplasmic fluorescence (data not shown) indicating that the nuclear translocation signal of GHF-1 is located within the deleted region.

The homoeodomain is the minimal DNA-binding domain of several proteins[14-16]. To analyse the DNA-binding domain of GHF-1, two chimaeric proteins were constructed, Jun-G123 and Jun-G202, by fusing the activation domain of c-Jun[17] to C-terminal GHF-1 sequences either containing the POU-specific domain (residues 123-291) or lacking the POU-specific domain (residues 202-291). Both chimaeras specifically activated *GH-CAT* expression; the one containing the POU-specific domain was fivefold more active than the one that lacked this region (Fig. 3*a*). The role of the POU-specific domain in DNA binding was also investigated by preparing two TrpE-GHF-1 fusion proteins. One, TrpE-GHF-1, contained the entire GHF-1 sequence (residues 1-291), whereas the other, TrpE-GHF(HB), contained the entire homoeodomain and only the C-terminal half of the POU-specific domain (residues 164-291; Fig. 3*b*). Footprinting (Fig. 3*c*) and mobility-shift (data not shown) experiments indicated that the protein containing the entire POU-specific domain exhibits 2.5- to 3-fold higher relative affinity than the protein lacking half of this motif. Most importantly, binding of the two proteins resulted in very similar DNase I protection patterns. As shown previously[8], these footprints were essentially identical to those generated by native GHF-1 purified from pituitary cells.

Although TrpE-GHF(HB) also lacks the N-terminal half of the protein, taken collectively, these results strongly indicate that the POU-specific domain of GHF-1 is not directly involved in making contact with the DNA, but somehow potentiates binding by the homoeodomain, which, as in other members of this family[14-16], is the minimal DNA-binding domain. It is possible that the POU-specific domain is responsible for increasing the binding specificity of GHF-1, because high concentrations of TrpE-GHF(HB) protect additional sequences not recognized by native GHF-1 (ref. 8). One possible explanation for the difference between our results and those of Sturm and Herr[18] is that, unlike GHF-1, Oct-1 could be more dependent on the POU-specific domain because of the lower intrinsic DNA-binding affinity of its homoeodomain.

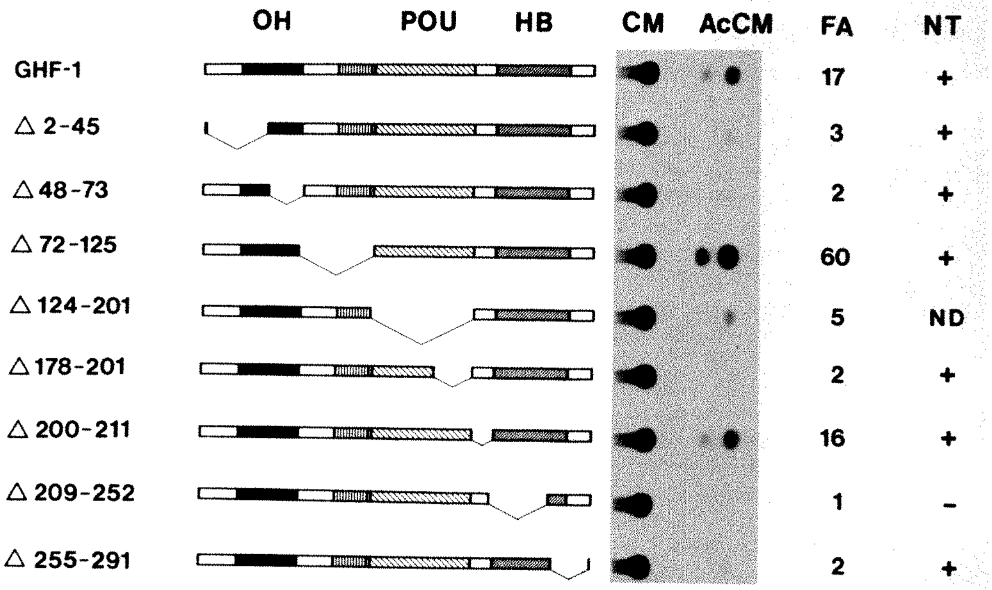

FIG. 2 Mutational analysis of GHF-1. The structure of GHF-1 and the internal deletion mutants are shown in a schematic form. Hatched boxes, homoeodomains (HB) and POU-specific domains (POU); striped boxes, regions rich in negatively charged residues; solid black boxes, regions rich in hydroxylated amino acids (OH); and open boxes, remainder of protein. Thin lines denote deleted sequences. Mutants are named according to the sequences affected by the deletions. The activities of the various constructs were tested by co-transfection with the *GH-CAT* reporter gene and determination of CAT activity. Results of one typical assay using Rat-6 cells are shown next to the diagram outlining the various constructs. Abbreviations: CM, chloramphenicol; acCm, acetylated chloroamphenicol. Fold activation (FA) is the activity of the various constructs relative to that of Δ209-252 which does not activate the GH gene promoter. Similar results were seen in two other assays in both Rat-6 and F9 cells. No activation of the construct containing the mutant GH gene promoter, *GH*Δ*(−82/−128)-CAT* (Fig. 1) was observed (data not shown). Nuclear transfer (NT) of the various proteins was determined by indirect immunofluorescence using an antibody specific for GHF-1. ND, not detected. These assays also served as controls for the quality of the transfections. Levels of GHF-1 expression were similar for all of the constructs indicated as NT positive (+).

METHODS. The *RSV-GHF-1* expression vector described in Fig. 1 was used as a template for generating by PCR[33] the various deletion mutants. Mutagenic primers were complementary to the sequences flanking the deleted regions such that one series of reactions generated 5′ fragments and the other 3′ fragments. These fragments were joined together to yield the final constructs, whose identity was confirmed by sequencing[34]. *GH-CAT* (5 μg) were transfected into Rat-6 or F9 cells on 10-cm plates together with 10 μg of the various expression vectors and 5 μg of carrier DNA, and CAT activity was determined 40 h later. Similar results were obtained in both F9 and Rat-6 cells. For immunofluorescence analysis, F9 cells were grown on cover slides and transfected as described above. Cells were fixed 10 h after removal of DNA precipitate and examined by indirect immunofluorescence with anti-GHF-1 antibodies[8].

Because the N-terminal half of GHF-1 is not involved in DNA binding, deletions of residues 2-45 and 48-73 probably affect the transcriptional activation domain. It is of interest that residues 1-73 contain only three sparsely spaced negatively charged residues, whereas residues 72-125, the deletion of which did not impair function, contain most (10 out of 13) of the negatively charged residues within the N-terminal domain. Therefore, residues 1-73 could constitute a novel activation domain that is different from the well-characterized negatively charged activation domains found in a variety of yeast and mammalian proteins[17,19-21]. Fusion of different portions of GHF-1 to the c-Jun DNA-binding domain, which recognizes the AP-1 binding site[17,22], confirmed these assertions. Despite possible interactions with endogenous Jun and Fos proteins, the c-Jun DNA-binding domain of the mutant protein JunΔ6-223 is practically inactive[17]. Fusion of GHF-1 residues 1-71 was sufficient to confer transcriptional stimulatory activity on the c-Jun DNA-binding domain (Fig. 4*a*). These experiments also indicate that residues 71-208 contribute very little to this activity. The primary sequence of the GHF-1 activation domain is shown in Fig. 4*b*.

The results described above demonstrate that the pituitary-specific transcription factor, GHF-1, is composed of two functional domains. The C-terminal half of this protein of relative molecular mass 33,000 (M_r 33K) contains its DNA-binding domain, whereas the N-terminal half is involved in *trans*-activation. Like other homoeodomain proteins[14-16], the minimal DNA-binding domain of GHF-1 is composed of its homoeodomain. The N-terminal portion of the homoeodomain is also likely to contain the nuclear transfer signal, a good candidate for which is a stretch of six contiguous basic residues between positions 213 and 219, similar to other nuclear transfer signals[23]. In addition to the homoeodomain, optimal DNA-binding requires the POU-specific domain. But, the exact part played by this motif is not clear because it does not seem to be involved in making contact with the specific binding sites for GHF-1. It is possible that the POU-specific domain stabilizes the protein–DNA complex and increases binding specificity by a so far unknown mechanism.

The N-terminal half of GHF-1 is responsible for *trans* activation. Construction of GHF-1–Jun chimaeric proteins enabled the demonstration that the first 71 amino-acid residues of GHF-1 function as an independent activation domain. This part of the protein contains only three sparsely spaced negatively charged residues and two glutamines (Fig. 4*b*). Therefore it bears no primary sequence homology to the two prototypes of activation domains described previously[19-21,24]. By contrast, more than 30% of the amino and residues in this region of GHF-1 are hydroxylated residues: serine, threonine and tyrosine. Because of phosphorylation, this region could constitute an acidic activator[21]. But immunoprecipitation of ^{35}S- and ^{32}P-labelled GHF-1 indicates that the extent of GHF-1 phosphorylation is very low (L. H. K. Defize, unpublished results). In addition, competition experiments indicate that the GHF-1 fails to compete against the acidic activation domain of c-Jun, whereas homologous competition is very efficient (unpublished results). We conclude therefore that the activation domain of GHF-1 represents a new class of activation domains.

So far the essential structural features of this domain are not known. The most remarkable feature of this part of GHF-1, however, is the abundance of hydroxylated amino acids. (Fig. 4*b*) and therefore, we have named it the STA domain (Ser-Thr-rich activation domain). It is noteworthy that two other members of the POU-domain family, Oct-2 and Unc-86, both of which are cell type-specific activators, contain regions that are abundant (>30%) in hydroxylated amino acids. In Oct-2 this region is located near its C terminus[25-27], and in Unc-86 it is located immediately upstream of the POU-domain[28]. Two other cell type-specific *trans*-acting factors that do not belong to the homoeodomain family, MyoDl and Myf-5, also contain Ser-Thr-rich regions[29]. At least for Oct-2, this region could be important for *trans*-activation (W. Herr, personal communication). Although Ser-Thr-rich regions are also present in Spl they are dispensible for transcriptional activation in *Drosophila* cells[24];

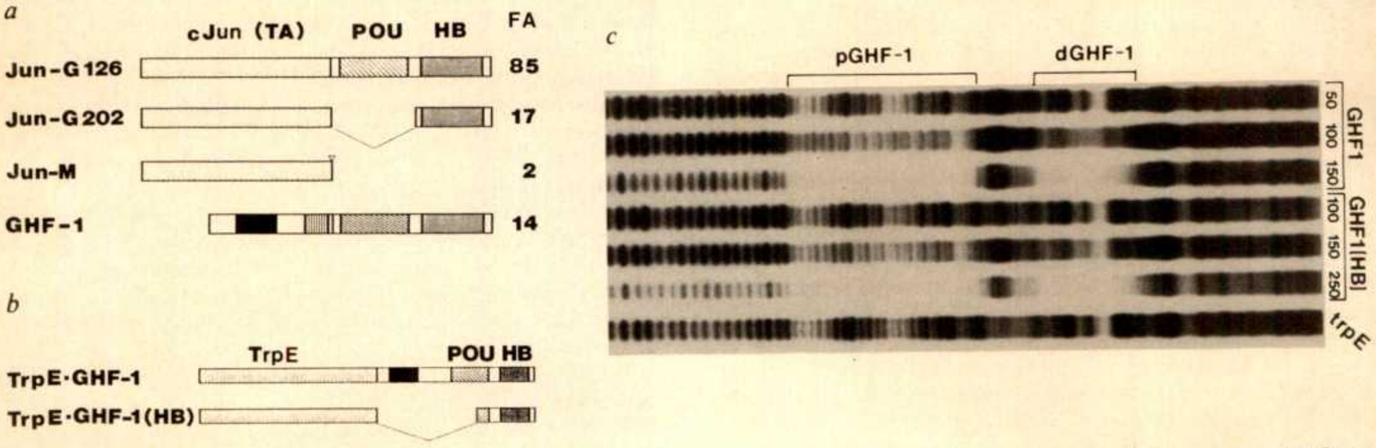

FIG. 3 Role of the POU-specific domain. *a*, Structure and activities of chimaeric Jun–GHF-1 constructs. Dotted box, c-Jun activation region (amino-acid residues 1–193); other symbols denote GHF-1 sequences as described in (Fig. 2). The activities of these constructs were determined by transfection of F9 cells with 10 μg of expression vector and 5 μg *GH-CAT* or *GHΔ(−82/−128)-CAT* lacking GHF-1-binding sites. Basal *GH-CAT* expression was determined by co-transfection with RSVcJunΔ6-223, which lacks the activation region[17] and was given an arbitrary value of 1. Fold activation (FA) was determined relative to this value and represents the average of two different experiments. Expression of *GHΔ(−82/−128)-CAT* was not affected by any of the expression vectors (data not shown). *b*, Structure of the TrpE-GHF-1 and TrpE-GHF(HB) fusion proteins. Dotted box, TrpE N-terminal region (M_r 37K); other boxes denote GHF-1 sequences as described above. *c*, Footprint analysis of the DNA-binding specificities of TrpE-GHF-1 and TrpE-GHF(HB). End-labelled human GH gene promoter fragment (+3 to −500; labelled at +3) was incubated with increasing amounts (ng) of the two fusion proteins as indicated, or 400 ng plasmid p 37^{trpE} and subjected to DNase I footprinting.

METHODS. To construct Jun-G126 and Jun-G202, *Bgl*II–*Asp*718 DNA fragments from *Δ72–125* and *Δ124–201* (containing the sequences encoding the GHF-1 POU–HB and HB, respectively) were inserted into *c-JunΔ194–223* (ref. 17) replacing the c-Jun DNA-binding domain. c-Jun-M contains the c-Jun activation domain (amino-acid residues 1–193) and lacks the DNA-binding domain[17]. Transfections were as described above. TrpE-GHF-1 was constructed by inserting a 0.9-kb *Bam*HI-*Hin*dIII fragment containing the complete GHF-1 gene coding region into the polylinker region of plasmid pATH3 which contains the TrpE N-terminal-encoding region, coding for p37^{trpE} (ref. 22). *trpE-GHF*(*HB*) contains an *Eco*RI fragment corresponding to GHF-1 amino-acid residues 164–291 as previously described[8]. Preparation of TrpE fusion proteins, gel-retardation assays (not shown), and DNase I footprinting reactions as previously described[8]. Amounts of proteins were determined by silver staining.

FIG. 4 GHF-1 contains a novel activation domain. *a*, Structures and activities of chimaeric constructs, containing N-terminal fragments of GHF-1 fused to the DNA-binding domain of c-Jun (dotted box). The activities of these constructs were determined by transfections of F9 cells with 10 μg expression vector and 3 μg of *−73-Col-CAT*, which contains an AP-1-binding site[17,22] and assaying CAT activity 20 h later. Fold activation (FA) is relative to the basal expression of *−73-Col-CAT*, which was determined by co-transfection with *JunΔ6-223* (ref. 17) and represents the average of three separate experiments. *b*, Primary structure of the GHF-1 activation domain. The serine, threonine and tyrosine residues are highlighted (single-letter amino-acid code).
METHODS. To construct *G208-Jun*, *G123-Jun* and *G71-Jun*, a 1.6-kb *Bgl*II-*Asp*718 DNA fragment corresponding to the c-Jun DNA-binding domain was isolated from RSVcJunΔ194-223 (ref. 17) and inserted in-frame into *Δ209-252*, *Δ124-201* and *Δ72-125*, respectively.

but it is possible that in other cell types these regions are active. It is of interest that the STA domain has a similar composition to the C-terminal repeat of the largest subunit of RNA polymerase II (ref. 30). In addition to hydroxylated residues, these regions contain several prolines, indicating that they do not form α-helices. It is possible that the STA domain may contact directly, by hydrogen bonding, the C-terminal domain of the largest subunit of RNA polymerase II. Because the C-terminal domain of the largest subunit is subject to phosphorylation[31], it is more likely to make contact with the hydroxylated or basic amino-acid residues than acidic residues as previously suggested[32]. □

ACKNOWLEDGEMENTS. We thank J. Meek for help with immunofluorescence and artwork, L. H. K. Defize for immunoprecipitations, K. Hattori for oligonucleotide synthesis, L. Haberstroh for help with luciferase assays, P. Angel for the Jun constructs, A. Gutierrez-Hartmann for RSV-Luc3A, K. Jones and B. Emerson for critical reading of the manuscript, and D. Caruso and P. Bucher for the preparation of the manuscript. L. E. T. and J. L. C. were supported by the Danish Medical Research Council and EMBO postdoctoral fellowships, respectively. Work was supported by the NIH.

A highly divergent HIV-2-related isolate

Ursula Dietrich, Michalina Adamski, Renate Kreutz, Anja Seipp, Herbert Kühnel & Helga Rübsamen-Waigmann

Chemotherapeutisches Forschungsinstitut, Georg-Speyer-Haus,
Paul-Ehrlich-Strasse 42-44, 6000 Frankfurt 70, FRG

IT has been suggested that the human immunodeficiency virus type 2 (HIV-2) and the simian immunodeficiency virus from rhesus macaques (SIV$_{\mathrm{mac}}$) evolved from the sooty mangabey virus SIV$_{\mathrm{sm}}$ (ref. 1). We now describe an HIV-2-related isolate, HIV-2$_{\mathrm{D205}}$, from a healthy Ghanaian woman that is genetically equidistant to the prototypic HIV-2 strains and to SIV$_{\mathrm{sm}}$ and SIV$_{\mathrm{mac}}$. Supported by the observation that HIV-2$_{\mathrm{D205}}$ differs in a step of envelope glycoprotein processing, our data indicate that it could represent an alternative HIV-2 subtype and that viruses of the HIV-2/SIV$_{\mathrm{sm}}$/SIV$_{\mathrm{mac}}$ group could have already infected humans before HIV-2 and SIV$_{\mathrm{sm}}$/SIV$_{\mathrm{mac}}$ diverged.

We have previously reported the molecular cloning of HIV-2$_{\mathrm{D205}}$ (ref. 2). This isolate from a healthy woman from Ghana was biologically characterized by its good growth on macrophages and by the absence of cytopathic effects on lymphocytes. It was originally classified as HIV-2 by western blot analysis.

We have now determined the complete nucleotide sequence of the clone HIV-2$_{\mathrm{D205,7}}$, which encompasses 7,817 base pairs (bp) of the proviral genome starting from the left long terminal repeat (LTR). We compared the sequence with the known HIV and SIV sequences (Table 1). Surprisingly, HIV-2$_{\mathrm{D205,7}}$ is only 76.2–76.8% identical to the other HIV-2 strains sequenced so far (strains ROD[3], D194[2], NIHZ[4] and ISY[5]). But the relationship of HIV-2$_{\mathrm{D205,7}}$ to SIV$_{\mathrm{sm}}$ (ref. 1; 76.4% nucleotide-sequence identity), SIV$_{\mathrm{mac}}$ (ref. 6; 75.0%), SIV$_{\mathrm{agm}}$ (ref. 7; 58.2%) and HIV-1$_{\mathrm{BRU}}$ (ref. 8; 57.8%) is in the same range as for the other HIV-2 isolates. HIV-2$_{\mathrm{D205}}$ is, therefore, genetically equidistant to the other HIV-2 strains and to SIV$_{\mathrm{sm}}$ and SIV$_{\mathrm{mac}}$. For comparison, the identity between the other HIV-2 strains is 87–90%, their identity to SIV$_{\mathrm{sm}}$ is 76.5–77.7%, and that to SIV$_{\mathrm{mac}}$ is 75.3–76.3%.

The genetic organization of HIV-2$_{\mathrm{D205}}$ is the same as for HIV-2, SIV$_{\mathrm{sm}}$ and SIV$_{\mathrm{mac}}$. Many of the open reading frames (*orf*) of HIV-2$_{\mathrm{D205}}$ differ in length only by one or a few codons from the *orf* of HIV-2$_{\mathrm{ROD}}$. The most notable difference is a

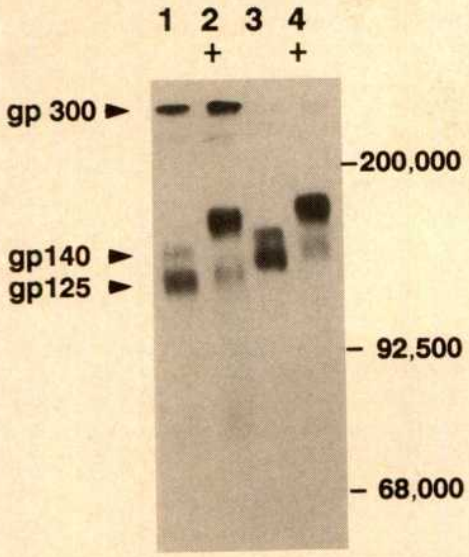

FIG. 1 Size comparison of the external glycoproteins (gp) of HIV-2_{ROD} and HIV-2_{D205}. [^{35}S]cysteine-labelled proteins from cells infected with HIV-2_{ROD} (lanes 1, 2) and HIV-2_{D205} (lanes 3, 4), immunoprecipitated by HIV-2-positive serum, and separated on an 8.5% SDS polyacrylamide gel. The external gp of HIV-2_{ROD} (gp125), its precursor (gp140), the dimeric form of gp140 (gp300), and the positions of M_r markers are indicated. In HIV-2_{D205}-infected cells, the band corresponding to the dimer is missing, even after treatment with castanospermine (lane 4), an inhibitor of glucosidase I, which causes the dimeric form to accumulate in HIV-2_{ROD} (lane 2). Notice that the external gp and its precursor are larger in HIV-2_{D205} than in HIV-2_{ROD}.

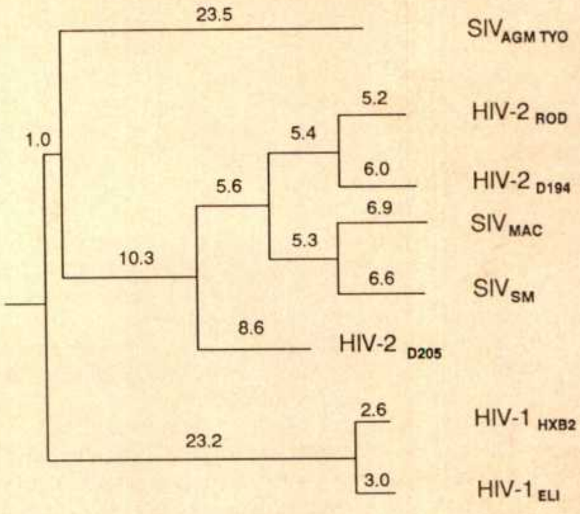

FIG. 2 Minimum-length evolutionary tree showing the relationship of HIV-2_{D205} to the HIV and SIV lentiviruses. The tree was generated from single base substitutions in the 3′ part of the HIV-$2_{D205.7}$ sequence using the PAUP program[13] and version 3.21 of the PHYLIP[14] bootstrapping algorithm. The tree was rooted on a random sequence. The total number of sites examined was 2,664; total number of variable sites, 1,548; consistency index, 0.746. Horizontal distances are proportional to the minimum number of single nucleotide substitutions required to generate the sequence examined or to the actual branch lengths indicated as fractional steps, that is, percentage of total sites.

54-bp insertion in the *gag-pol* overlap, followed by a 54-bp deletion, which puts the codons in phase again. This deletion, but not the insertion, is also present in the *gag-pol orf*s of SIV_{sm} and SIV_{mac}. In addition, the *gag-pol* overlap of HIV-2_{D205} is 60 nucleotides longer than it is in HIV-2_{ROD}, resulting in a *pol orf* that is extended by 20 codons at the 5′ end. We found some minor *orf*s by examining the DNA (+) strand. One of them, at position 1,851–1,651 on the lower strand of the HIV-$2_{D205.7}$ sequence, is conserved between all HIV-2 isolates, as well as in SIV_{mac} and SIV_{sm} (data not shown), and was preliminarily named *orf-y*. We predicted the deduced amino-acid sequence to constitute a small very hydrophobic protein of relative molecular mass 7,300 (M_r 7.3). Although there is, so far, no evidence for the transcription of the DNA (+) strand, of retroviruses, its remarkable conservation implies that it could have a function.

We compared the sequences of single genetic units from HIV-2_{D205}, HIV-2_{ROD}, SIV_{sm} and SIV_{mac}, and found that variability ranges from 4.6% (for genetic unit *R*) up to 35.9% (for *rev* exon 1) on the nucleotide level, and from 12.8% (for *gag*) up to 47.6% (for *rev* exon 1) at the amino-acid level (Table 2). But functionally relevant sequences or protein characteristics (such as hydrophilicity or charge) are highly conserved. For example, the identity of the complete LTR of HIV-2_{D205} to that of HIV-2_{ROD} is 84.5%, whereas the identity for TAR, the region necessary for the *trans*-activation by Tat[9,10], or the binding site for the transcription factor NF-κB (ref. 11), is 100%. The primer-binding site is 100% complementary to the 3′ end of the transfer RNA for lysine and the 'shifty sequence' TTTTTT, which catalyses the ribosomal frameshift between the *gag* and *pol orf*s, is unaltered. The sequenced part of the external glycoprotein of HIV-2_{D205} is 33% divergent from that of HIV-2_{ROD}, but has the same pattern of conserved and variable domains as the other HIV-2 and SIV_{sm}/SIV_{mac} strains[10]. All cysteine residues in the external glycoprotein of HIV-2_{ROD} are conserved. Divergence in the external glycoproteins is due to single amino-acid exchanges and small deletions or insertions, mainly in the variable regions. In addition, 8 out of 21 potential N-glycosylation signals differ between HIV-2_{D205} and HIV-2_{ROD}, indicating the importance of glycosylation in the generation of envelope variability.

To further characterize HIV-2_{D205}, we immunoprecipitated viral proteins and analysed them by SDS-PAGE. It is noteworthy that the envelope precursor glycoprotein, which forms a dimer in HIV-2 and SIV_{mac} to be processed correctly[12], was not dimeric in HIV-2_{D205} (Fig. 1). Furthermore, the external glycoproteins of HIV-2_{D205} and its precursor have higher apparent M_rs than those of HIV-2_{ROD}. This difference was also observed when glycosylation was inhibited (M.A., manuscript in preparation).

To determine the position of HIV-2_{D205} in the phylogenetic tree of lentiviruses, we constructed minimum-length evolutionary trees[13]. The tree based on the nucleotide variation in the 3′ part of the HIV-$2_{D205.7}$ sequence is shown in Fig. 2. HIV-2_{D205} is located remarkably close (8.6% difference) to a hypothetical

TABLE 1 Nucleotide sequence identity between HIV and SIV viruses (in %)

Strain	HIV-2 ROD	 D194	 NIHZ	 ISY	SIV sm	 mac	 AGM	HIV-1 BRU
HIV-$2_{D205.7}$	76.8	76.2	76.4	76.7	76.4	75.0	58.2	57.8
HIV-2_{ROD}	—	87.0	90.1	89.3	77.7	76.3	58.0	57.0
SIV_{mac251}	76.3	75.3	76.4	75.8	84.6	—	58.7	55.0

Sequences were obtained from the Los Alamos HIV Sequence Database[10] and compared using Microgenie sequence software from Beckman.

common ancestor of the HIV-2/SIV_{sm}/SIV_{mac} group of lentiviruses and branches before SIV_{sm}/SIV_{mac} diverged from the HIV-2 prototypes. In the tree, HIV-2_{D205} is 25% different from the prototypic HIV-2 viruses and 26% different from SIV_{sm} and SIV_{mac}, which agrees with our nucleotide-sequence comparison data in Table 1. This tree was congruent with the majority tree for the 5′ half of the genome. Bootstrapping, using version 3.21 of the PHYLIP algorithm[14], led to the same branching order in 40 out of 50 replicates. Branching length and branching order in this tree were in good agreement with those of other work (for example, see Fig. 4 of ref. 1). In the evolutionary tree analyses, the rarest occurrence was the clustering of HIV-2_{D205} with the prototypic HIV-2 viruses; sometimes HIV-2_{D205} clustered with SIV_{sm}/SIV_{mac}, but it usually appeared by itself as a close relative of the progenitor of both.

Our data indicate that the HIV-2/SIV_{sm}/SIV_{mac} group of viruses is older and genetically more divergent than previously believed. This antiquity, along with a high degree of variability, presumably accounts for the development of different subtypes: the HIV-2 prototypes, an alternative subtype defined by the strain HIV-2_{D205}, described here, and the simian strains SIV_{sm} and SIV_{mac}. The alternative subtype defined by HIV-2_{D205} is characterized by the high sequence divergence (24%) from that of the HIV-2 prototypes, and by the absence of dimer formation of the envelope protein precursor (Fig. 1), which is believed to be a necessary step in the processing of the envelope glycoproteins in the prototypic HIV-2 viruses and in SIV_{mac}. In this respect, HIV-2_{D205} behaves like HIV-1, in which no dimer formation has been observed.

To emphasize both the alternative subtype of HIV-2_{D205} and its evolutionary location close to a hypothetical common ancestor of the HIV-2/SIV_{sm}/SIV_{mac} group of lentiviruses, we propose that the virus is called HIV-2_{ALT}.

In our evolutionary tree, HIV-2_{ALT} is closely related to this common ancestor and branches earlier than SIV_{sm}/SIV_{mac} and the HIV-2 prototypes. Thus, the question of the origin of HIV-2 is open again. It is still unclear whether the host of a common ancestor of the HIV-2/SIV_{sm}/SIV_{mac} group was human or simian. A horizontal infection of a human by sooty mangabey seemed plausible because of the extent of sequence identity and the endemic coincidence[1,15]. But it must be noted that SIV_{sm} and SIV_{mac} are viruses taken from captive animals and that sequence data of SIV_{sm} from wild animals have not yet been published. Because captive monkeys were injected with human material back in the 1960's, artificial transmission from a human to a simian host could have occurred. It is possible, therefore, that SIV_{sm} and SIV_{mac} are fundamentally human viruses. In addition, the finding of HIV-2_{ALT}, a virus in a human, which is evolutionarily older than SIV_{sm}, could indicate that all subtypes of the HIV-2/SIV_{sm}/SIV_{mac} group are of human origin.

TABLE 2 Sequence conservation of genetic units (nucleotide/amino-acid)

HIV-2_{D205} genetic unit	% Identity to: HIV-2_{ROD}	SIV_{sm}	SIV_{mac251}

nef (partial)	73.5/72.1	66.5/62.8	66.6/58.3

Identity between HIV-$2_{D205,7}$ and HIV-2_{ROD}, SIV_{sm} and SIV_{mac} allocated to single genes and LTR regions; *nef* from SIV_{sm} extends further downstream and was only compared up to the position corresponding to the stop codon of HIV-2 and SIV_{mac}.

On the basis of epidemiological data it has been proposed[16] that HIV-2, or at least a subtype of HIV-2, is less pathogenic in humans than is HIV-1. HIV-2_{ALT}, originating from a healthy Ghanaian, could be of this kind, as its position in the tree indicates that there exist viruses that had time to adapt to their human hosts. In addition, some individuals could have already evolved protective mechanisms that prevent certain HIVs from causing lethal disease. But out of the fifty cases of HIV-2 infection diagnosed in Germany so far, three have been fatal, one of them showing exclusively neurological symptoms[17]. Clearly, among viruses that serologically react like HIV-2, there are strains with very different genetic and biochemical properties. Thus, for further investigations on the spread of HIV-2 and its pathogenicity, it may be important to distinguish between the prototypic HIV-2 strains and the HIV-2_{ALT} subtypes. ☐

THE two main proteins involved in muscular contraction and cell motility, myosin and actin, possess the intrinsic property of being able to form filamentous structures[1]. This property poses a serious impediment to the study of their structures and interactions, and a considerable effort has thus been made to isolate their functional domains. The globular part of myosin, subfragment-1 (S1), which possesses ATPase and actin-binding sites as well as supporting the movement of actin filaments during *in vitro* assays, has been isolated[2–4]. But because S1 is efficient in inducing actin polymerization[5,6], as is myosin, it has not been possible to prepare and characterize a complex of S1 with monomeric actin (G-actin). We have now used chromatographically purified proteins to show that only the S1 isoenzyme carrying the A1 light-chain subunit promotes actin polymerization. The other isoenzyme, S1 (A2), carrying the A2 light-chain subunit, binds to actin, forming a tight complex of G-actin and S1 in a 1:1 ratio. This new functional difference

between myosin isoforms directly implicates the A1 light-chain in myosin-induced actin polymerization. Additionally, this finding should lead to the purification of the stable G-actin–S1 complex needed to resolve the structure and to understand the molecular dynamics of the actin–myosin system.

Two principal myosin isoforms have been defined on the basis of the heterogeneity of the 'alkali' light-chain subunits, A1 and A2, bound to the globular heads of myosin[7]. Thus the two isoforms of the skeletal myosin head, S1(A1) and S1(A2), differ in the composition of their light chains: the A1 subunit of S1(A1) has an additional 41 N-terminal amino acids[8]. At low ionic strength, this difference alters both the actin-activated Mg^{2+}-dependent ATPase of S1, and the affinity of S1 for filamentous actin (F-actin)[9-11]. In more physiological conditions, and in the presence of the muscle regulatory system, this difference results mainly in a higher binding of S1(A1) isoenzyme to F-actin[12].

We first investigated whether both isoenzymes of S1 polymerize actin in the same fashion by measuring the amount of protein polymerized by each isoenzyme after a high-speed centrifugation (Fig. 1*A*). The addition of S1(A1) to a solution of G-actin induced the formation of filamentous actin co-sedimenting with an equimolar amount of S1(A1). When we used S1(A2), however, both actin and S1(A2) remained in the supernatant, indicating that actin polymerization had not occurred. By contrast, control experiments showed that both S1(A1) and S1(A2) normally bind to F-actin and cosediment with it (Fig. 1*A*, lanes d, Sd, e, Se). We established unequivocally the lack of actin polymerization in the presence of S1(A2) by performing light-scattering experiments (Fig. 1*B*). The addition of S1(A2) to G-actin did not modify the intensity of scattered light, confirming the absence of actin polymer in the solution. By contrast, S1(A1) gradually increased the intensity of light-scattering of the actin solution, demonstrating that actin polymerization had occurred. Further analysis of the last result showed that, in contrast to a previous report[13], the time course of the S1(A1)-induced polymerization resembles that of salt-induced polymerization[14]—that is, a lag phase, usually interpreted as the activation and nucleation phase of the actin monomer, precedes the elongation phase of the actin polymer.

Although S1(A2) does not polymerize actin, it does form a tight complex with monomeric actin. By measuring fluorescence polarization of chromophoric labels attached to actin, we could detect changes in the hydrodynamic volume of the protein, normally occurring during the formation of G-actin–S1 complexes or during actin polymerization[15]. When S1(A2) was added to G-actin labelled with 1,5-IAEDANS(5-[2-(iodoacetyl)-aminoethyl]aminonaphthalene-1-sulphonic acid), the polarization rapidly increased from its initial value of 0.23 to 0.33 (Fig. 2*a*). These values agree reasonably well with theoretical calculations, which give polarization values of 0.22 and 0.345 for the

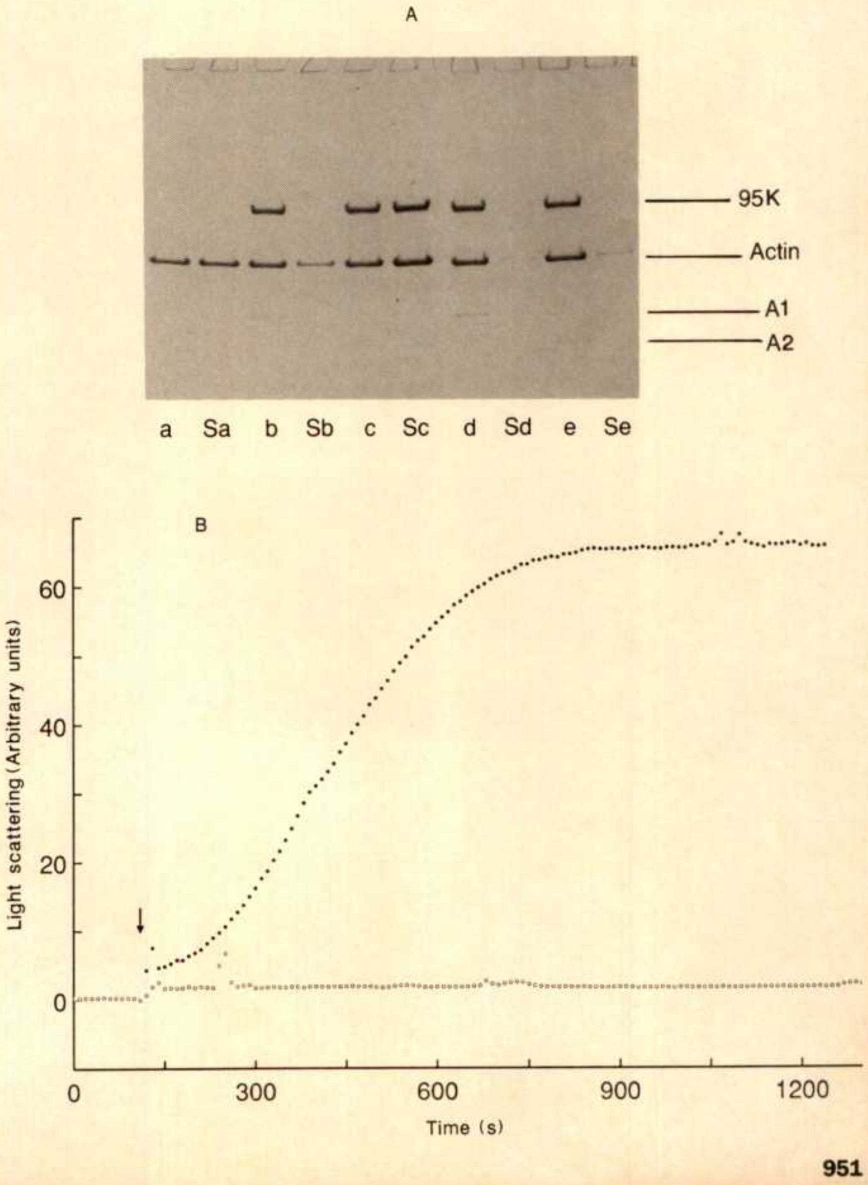

FIG. 1 A, G-actin polymerization followed by co-sedimentation experiments. a, G-actin alone (18 μM); b, d, G-actin mixed with S1(A1) (15 μM); or c, e, S1(A2) (15 μM); were centrifuged for 60 min at 160,000*g* after incubation for 30 min at 20 °C in G buffer (a, b, c) or in G buffer supplemented with 2 mM $MgCl_2$, 0.2 mM EGTA (d, e). Aliquots were withdrawn before (a–e) and after (Sa–Se) centrifugation and were loaded on 3.5–18% gradient polyacrylamide gel. Position of S1 heavy chain shown as 95K (*M*, 95,000). B, G-actin polymerization detected by light scattering. Time course of light scattering at 90° ($\lambda_{\text{excitation}}$ = 600 nm) of G-actin (11 μM) in G buffer observed after the addition (arrow), of 13 μM S1(A1) (●) or S1(A2) (○).

METHODS. S1 isoenzymes S1(A1) and S1(A2) were prepared from rabbit skeletal muscle myosin as previously reported[19] and were kept on ice in Tris-HCl buffer (30 mM), NaN_3 (0.1 mM), dithioerythritol (0.2 mM), pH 7.8. G-actin was extracted from the acetone powder of muscle of the same type as S1 (ref. 20), and further purified by G-150 gel chromatography using a column equilibrated with G buffer (Tris-HCl buffer, 2 mM; $CaCl_2$, 0.2 mM; ATP, 0.1 mM; DTE, 0.2 mM; NaN_3, 0.1 mM, pH 7.8). Protein concentrations were determined from absorbance[10,21].

monomeric actin and the G-actin–S1 complex, respectively[16]. For S1(A1), the polarization increased initially to 0.37, but rather than remaining stable, it further slowly increased to 0.44, the value characteristic for F-actin. We interpreted these observations as follows. When either of the S1 isoenzymes is mixed with G-actin, it forms a G-actin–S1 complex. Whereas the G-actin–S1(A2) complex does not change its aggregation state, the G-actin–S1(A1) complex has a strong tendency to form filamentous structures. This ability of the complex to polymerize must be due to the presence of the extra N-terminal residues of the A1 light chain, which were shown to directly interact with amino-acid residues 360, 362 and 364 of actin[17,18]. Whether actin polymerization results in the binding of the A1 light chain and the heavy chain to the same or to different actin monomers remains to be determined. Fluorescence polarization data, however, support the formation of a 1:1 G-actin–S1 complex in an early stage of the polymerization process. Furthermore, from fluorescence anisotropy titration of G-actin with S1(A2) (Fig. 2*b*), we determined that the number of S1(A2)-binding sites on G-actin per G-actin monomer is 1.1 and that the dissociation constant (K_d) for the complex formation is 0.4 μM.

Because of the sensitivity of the G-actin–S1(A2) complex to ATP, it is not possible to purify the complex in the ATP-containing buffer needed for G-actin stability. Therefore we developed a method of preparing a covalent G-actin–S1(A2) complex by crosslinking G-actin to S1(A2) at 4 °C using EDC (1-ethyl-3[3-(dimethylamino)-propyl]carbodiimide) as a catalyst. The purification of this complex by gel filtration chromatography yielded a product that was contaminated by traces of S1(A2) but entirely free of monomeric actin (Fig. 3). This complex was eluted from the column in about the same volume as was the relative molecular mass (M_r) standard (M_r 158,000), and therefore was certainly composed of G-actin and S1 in a 1:1 ratio (M_r 155,000), corroborating the results of the spectroscopic measurements.

Although a more complete investigation is needed to understand in detail the mechanism of the S1(A1)-induced actin polymerization, it is interesting to note that the A1 light chain is present only in myosin from skeletal or cardiac muscle. So, smooth muscle or nonmuscle myosins which possess A2-like light chains, may not polymerize actin. Whether this functional difference between the two S1 isoforms has physiological sig-

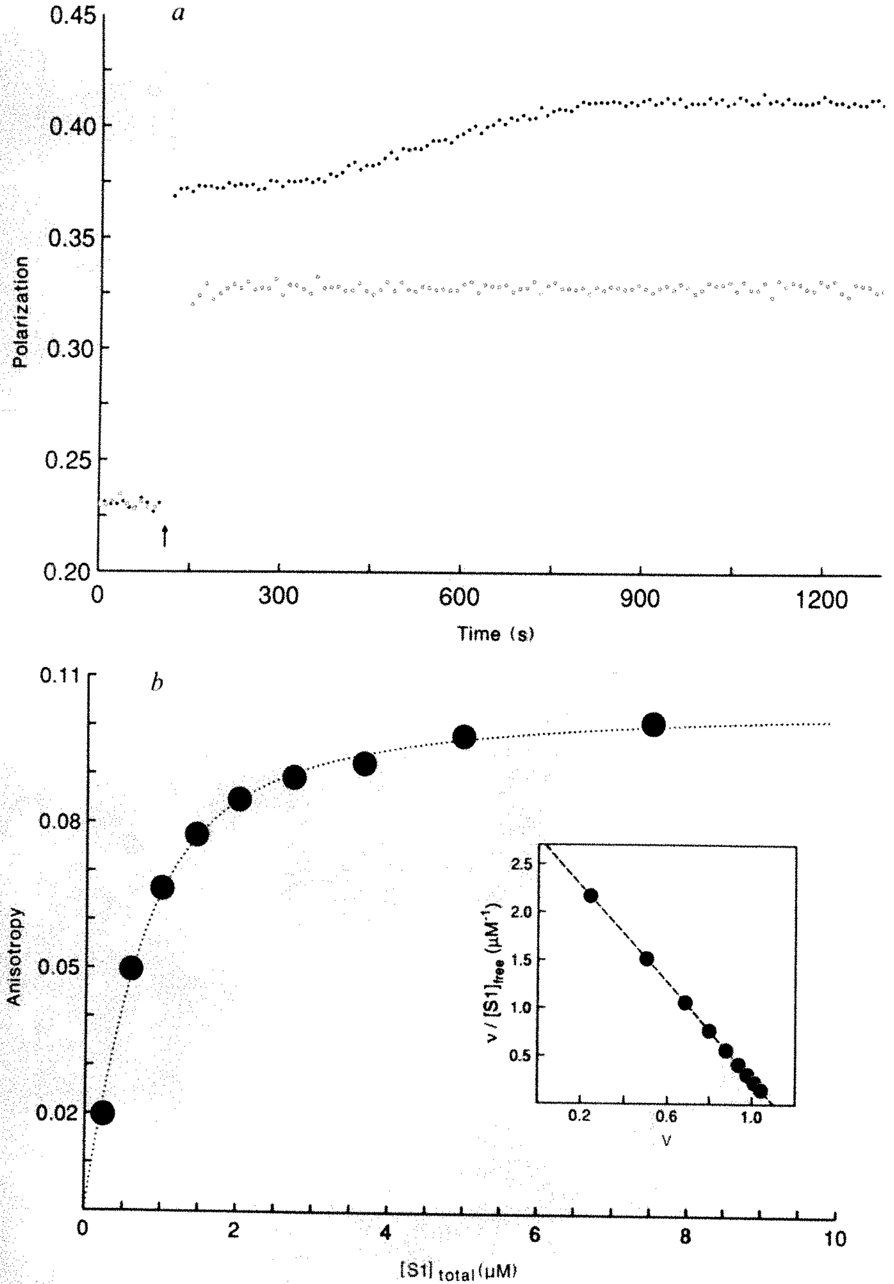

FIG. 2 *a*, Effect of S1(A1) and of S1(A2) on the fluorescence polarization of 1,5-IAEDANS-labelled actin. S1(A1) (13 μM; ●) or S1(A2) (13 μM; ○) were added (arrow) to a solution of 1,5-IAEDANS-labelled G-actin (11 μM) in G buffer. *b*, Titration curve of 0.5 μM 1,5-IAEDANS-labelled G-actin by S1(A2). The values of fluorescence anisotropy and the fraction of bound protein were calculated from polarization data as described[22]. Insert, Scatchard plot of the data where *v* is the fraction of S1 bound to actin.

METHODS. Actin was labelled with 1,5-IAEDANS according to ref. 23 and purified on a G-150 gel filtration column. Polarization measurements were performed at 20 °C on an SLM 8000 fluorometer.

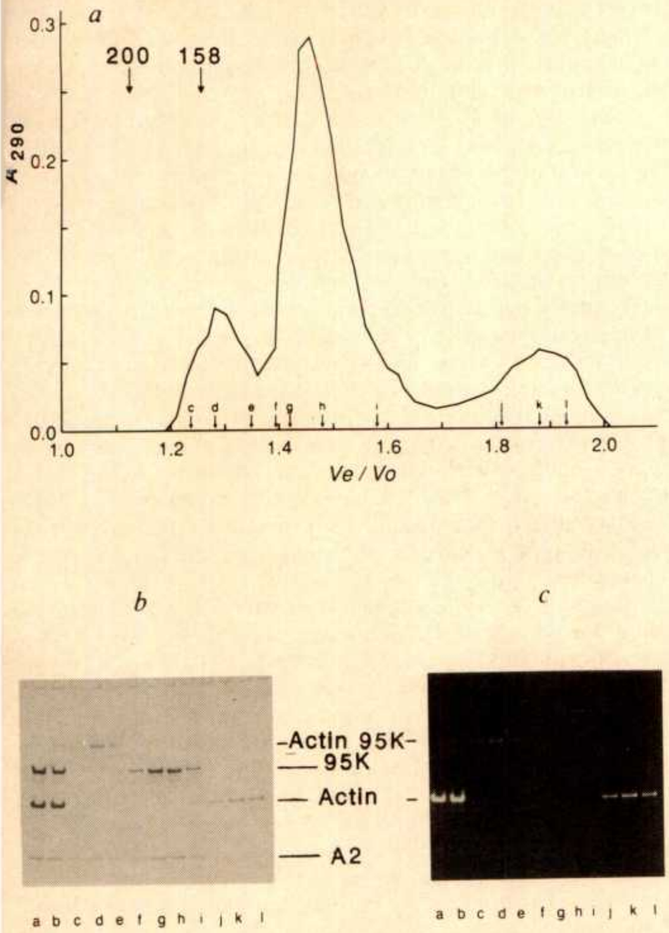

FIG. 3 Purification of the covalent G-actin–S1(A2) complex. *a*, Elution profile of EDC-crosslinked G-actin–S1(A2) complex from a Sephadex G-150 column. Abbreviations: V_e, elution volume; V_0, void volume. Aliquots of fractions c–l were loaded on SDS-PAGE and stained with Coomassie blue (*b*) or viewed in the ultraviolet light (*c*). Lanes a and b, composition of 1,5-IAEDANS-labelled G-actin–S1(A2) mixture before and after EDC-catalysed crosslinking reaction, respectively.

METHODS. 1,5-IAEDANS-labelled G-actin (40 μM) and S1(A2) (50 μM) were mixed in G buffer at 4 °C and a solution of EDC was added to a final concentration of 10 mM. During the 50 min of the crosslinking reaction, the mixture was centrifuged at 160,000*g*, 4 °C. The supernatant was then collected, the reaction was stopped with a 100-fold molar excess of DTE, and the sample was loaded on a G-150 column (2.5 × 140 cm) equilibrated with G buffer at 4 °C. M_r standards ($M_r \times 10^{-3}$): aldolase, 158; α-amylase, 200.

nificance is not clear, because in the presence of 0.5 mM $MgCl_2$, the G-actin-S1(A2) complexes spontaneously form filaments (data not shown). Nonetheless, both the noncovalent and covalent complexes described here are undoubtedly useful for further functional and structural studies, as they provide potential samples for the crystallization and the resolution of the three-dimensional structure of the native G-actin–myosin head complex. ☐

Sensitivity to cyclosporin A is mediated by cyclophilin in *Neurospora crassa* and *Saccharomyces cerevisiae*

CYCLOSPORIN A, a cyclic fungal undecapeptide produced by *Tolypocladium inflatum*, is a potent immunosuppressive drug originally isolated as an antifungal antibiotic[1,2]. Cyclosporin A (CsA) is widely used in humans to prevent rejection of transplanted organs such as kidney, heart, bone marrow and liver[3]. The biochemical basis of CsA action is not known: its primary cellular target has been suggested to be calmodulin[4,5], the prolactin receptor[6,7] or cyclophilin, a CsA-binding protein originally isolated from the cytosol of bovine thymocytes[8–10]. Cyclophilin has been shown to be a highly conserved protein present in all eukaryotic cells tested[11–15] and to be identical[16,17] to peptidyl–prolyl *cis-trans* isomerase[18,19], a novel type of enzyme[20] that accelerates the slow refolding phase of certain proteins *in vitro*[21,22]. We demonstrate that in the lower eukaryotes *N. crassa* and *S. cerevisiae*, cyclophilin mediates the cytotoxic CsA effect. In CsA-resistant mutants of both organisms, the cyclophilin protein is either lost completely or, if present, has lost its ability to bind CsA.

We selected for CsA-resistant mutants in the St Lawrence 74A wild-type strain of *N. crassa* by applying the lowest CsA concentration (1 μg ml^{-1}) found to prevent growth. Forty-one ultraviolet-induced mutant strains were isolated and four of those, belonging to a high-resistance class (B9; B12; B27; B32; all growing on 10 μg ml^{-1} CsA), were crossed to a double-mutant strain *pan-2 arg-12* to combine the CsA-resistance with 'forcing markers' for heterokaryon formation. We performed the same procedure with a spontaneous mutant (B60) which grew on 5 μg ml^{-1} CsA. In all five crosses, CsA-resistant and CsA-sensitive segregants occurred in a 1:1 ratio, indicating the involvement of a single gene in each case. Segregants that carried each mutation in wild-type background were selected for biochemical analysis (Fig. 1); segregants with mutations in combination with either *pan-2* or *arg-12* markers and mating type *A* were selected for dominance and complementation tests. We found all five CsA-resistant mutations to be recessive in mycelia that were heterokaryotic for either one of them and the CsA-sensitive wild-type allele. Mycelia heterokaryotic for pairs of CsA-resistant mutations displayed the CsA-resistant phenotype, that is, they were unable to complement each other. Apparently the five mutations are allelic, indicating that a single gene, which we name *csr-1*, is responsible for CsA-resistance. Because we noticed a weak linkage (~33%) between CsA-resistant mutations and mating type *a*/*A* alleles (located on *N. crassa* linkage group I), mutant B12 was crossed to markers on chromosome I, that is *nit-2* (left arm) and *his-2* (right arm). We observed linkage with *his-2* with 19.5% recombination. The linkage with the mating type locus, and *his-2* allows us to position *csr-1* distal from *his-2* on the right arm of chromosome I.

All mutants grew normally at 25 °C. We also tested them for growth at 29 °C and 37 °C, but no temperature-sensitivity was observed.

In wild-type strains of *N. crassa* cyclophilin is located in both cytosol and mitochondria[14]. Both forms are encoded by a single nuclear gene, which is transcribed into two messenger RNAs with different 5'-ends. The shorter mRNA codes for the cytosolic form of relative molecular mass 20,000 (M_r 20K), whereas the longer mRNA codes for a 24K precursor protein whose N-terminal presequence is cleaved, in two steps, on import into mitochondria, leading to the mature 20K cyclophilin protein in the matrix[14].

To analyse whether the mutations leading to CsA-resistance affected the levels of cylophilin, we performed western blot assays[23] with cyclophilin-specific antibodies[14], as well as CsA-binding assays[8,9,11] (Fig. 1). Both cytosolic and mitochondrial fractions of wild-type strain and the CsA-resistant segregants in wild-type background (to ensure that only the *csr-1* gene was affected), were analysed. Cyclophilin was present in both the cytosolic and mitochondrial fractions of the wild-type strain 74A and the spontaneous mutant B60. None of the other mutants, however, contained immunodetectable cyclophilin in either the cytosol or the mitochondria (Fig. 1*a*).

In all the mutants we tested (including B60), no significant CsA-binding activity was detectable in the cytosolic fractions (Fig. 1*b*), in contrast to wild-type cytosol where normal binding was observed[14]. In mitochondrial extracts of all mutant strains (prepared by lysing isolated mitochondria in 1.8% *N*-octylglucoside and centrifugation[14]), specific CsA-binding activity was reduced to 10–30% of that seen with wild-type mitochondrial extracts[14]. The residual binding activity present in the mutant mitochondria may be due to another CsA-binding component, different from cyclophilin.

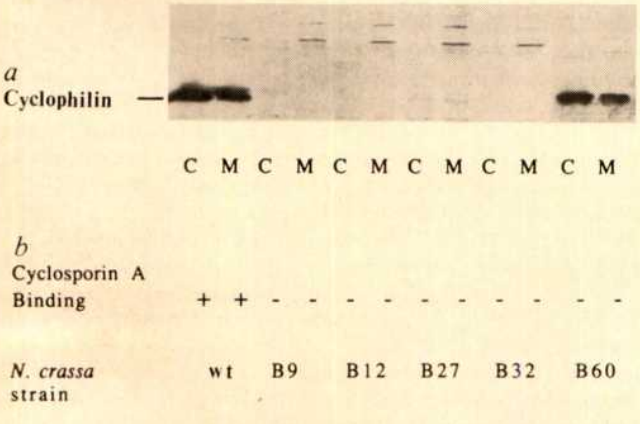

FIG. 1 Western blot analysis of cyclophilin (20K) (*a*) and analysis of CsA-binding (*b*) of cytosolic and mitochondrial fractions of *N. crassa* wild-type and CsA-resistant mutants.

METHODS. *a*, *N. crassa* 74A wild-type (wt) and CsA-resistant mutants (B9, B12, B27, B32, B60) were fractionated into cytosol (C) and mitochondria (M) (refs 14, 26). Protein (100 μg) from each fraction was electrophoresed on a 15% SDS-polyacrylamide gel, transferred to nitrocellulose paper[23], and immunodecorated with polyclonal antibodies raised against *N. crassa* cyclophilin[14]. Bound antibodies were visualized using peroxidase coupled to antibodies against rabbit IgG. *b*, Cytosolic fractions of the different strains were assayed for CsA binding[8,9,11,14]. With all mutants tested, specific binding of $[^3\mathrm{H}]$CsA was less than 5–10% of that of wild-type cytosol[14]. Isolated mitochondria were lysed in 1.8% *N*-octylglucoside, centrifuged[14] and the detergent extracts tested for the ability to bind $[^3\mathrm{H}]$CsA in a LH-20 assay[8,9,11,14]. In the mitochondrial extracts of the different mutants, specific binding of $[^3\mathrm{H}]$CsA was significantly reduced (10–30% of specific binding of wild-type mitochondrial extracts[14]).

Taken together, CsA-resistant mutants of *N. crassa* that are affected in the gene *csr-1* (which is probably the gene coding for cyclophilin) had either completely lost cyclophilin in both cytosol and mitochondria, or, if the protein was still present (as in mutant B60), it had lost its CsA-binding ability. These data indicate that either cytosolic or mitochondrial cyclophilin, or both, is the mediator of CsA action in *N. crassa*.

We performed similar experiments in the yeast *S. cerevisiae*, which was previously reported to be insensitive to CsA (ref. 1). We found that CsA-sensitivity seems to be coupled to a Petite phenotype, and is most probably due to alterations in the cell wall[24] which lead to increased permeability to the hydrophobic drug. Forty-eight different laboratory strains of *S. cerevisiae* were tested for CsA-sensitivity; only two, both with the Petite phenotype, were found to be sensitive to $100\,\mu g\,ml^{-1}$ CsA. CsA-sensitive mutants could easily be selected from CsA-resistant wild-type strains by screening for spontaneous Petite phenotypes.

Starting with the CsA-sensitive ρ^0 strain IL 993/5c (ref. 25) (wild type (wt); Fig. 2), eight independent, spontaneous CsA-resistant mutants were isolated (strains 1–8; Fig. 2). Growth tests on nonfermentable carbon sources such as glycerol, confirmed that they did not represent ρ^+ revertants. All CsA-resistant yeast mutants showed no significant CsA-binding activity in the cytosolic fractions (Fig. 2*b*). In addition, two of these mutants (mutants 7 and 8; Fig. 2*a*) contained no immunodetectable cyclophilin. Yeast cyclophilin has an apparent relative molecular mass of 17K, and is recognized by antibodies raised against either *N. crassa* cyclophilin[14] or isolated yeast cyclophilin. We have cloned and sequenced both a full-length complementary DNA and the gene coding for the cytosolic form of *S. cerevisiae* cyclophilin (K. Dietmeier and M. T., manuscript in preparation).

Our results demonstrate that cyclophilin is a cellular target of CsA. Both in *N. crassa* and in yeast the cytotoxic action of CsA is mediated by cyclophilin. In the absence of cyclophilin (or in the presence of a mutated cyclophilin that has lost its CsA-binding activity), CsA does not have any toxic effect.

These findings raise several intriguing questions concerning both the physiological role of cyclophilin and the mechanism

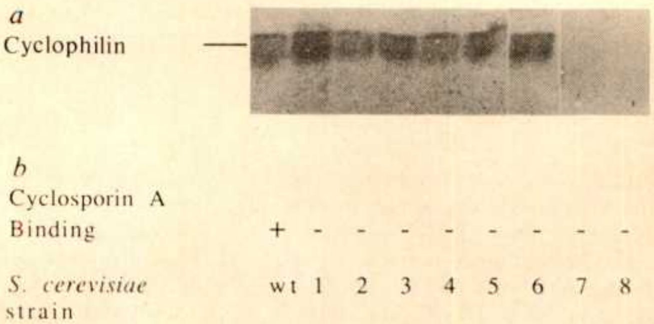

FIG. 2 Western blot analysis of cyclophilin (17K) (*a*) and analysis of CsA-binding (*b*) of cytosolic fractions of *S. cerevisiae* wild-type and spontaneous CsA-resistant mutants.

METHODS. *a*, Wild-type (wt) strain IL 993/5c (ref. 24) was grown at 30 °C in YPD medium[32], 1% ethanol, 0.1% Tween 80; eight independent spontaneous mutants (strains 1–8) were grown under identical conditions, except that the medium contained $50\,\mu g\,ml^{-1}$ CsA. Zymolyase-spheroplasts were lysed and cytosolic fractions prepared[32] and analysed as in Fig. 1. *b*, Cytosolic fractions of the different strains were assayed for CsA-binding[8,9,11,14]. With all mutants tested (strains 1–8), specific binding of $[^3\mathrm{H}]$CsA was less than 5–10% of that of wild-type cytosol[14].

of CsA action. Cyclophilin is a highly conserved protein in all eukaryotes analysed so far[9,12-14]. How can *N. crassa* and yeast cells survive without showing any detectable phenotype in the absence of cyclophilin?

Recent work[16,17] has demonstrated the identity of cyclophilin to peptidyl-prolyl *cis-trans* isomerase (PPIase)[18,19]. Both isolated *N. crassa* and yeast wild-type cyclophilins were found to possess PPIase-activity similar to the human and bovine enzymes (S. Mayer, F. X. Schmid, D. W. Nicholson and M.T., manuscript in preparation). Furthermore, PPIase-activity measured in cytosolic and mitochondrial fractions of *N. crassa* mutants that lack cyclophilin, indicate the presence of additional PPIase-activities in both the cytosol and mitochondria. In a Southern blot analysis of *N. crassa* DNA, using low-stringency conditions, we have found two bands that cross-hydridize with a cyclophilin probe, and which may correspond to the additional PPIase-activities. The presence of these additional PPIase-activities could explain why a complete loss of cyclophilin does not lead to cell death.

Why does CsA stop growth of wild-type cells but not of cyclophilin-deficient mutant cells? We propose that binding of CsA to cyclophilin leads to the formation of a complex which then interacts with another, unidentified cellular component. This interaction must be lethal to the cell. Other explanations are possible, although less likely. For example, cyclosporin A could be modified by cyclophilin and the derivative could be lethal to the cells.

It is tempting to speculate that cyclophilin may be involved in the unfolding/refolding of newly synthesized proteins, in particular of those which have to traverse the various cellular membranes[26-29]. In this respect it may be relevant that a cyclophilin-related protein, namely the product of the *ninaA* gene of *Drosophila melanogaster*, has been suggested to be involved in the folding of rhodopsin *in vivo*[30,31].

Note added in proof: We have learned that T. Chang, B. Weisblum and R. L. Metzenberg (personal communication) have also identified a *N. crassa* gene for cyclosporin A resistance on linkage group I, left of *cyh-1* (1%). □

SELF-INCOMPATIBILITY in flowering plants is often controlled by a single nuclear gene (the *S*-gene) having several alleles[1]. This gene prevents fertilization by self-pollen or by pollen bearing either of the two *S*-alleles expressed in the style. Sequence analysis shows that three alleles of the *S* gene of *Nicotiana alata* encode style glycoproteins[2,3] with regions of defined homology. Two of the homologous regions also show precise homology with ribonucleases T_2 (ref. 4) and Rh (ref. 5). We report here that glycoproteins corresponding to the S_1, S_2, S_3, S_6 and S_7 alleles isolated from style extracts of *N. alata*[6] are ribonucleases. These style *S*-gene-encoded glycoproteins account for most of the ribonuclease activity recovered from style extracts. The ribonuclease specific activity of style extracts of the self-incompatible species *N. alata* is 100–1,000-fold higher than that of the related self-compatible species *N. tabacum*. These observations implicate ribonuclease activity in the mechanism of gametophytic self-incompatibility.

Cloned complementary DNAs corresponding to the S_2-, S_3- and S_6-allelic glycoproteins[6] have recently been isolated[2,3]. The primary amino-acid sequences of three *S*-glycoproteins show some regions that are perfectly conserved and other regions that are less homologous[3]. Sequence analysis reveals significant homology between the *S*-glycoproteins and the extracellular ribonucleases (RNases) T_2 of *Aspergillus oryzae*[4] and Rh of *Rhizopus niveus*[5] (Fig. 1). The two longest regions of homology, residues 67–72 and 138–142 (Fig. 1) include His 67 and His 139 which are implicated in RNase T_2 catalysis[4]. It is significant that these homologous regions are also conserved among the three *S*-glycoproteins. In total, of the 122 amino acids perfectly conserved among the three *S*-glycoproteins, 30 are aligned with identical amino acids in the fungal RNases and another 22 are aligned with closely related amino acids. The positions of 5 out of 10 cysteine residues are conserved between the *S*-glycoproteins and the RNases. Two of these cysteine residues, 86 and 143, located in the vicinity of the proposed RNase active site, form a disulphide bond in RNase T_2 (ref. 4). These sequence similarities indicate a close structural relationship between the active-site domain of the two secreted fungal RNases and the homologous region of the *S*-glycoproteins. This homology prompted us to investigate the RNase activity of the *S*-glycoproteins.

The *S*-glycoproteins can be purified from style extracts by a procedure involving ammonium-sulphate fractionation and cation-exchange chromatography[6]. The *S*-glycoproteins isolated by this method behave as a single species on SDS-PAGE or reverse-phase HPLC; N-terminal sequencing confirms their identity with the proteins predicted from the cloned cDNAs[6]. The association of particular *S*-glycoproteins with the corresponding *S* allele is further supported by data which show that, in every case examined, the elution profile of proteins resolved by cation-exchange chromatography correctly predicts the genotype of the source material. Also, these isolated *S*-glycoproteins are active as inhibitors of *in vitro* pollen tube growth[7]. Initially, three *S*-glycoprotein preparations isolated from style extracts of plants homozygous for the S_1, S_2 and S_6 alleles had RNase activities when assayed by the perchloric acid precipitation method[8] (data not shown). The RNase activity of the isolated S_2-glycoprotein had a pH optimum of 7.0, a temperature optimum of 50 °C, and was not affected by Ca^{2+}, Mn^{2+}, Zn^{2+}, EDTA (1 mM) or Mg^{2+} (10 mM). Denatured DNA was not hydrolysed by the S_2-glycoprotein.

In two experiments (Fig. 2*a*, *b*), extracts from equal numbers of styles homozygous for two different alleles (S_3 plus S_7; S_1 plus S_6) were mixed and analysed. In all cases, RNase activity coeluted with the individual *S*-glycoproteins and was *S*-allele specific (Fig. 2, compare *b* and *c*). Given that the different *S*-glycoproteins are clearly resolved by ion-exchange chromatography and that the RNase activity coelutes with the *S*-glycoproteins, the ribonuclease activity must be an inherent component of the *S*-glycoproteins. Furthermore, the RNase specific activity of the purified *S*-glycoproteins varies from 170 (S_1-glycoprotein) to 2,200 (S_7-glycoprotein) A_{260} units min^{-1} mg^{-1}, values similar to the specific activity of purified RNase T_2 (3,900 A_{260} units min^{-1} mg^{-1}) when measured under the same conditions. The origin and possible biological significance of the variation in *S*-glycoprotein RNase specific activity, which accounts for the difference in the sizes of the RNase activity peaks (compare the S_6- and S_1-glycoprotein peaks in Fig. 2*b*) associated with the various *S*-glycoproteins, is now being investigated. This variation could be due to the differential stability of the RNase activities under purification conditions, which were designed primarily to optimize separation of the *S* allele-specific glycoproteins.

Because most of the RNase activity in crude style extracts was applied to the cation-exchange column (Fig. 2 legend) the percentage of the RNase activity recovered from the column was a good indicator of the proportion of the total style activity that is attributable to the *S*-glycoproteins. Of the recovered RNase activity, 40% (Fig. 2*c*) to 86% (Fig. 2*b*) can be attributed to *S*-glycoproteins. *N. alata* style extracts also contain an additional minor RNase activity (X in Fig. 2) which does not cofractionate with the *S*-glycoproteins on chromatography and is therefore not an allele-specific RNase.

TABLE 1 Ribonuclease specific activities

Style extracts were prepared as described in Fig. 2 legend, but were not ammonium-sulphate fractionated. Pollen extracts were prepared similarly, except that pollen was disrupted by brief sonication. Ribonuclease activity was assayed at 37 °C according to Brown and Ho[8]. Protein was determined according to Bradford[10] using BSA as a standard. Abbreviation: cv, cultivar.

* A_{260} units released per min per mg.

This inherent association of RNase activity with the *S*-glycoproteins indicates a way in which they could function. The *S*-glycoproteins are secreted into the style mucilage, which separates the files of transmitting tissue cells and provides a matrix through which pollen tubes grow towards the ovary[3,9]. The style *S*-glycoprotein could penetrate the pollen tube and degrade RNA in the cytoplasm. This would interfere with protein synthesis, and could account for the characteristic slowing of self-pollen tube growth.

The nature of gametophytic self-incompatibility indicates that the *S*-gene must be expressed in the pollen as well as in the style[1]. Relative to style extracts, only trace amounts of RNase activity were detected in pollen extracts (Table 1) and in pollen germinated *in vitro* (B.A.M., unpublished results) indicating that, if it is an RNase, the product of the *S* gene in pollen is not highly expressed. Indeed, it now seems very unlikely that the *S*-gene products in the *N. alata* pollen and style are identical, yet it is clear that they must share an allelic specificity for recognition to occur[1]. It is possible that the specificity controls the access of style RNase to the putative substrate within the pollen tube. Alternatively, the specificity could reside in the

FIG. 1 Alignment of the amino-acid sequences (single-letter code) of the *S*-glycoproteins[6] with those of the ribonucleases Rh (ref. 4, and F.S., unpublished results) and T_2 (ref. 5) were made using the program CLUSTAL[11]. Gaps (-) have been introduced to optimize the alignment. The presumptive active-site histidine residues are marked by an asterisk. Boxed residues are identical among all five sequences, whereas similar residues (those belonging to the groups Asp, Glu, Asn and Gln (DENQ), Ser and Thr (ST), Ile, Leu, Met and Val (ILMV), and Phe, Trp and Thr (FWY) are marked by a circle (○). The amino-acid sequences of the S_2-, S_3- and S_6-glycoproteins of *N. alata* are from Anderson *et al.*[3]. The sequences of the ribonucleases Rh of *R. niveus* and T_2 of *A. oryzae* are from Horiuchi *et al.*[5] and Kawata *et al.*[4], respectively. The significance of the alignments was assessed with the ALIGN program[12]. With the mutation data matrix (250 PAMs), a bias of +6, and a gap penalty of 9, the alignments of the *S*-glycoprotein sequences with the RNase sequences had scores of 7.9–10.6 s.d. above the mean scores from 100 alignments of the randomized sequences. For comparison, the alignments of the *S*-glycoprotein sequences with the same parameters, had scores of 35.0–41.3 s.d. units. The alignment of the T_2 and Rh RNases gave a score of 21.8 s.d. units.

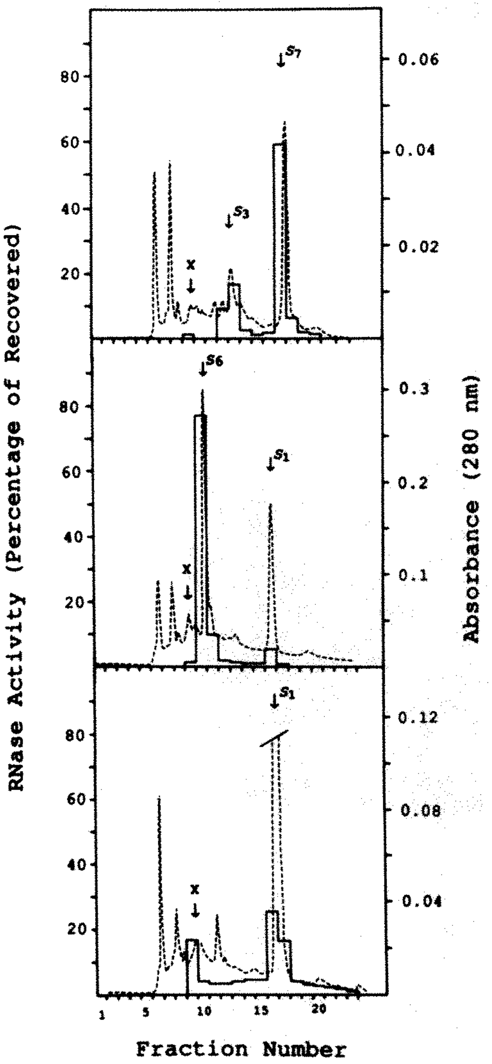

FIG. 2 Elution profiles of style extracts from mature flowers of *N. alata*. Extracts from styles of plants homozygous for the S_1-, S_3-, S_6- and S_7-alleles were prepared and fractionated by cation-exchange chromatography as previously described[6]. The elution profile was continuously monitored for absorbance at 280 nm (dotted line) and each fraction was assayed for ribonuclease activity[8] (solid line). *a*, Fractionation of an extract of a mixture of five styles, each of flowers homozygous for the S_3- and S_7-alleles. *b*, Fractionation of an extract of a mixture of 10 styles each of flowers homozygous for the S_6- and S_1-alleles. *c*, Fractionation of an extract from 20 styles of flowers homozygous for the S_1-allele. The elution position of each of the *S*-glycoproteins[6] is indicated. In each case, a major peak of ribonuclease activity co-fractionated with the *S*-glycoproteins on chromatography. A second peak of ribonuclease activity, not associated with the *S*-glycoproteins, is indicated by X. The ammonium-sulphate fractionation and desalting steps seem to cause no more than a 20% loss of activity. Thus 80% of the RNase activity in crude style extracts was subjected to cation-exchange chromatography. Total recovered activities were 64, 172 and 43 units in *a*, *b* and *c*, respectively. Conditions for isolation of the glycoproteins was as published[6] without further optimization for recovery of enzyme activity.

METHODS. Styles from defined *S*-genotypes of *N. alata*[2] were collected from plants maintained in the glasshouse. Extracts were prepared by homogenization (200 mg ml^{-1}) in 100 mM Tris-HCl butter, pH 7.8, 14 mM 2-mercaptoethanol containing 20 mg ml^{-1} Polyclar AT and 20 mg ml^{-1} Dowex 1×2 Cl (ref. 6). *S*-glycoprotein recovered from the extract after ammonium-sulphate fractionation (50–95%) was desalted into 50 mM sodium acetate, pH 5, by passage over a Sephadex G-25 column (Pharmacia) and applied to a Mono-S (HR 5/5) cation-exchange (Pharmacia) column. The column was developed with a linear NaCl gradient (0–500 mM at 1 ml min^{-1}) at room temperature (~18 °C). The eluate was continuously monitored for absorbance at 280 nm (dotted line). An aliquot of each 1-ml fraction was assayed for RNase activity essentially as previously described[8], except that the reactions were carried out in 100 mM imidizole-HCl, pH 7, 50 mM KCl at 37 °C for 30 min using torula yeast RNA (4 mg ml^{-1}; Sigma) as substrate. To reduce endogenous RNase activity, the substrate was repeatedly extracted with phenol:chloroform:isoamyl alcohol (25:24:1)[13], subjected to LiCl precipitation[14] and finally precipitated as the ammonium salt.

inhibition of the style RNase by the gametophyte.

This mechanism of inhibition of pollen tube growth is compatible with some observations on unilateral interspecific incompatibility[1]. One type of unilateral incompatibility is exemplified by reciprocal crosses between the self-incompatible species *N. alata* and the self-compatible species *N. tabacum*. Styles of all *S*-genotypes of *N. alata* have high RNase activity (Table 1) and support only limited growth of pollen tubes from *N. tabacum*. By contrast, styles from *N. tabacum* allow growth of pollen tubes from all *S*-genotypes of *N. alata*, leading to seed-set. It is significant that styles from *N. tabacum* do not contain an *S*-glycoprotein-like component and have relatively low total RNase activity (Table 1). The high level of RNase associated with the style *S*-glycoproteins could contribute to the rejection of *N. tabacum* pollen by mature *N. alata* styles (that is *N. tabacum* pollen could lack the ability to reject or inhibit the *S*-glycoprotein RNase). Conversely, *N. tabacum* could accept *N. alata* pollen by virtue of the absence of style *S*-glycoprotein RNase. Preliminary findings consistent with this view are that another gametophytic self-incompatible plant within the solanaceae *Lycopersicon peruvianum* has a high level of style RNase, whereas a closely related self-compatible accession has a low level of RNase activity (I. Lewis and B.A.M.-C., unpublished results). Also, bovine pancreatic RNase A is a nonspecific inhibitor of *in vitro* pollen tube growth, indicating that pollen tubes are susceptible to extracellular RNases (M. Lush, unpublished observation).

The results described here demonstrate that the *S*-glycoproteins have inherent RNase activity and indicate that this activity is involved in the inhibition of pollen tube growth in the self-incompatibility reaction of *N. alata*. This re-orientates our thinking about the function of the *S*-glycoproteins away from the traditional receptor–ligand model[1] to models based on cytotoxic enzyme activity. Indeed, these observations lead to a more generalized hypothesis for inhibition of pollen tube growth based on uptake by the gametophyte of a cytotoxic agent secreted by the style. In this model, the pollen *S*-gene product would enable non-self pollen to reject or inactivate the style cytotoxin, whereas pollen lacking an *S*-allele or bearing an *S*-allele identical to one present in the style would be unable to perform this function. ☐

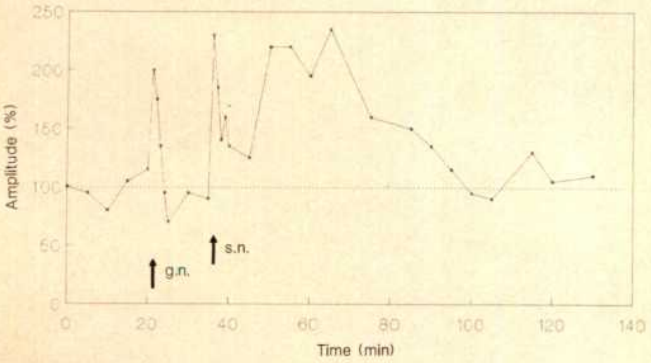
ERRATUM

Changes in spinal cord reflexes after cross-anastomosis of cutaneous and muscle nerves in the adult rat

Stephen B. McMahon & Patrick D. Wall

Nature **342**, 272–274 (1989)

OWING to editorial errors, an incorrectly labelled version of Fig. 2 was used in this manuscript, with the labels for the sural nerve (s.n.) and gastrocnemius nerve (g.n.) transposed. The figure is shown in its correct form below. ☐



CORRECTIONS

An optical yield that increases with temperature in a photochemically induced enantiomeric isomerization

Yoshihisa Inoue, Taizo Yokoyama, Noritsugu Yamasaki & Akira Tai

Nature **341**, 225–226 (1989)

IT has come to *Nature's* attention that this paper substantially duplicates a paper from the same authors in the *Journal of the American Chemical Society* **111**, 6480–6482 (1989). *Nature* was not made aware of the latter paper by the authors although it was submitted first. ☐

The winter solstice phenomenon at Newgrange, Ireland: accident or design?

T. P. Ray

Nature **337**, 343 (1989)

OWING to circumstances beyond *Nature*'s control, cooperation on the above project, an account of which appeared in our issue of 26 January 1989, was not acknowledged. Professor T. P. Ray would now like to correct this omission by stating that the name of T. M. O'Brien, consultant orthopaedic surgeon in Dublin, should be added to his own. Both were simultaneously engaged on research at Newgrange. Mr. O'Brien undertook the photographic and architectural surveys, Professor Ray the astronomical calculations of the Sun's path into the chamber at the solstitial winter sunrise. ☐

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature's* staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform nonspecialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

***Submission.** All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

CANCELLATIONS MUST BE RECEIVED NO LATER THAN 5PM ON THURSDAYS PRIOR TO ISSUE DATE.

UNIVERSITY OF CAPE TOWN

Lecturer:

Dept of Chemistry

Applications are invited for the above post.

No particular specialisation is required, but the successful applicant will hold a PhD degree, have demonstrated a research capability with a significant publication record and have proven ability and experience in lecturing undergraduate classes.

A negotiable salary package includes attractive staff benefits such as medical aid, a pension scheme and a housing subsidy in certain circumstances. Further details concerning remuneration will be sent to applicants on request.

Applicants should submit a full curriculum vitae and the names and addresses of three referees, not later than 30 January 1990, to the Appointments Officer (Ref: NB), University of Cape Town, Rondebosch 7700, Republic of South Africa (tel: (21) 650-2192; fax: (21) 650-2138). Further information may be obtained from the above, or from the Secretary, SA Universities Office, 2nd Floor, 16 Charles II Street, London SWIY 4QU.

The policy and practice of the University of Cape Town is to oppose discrimination on grounds of gender, race or creed in any sphere of university life. UCT has consistently protested, and continues to protest, against apartheid laws and practices and is committed to a just future for our country. Information on this is available on request.

Biology Department Scientific Staff Vacancy

PLANT SCIENTIST

Applications are invited for a staff position in the area of plant cell biology, structural biology, molecular biology or genetics. Applicants should have a Ph.D. or equivalent degree and relevant postdoctoral training. The selected candidate will be expected to develop an independent and creative program on a biologically important topic relevant to plants.

- The Biology Department has strong programs in molecular genetics, structural biology, DNA damage and repair, virology, and plant molecular biology.
- Offer includes excellent start up funding and facilities, a competitive salary, and a comprehensive benefits package.

This is a reopened search. New respondents should submit a curriculum vitae, a list of at least three professional references, and a statement of research interests to: Dr. G. Hind, Biology Department, Brookhaven National Laboratory, Associated Universities, Inc., Upton, L.I., New York 11973. Deadline for applications is February 26, 1990. Equal opportunity employer, M/F.

Scientist Research and Development Coagulation

The ideal candidate will have a Ph.D. in a haemostasis/thrombosis related subject. Experience in protein purification would be a distinct advantage.

You would work in a small research team in the development of chromogenic and immunological based assays for clotting factors.

Please send your C.V. to Mrs. R. Sutter, Baxte Dade AG, Bonnstrasse 9, CH-3186 Düdingen/Switzerland, phone (Int. 41) 37/43 87 51. (W6857)A

Baxter Dade AG

Baxter

UNIVERSITY OF BRISTOL
DEPARTMENT OF PHYSIOLOGY
RESEARCH ASSISTANT 1B

Recent graduate in physiology or related science required to assist with experiments on Ca++/H+ interactions in voltage-clamped snail neurones. The project will be funded by a new 3-year MRC project grant to Professor Roger Thomas, and will involve both fluorescent dye and microelectrode measurement of ion activities. The assistant will be expected to register for a higher degree and help with departmental teaching.

Initial salary £9,816 with annual increments, USS, etc. Position available from April 1990 onwards.

Informal enquiries to 0272 303474 or 303473.

For further details telephone Bristol 303136 (ansaphone after 5.00 p.m.) or write to the **Personnel Office, Senate House, Bristol BS8 1TH.** Please quote reference A911.

Applications in the form of a detailed C.V. with names, addresses and telephone numbers of 3 referees to the Personnel Office by 26th January, 1990. (2349)A

CANGENE CORPORATION

Cangene Corporation, The Canadian Genetic Engineering Company, is currently moving into commercialization of a number of biopharmaceuticals through recombinant DNA technology. The following opportunity is available for an individual of proven accomplishment.

Manager, Quality Control

This position involves the development and implementation of Quality Control procedures for the fermentation, purification, formulation and packaging of biopharmaceuticals for human medical applications.

A relevant advanced degree and at least three years of experience in the quality control of recombinant proteins is required. Managerial experience is essential, as is familiarity with FDA, GMP and Safety regulations.

A background in one or more of protein biochemistry, microbiology and immunology is preferred.

Cangene Corporation, located near Toronto, one of North America's most livable cities, is financed by a number of Canada's largest commercial enterprises. The Company offers an attractive compensation package including moving expenses, and the opportunity to work in a creative, goal-oriented atmosphere.

Candidates are invited to submit, in strictest confidence, a curriculum vitae, with at least two references, and quoting file #1124 to:

MANAGER, HUMAN RESOURCES

CANGENE CORPORATION
3403 American Drive, MISSISSAUGA, Ontario L4V 1T4

(NW4751)A

CANGENE CORPORATION

Project Leader

Cangene Corporation, The Canadian Genetic Engineering Company, has a new opening for a Project Leader to plan, implement, and direct the work leading to the solution of various research goals pertaining to the genetics of Streptomyces.

Qualifications

The successful candidate will have a Ph.D. degree with substaintial post-graduate experience in the application of molecular biology techniques to the genetics and microbiology of Streptomyces. Extensive background in techniques such as mutagenesis of Streptomyces, screening and selection of mutants, genetic disruption, protoplast fusion, and genetic mapping are essential for this position.

Cangene Corporation, located near Toronto, one of North America's most livable cities, is financed by a number of Canada's largest commercial enterprises. The Company offers an attractive compensation package including moving expenses, and the opportunity to work in a highly creative, goal-oriented atmosphere.

Candidates are invited to submit, in strictest confidence and quoting file #1109, their curriculum vitae and the names of three references to:

MANAGER, HUMAN RESOURCES

CANGENE CORPORATION

NATIONAL UNIVERSITY OF SINGAPORE
DEPARTMENT OF ORTHOPAEDIC SURGERY

RESEARCH FELLOW

Applications are invited for appointment as Research Fellow in the **Department of Orthopaedic Surgery.** Candidates should possess a PhD degree in Biochemistry and preferably have some research experience in biochemistry of soft tissues, cartilage and bone, quantitative morphometry and immunochemical work.

The successful candidate will be required to assist in the running of the biochemistry laboratory in the Department. The appointment may be for up to three years at a time.

Gross monthly emoluments will range from S$3739 to $5350. (STG£1 = S$3.08 approx.) The commencing salary is dependent upon the qualifications and experience of the appointee.

Leave and medical benefits will be provided. Depending on the type of contract offered, other benefits may include: provident fund benefits or an end-of-contract gratuity, a settling-in allowance of S$1,000 or S$2,000, subsidised housing at nominal rentals ranging from S$100 to S$216 p.m., education allowance for up to three children subject to a maximum of S$10,000 per annum per child, passage assistance and baggage allowance for the transportation of personal effects to Singapore.

Candidates should write to the **Director, Personnel Department, National University of Singapore, 10 Kent Ridge Crescent, Singapore 0511,** giving their curriculum vitae and the names and addresses of three referees who can comment on their research ability and/or professional competence.

Enquiries may also be sent through BITNET to: **PERSDEPT @ NUSVM,** or through **Telefax: (65) 7783948.** (W6858)A

INSTITUTE OF VIROLOGY & ENVIRONMENTAL MICROBIOLOGY

Oxford

Post-Doctoral Vacancies

1. Lyme Disease: A post-doctoral research assistant (Higher Scientific Officer) is required to develop diagnostic probes and reagents for detecting infections by Borrelia burgdorferi, the aetiologic agent of Lyme borreliosis. Vaccine development will also be undertaken. Experience in molecular biology and in handling spirochaetes will be an asset.
2. Virus Replication: A senior post-doctoral researcher (Higher or Senior Scientific Officer) is required to work on the mechanism of RNA virus replication.

Starting salary will be in the range of £10,678–£14,909 (HSO scale) and £13,254–£18,864 (SSO scale) depending on experience and qualifications. Staff of the Council are not Civil Servants but their pay and conditions are similar to those of the Civil Service. There is a non-contributory pension scheme.

Application forms are available from the **Administration Officer, Institute of Virology and Environmental Microbiology, Mansfield Road, Oxford, OX1 3SR.**

The Natural Environmental Research Council is an equal opportunity employer. (2346)A

THE UNIVERSITY OF CALIFORNIA AT SAN DIEGO
DEPARTMENT OF BIOLOGY

FACULTY POSITION

The Department of Biology of the University of California, San Diego, invites applications for a tenure-track assistant professor position in mammalian molecular biology, animal virology or related areas.

Salary will be commensurate with level of appointment and based on the UC published salary scale. The successful candidate is expected to develop a vigorous research program in one of these rapidly-moving areas and participate in the department's undergraduate and graduate teaching program. A Ph.D. and several years of productive postdoctoral research training are required.

Please submit curriculum vitae, a statement of professional goals and research interests, and names of three references by February 15, 1990.

The University of California, San Diego, is an equal opportunity/affirmative action employer. (NW4742)A

DSIR

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

DIRECTOR OF NEW DIVISION CONCERNED WITH LAND AND ECOLOGICAL SERVICES

As part of the restructuring of the DSIR into larger operating units, on 1 April 1989 the DSIR Divisions of Botany, Ecology and Land and Soil Sciences will be regrouped into one large land resources Division, as yet to be named.

The new Division will consist of some 230 staff presently located mainly in the Hutt Valley, Christchurch and Palmerston North as well as at a number of smaller offices. The annual budget is presently $17.8M. The Division will undertake research and consultancy on land and soil characteristics and processes, botany and ecology and the application of this knowledge to practical problems, both in New Zealand and overseas.

The Director will be located in the Wellington area and will be responsible to the Director-General for all aspects of the management of the Division and for ensuring that the DSIR provides the Government with timely and effective scientific advice on matters concerning soil and land.

The successful applicant will have high qualifications and scientific attainment in land and soil science. Demonstrated leadership qualities with good administrative and financial management skills at a senior level are essential.

The conditions of employment and a substantial remuneration package commensurate with the importance of the position will be negotiated with the successful applicant.

Enquiries should be addressed:

Dr M.E.U. Taylor, DSIR, Head Office,
P O Box 1578, Wellington, NEW ZEALAND

Application should be made to the Director-General DSIR with a full curriculum vitae. Closing date for applications is 13 January 1990.

(W6853)A

Experimental Nuclear Physicist

There is a vacancy for an experimental physicist to join the Nuclear Physics Division. The experimental group is involved in carrying out and supporting a broadly based research programme using a 20MV Tandem.

The successful applicant will be expected to engage in research in nuclear physics and to play an active role in initiating and developing new programmes. Other duties will involve work on the design and development of major equipment through to commissioning, operation and maintenance. As a member of the in-house team of scientists he/she will be expected to provide expertise in the methods of experimental nuclear physics and to aid and direct the technical and scientific support staff in operating the Nuclear Structure Facility and for diagnosing problems as they arise.

Applicants should have a good honours degree in an appropriate discipline or equivalent with a period of postgraduate experience. A PhD degree in nuclear physics and a period of post doctoral experience in experimental nuclear physics would be an advantage. The appointment will be in the grade of Higher Scientific Officer with a salary range of £10,678 to £14,909, starting salary depending on qualifications and experience. Further increments are available depending on performance. The superannuation scheme is non-contributory.

CLOSING DATE: 12 January 1990

For further information please contact Dr. J. S. Lilley on (0925) 603558.

Application forms may be obtained quoting reference DL/141 from: The Personnel Officer, Science and Engineering Research Council, Daresbury, Warrington, WA4 4AD. Tel: (0925) 603467 (24 hour answering service).

(2356)A

SCIENCE & ENGINEERING RESEARCH COUNCIL

RESEARCH OPPORTUNITIES

The Commonwealth Scientific and Industrial Research Organisation (CSIRO) is a government research body with over 7000 staff, divided into 32 Divisions, each addressing specific industry sectors. The Division of Geomechanics is Australia's largest geomechanics research group, and undertakes research to increase the productivity, safety, and international competitiveness of the Australian mining, hydrocarbon, and civil engineering industries. The Divisional HQ is being located in new laboratories in Brisbane, Queensland, Australia.

RESEARCH ENGINEER

(Geotechnical)

To lead a multidisciplinary team developing new geotechnical applications in surface and underground coal mines and tunnels. Activities include new geomechanical analyses, development and implementation of field instrumentation, data analyses, laboratory testing and modelling for a variety of geotechnical projects.

RESEARCH GEOLOGIST

(Structural Modelling)

To study geological factors controlling the formation and exploitation of commercial coal seam methane deposits, and techniques to identify exploration targets. Development of 3D modelling techniques for the geology, structure, mechanical, and hydrological properties of exploration and production sites, in a graphic workstation/supercomputer environment.

RESEARCH ENGINEER/GEOLOGIST

(**In situ** Mining Technology)

To implement and lead research and development projects in **in situ** solution mining, in collaboration with mining companies and other interested parties. Research areas could include the hydrology of ore bodies, fluid flow/solution characteristics of ore, mechanics of **in situ** leaching, and enhancement of leaching performance.

RESEARCH ENGINEER

(Reservoir Engineering — Well Testing)

To undertake development of new well testing tools for the evaluation of the multi-phase (gas - water) flow characteristics of coal seams, and, as part of a skilled team, to organise and supervise industrial applications of new well testing technology - including data analysis.

Qualifications: PhD or equivalent in engineering, geology or related fields.

Tenure: Indefinite, with Australian Government superannuation benefits.

Salary: $A31525 to $53621

Further information: Including job descriptions and selection criteria, can be obtained by telephoning Mrs Elizabeth Mills in the London Office of the Agent-General for Queensland on(1)836 1333.

Applications: Quoting the names of at least two professional referees, should be sent to:

The Officer in Charge
CSIRO Division of Geomechanics
PO Box 63
St Lucia Qld 4067
Australia
by 19 January 1990.

THE UNIVERSITY OF ARIZONA

FACULTY POSITION IN X-RAY CRYSTALLOGRAPHY

Applications are invited for a tenure-track position in x-ray crystallography for macromolecular systems. Although there is a preference for candidates at the Assistant Professor level, applicants at more senior levels will be considered. This is part of an ongoing effort to develop an exceptionally strong program in structural biology and biophysics. We have recently added three NMR spectroscopists and an x-ray crystallographer to this program, and plan to fill additional positions in the next 1-2 years. Applicants will be expected to carry out a vigorous research program with ample opportunities for collaboration, as well as to contribute to our graduate and undergraduate teaching program. An excellent crystallographic facility is available, with fund in place for the purchase of additional equipment. Applicants should submit curriculum vitae, representative reprints, a short statement of research plans, and have at least three letters of reference sent to: **Dr. William Montfort, Co-chair, Search Committee, Department of Biochemistry, Biosciences West, The University of Arizona, Tucson, AZ 85721.**

Review of applications will begin January 15, 1990, but the position will remain open until filled.

Women and minorities are urged to apply.

An Equal Opportunity/Affirmative Action/Title IX/ Section 504 Employer.

(NW4762)A

THE UNIVERSITY OF CALIFORNIA AT SAN DIEGO
DEPARTMENT OF BIOLOGY

FACULTY POSITION IN CELL BIOLOGY

The Department of Biology of the University of California, San Diego, invites applications for a tenure-track assistant professor position in cell biology. Our department covers a broad range of topics including cellular biology, molecular biology, neurobiology, and developmental biology. We are seeking outstanding candidates in the field of cellular biology with emphasis in one of the following areas:

- protein sorting
- signal transduction
- cell-cell interactions
- extracellular matrix
- cell motility

Exceptional applicants in all areas of cellular biology will be considered. Salary will be commensurate with level of appointment and based on UC published salary scale. The successful candidate is expected to develop a vigorous research program and participate in the department's undergraduate and graduate teaching program. *We strongly encourage women and minorities to apply.* Please submit curriculum vitae, names of three references, reprints of publications, and a statement of present and future research plans by February 15, 1990.

Cell Search Committee,
c/o Lynn Grimes,
Department of Biology B-046,
University of California, San Diego,
La Jolla, CA 92093.

The University of California is an Affirmative Action/Equal Opportunity Employer.

(NW4743)A

UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

PROFESSORSHIP

Department of Biological Sciences

Applicants should be experienced scientists of established international reputation in any field of plant science involving relevant areas of microbiology, ecology and genetics.

ASSOCIATE PROFESSORSHIPS/SENIOR LECTURESHIPS/LECTURESHIPS

Department of Biological Sciences

A Biomathematician is required to teach basic statistical procedures and computer usage.

Department of Geology

Applications are sought from economic geologists with practical experience of mineral exploration and/or mining geology.

CONDITIONS OF SERVICE

Salary Scales: Lecturer: Z$22,488–Z$31,692; Senior Lecturer: Z$32,736–Z$35,436; Associate Professor: Z$36,492–Z$37,680; Professor: Z$38,064 (fixed). Appointment on the above scales will be according to qualification and experience.

Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis for an initial period of two years. Short-term contracts may be extended. Applicants should quote reference number ASA/16/11/89 and submit six copies of applications giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees to the Deputy Registrar (Administration), University of Zimbabwe, P O Box MP 167, Mount Pleasant, Harare, Zimbabwe. Telegrams: UNIVERSITY; Telex: 4–152 ZW. Applicants from outside Zimbabwe should also send a copy to the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF, UK**, from whom further details may be obtained.

Closing date for receipt of applications is 18 January 1990.

(W6843)A

TENURE-TRACK FACULTY POSITION

UCR/UCLA PROGRAM IN BIOMEDICAL SCIENCES

CELL BIOLOGY/HISTOLOGY

The UCR/UCLA Program in Biomedical Sciences, which offers an accelerated M.D. curriculum jointly between the University of California, Riverside (UCR) and the University of California, Los Angeles (UCLA) School of Medicine, has a tenure-track faculty position open in the Division of Biomedical Sciences at UCR available July 1, 1990.

Primary responsibilities will be one-half of a 12-week lecture and laboratory course in histology for 24 first-year medical students. Prior medical school teaching experience is strongly preferred. The successful candidate will also be expected to actively participate in graduate student training.

The committee welcomes applications from those with research interests in any area of cell biology who would enjoy working within a multidisciplinary environment.

The prospective level of appointment for candidates, who must possess the Ph.D. and/or M.D. degree, may be at the Assistant, Associate, or Full Professor level. Junior applicants must have postdoctoral research experience and the potential to develop a strong, extramurally funded research program. Senior applicants should have a clearly demonstrable record of research productivity, success in obtaining extramural funding, and demonstrated teaching effectiveness. The University of California is an Affirmative Action/Equal Opportunity employer. The deadline for application is February 15, 1990. Applicants should send a curriculum vitae, representative reprints, a statement of present and future research goals, summary of teaching experience, and arrange to have three letters of recommendation sent to:

Dr Ameae M. Walker
Cell Biology/Histology Search Committee
Division of Biomedical Sciences
University of California
Riverside, California 92521-0121

(NW4744)A

PALEOECOLOGY OF TROPICAL AMERICA

SMITHSONIAN TROPICAL RESEARCH INSTITUTE

The Smithsonian Tropical Research Institute is planning a major expansion of its terrestrial and marine research program in the paleoecology of tropical America. The Institute is a bureau of the Smithsonian Institution and has headquarters in the Republic of Panama. The paleoecology program is documenting the environmental and ecological history of the region over the last 5 million years. We anticipate two new permanent staff positions to begin in October 1990. We invite applicants at any level in the following disciplines: vertebrate paleontology, paleobotany, invertebrate paleontology, micropaleontology, paleooceanography, and paleoclimatology. Annual salary from $30,000 to $59,000 plus benefits and allowances. Level will depend on qualifications. Substantial set-up funds and research support. Screening will begin March 15, 1990 and continue until positions are filled. Applications should include statement of research interests, curriculum vitae, reprints, and names, addresses, and telephone numbers of 5 references. Send to:

Paleoecology Search Committee
Smithsonian Tropical Research Institute
APO Miami 34002-0011, U.S.A.

The Smithsonian Institution is an Equal Opportunity/Affirmative Action Employer, and appointment can be made without regard to nationality. (NW4750)A

RESEARCH ASSISTANT PROFESSOR

The Department of Physiology at Temple University School of Medicine invites applications for a non-tenure track position at the level of Research Assistant Professor. Ph.D. in Physiology and 1–2 years post-doctoral training required. Candidate must have laboratory experience in experimental physiology, protein biochemistry, and handling of radioactive materials. Applicant will be expected to conduct a variety of experiments involving in vivo thrombosis models, which require microvascular surgery. Skill in ligand-receptor binding studies, polyclonal antibody production, human venopuncture, radiolabeling of proteins and protein purification also beneficial. Primary research area will involve the purification of various snake venom peptides and the evaluation of their potential antithrombotic activity in biological systems. Opportunity also available for participation in research focused on the localization of specific binding epitopes for plasma proteins on platelet membrane glycoproteins.

Responsibilities will include the coordination of laboratory activities and the supervision of students and technical personnel as well as independent and collaborative research. Applicant must present evidence of excellent verbal and written communication skills and the ability to obtain research funding. Please send curriculum vitae and three letters of reference to: **Dr. Peter R. Lynch, Chairman,**

Temple University
School of Medicine
Department of Physiology
3420 N. Broad Street
PHILADELPHIA, PA
19140

Faculty Positions Memorial Sloan-Kettering Cancer Center Cell Biology and Genetics Program

The Memorial Sloan-Kettering Cancer Center invites applications for several tenure-track junior and senior faculty positions in the Cell Biology and Genetics Program. This research program is one of four in the institute, and is expanding in the areas of cell cycle control, differentiation, cell structure, intercellular recognition, and morphogenesis. The Cell Biology and Genetics Program is located in a new research building which also houses advanced facilities for protein and nucleic acid microchemistry, transgenic mice, and automated mammalian cell micromanipulation. The members of the Cell Biology and Genetics program faculty are affiliated with the Cell Biology Graduate Program at Cornell University Medical College. The positions offered are highly competitive with regard to start-up funds, laboratory space, salary and housing.

Eligible candidates should have a doctoral degree, postdoctoral experience and demonstrate potential and ability to develop an independent, imaginative research program. Formal applications are invited from junior as well as established investigators. Applications should include a curriculum vitae, a list of publications, a summary of research activities and research plan and three letters of recommendation. Applications should be addressed to: **Dr Joan Massague, c/o Christine Brohme, Box # 135, Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, N.Y. 10021.**

SIMON FRASER UNIVERSITY
CHAIR OF THE DEPARTMENT OF BIOLOGICAL SCIENCES

Applications and nominations are sought for the position of Chair of the Department of Biological Sciences at Simon Fraser University. The Department has 35 faculty members whose teaching and research interests cover all the modern areas of Biological Sciences. There is a graduate enrolment of some 160 students, and external research grant support in 1988/89 was $2.4 million.

A Departmental Chair appointment is for up to five years and is renewable; the salary is negotiable. The appointment would normally carry tenure. Candidates should have an excellent record in research and a demonstrated ability as an academic leader.

Applications or nominations should be forwarded, by January 15, 1990, to the **Dean of Science, Simon Fraser University, Burnaby, B.C. V5A 1S6.**

This advertisement is directed to people who are eligible for employment in Canada at the time of application. S.F.U. offers equal employment opportunities to qualified applicants. (NW4626)A

MOLECULAR IMMUNOLOGIST

The Department of Microbiology, Immunology and Parasitology, New York State College of Veterinary Medicine, Cornell University, seeks candidates for a senior faculty position in Immunology. Rank and salary will be commensurate with experience. The successful candidate will be expected to have an independent, competitively funded research program emphasizing molecular or cellular aspects of immunology. In addition, it is anticipated that she/he will assume a leadership role in immunology in the department, contribute to the teaching of the discipline, and have the opportunity to participate in a campus wide program in Immunology. Applicants should have a PhD, DVM/PhD or MD/PhD and several years' research experience. This position is part of a major commitment by the department to use molecular approaches in biomedical research. Applications including a curriculum vitae, outline of future research plans and the names and addresses of three referees should be sent to **Dr. Roger J. Avery, Chairman, Department of Microbiology, Immunology and Parasitology; College of Veterinary Medicine, 616 Veterinary Research Tower, Cornell University, Ithaca, NY 14853-6401** by February 15, 1990. Telephone inquiries will be welcomed (607/253-3400).

Cornell University is an equal opportunity/affirmative action employer/educator. (NW4738)A

ASSISTANT PROFESSOR

Applications are invited for a position at the level of assistant professor (tenure track) in the Department of Chemistry at Stanford University, with primary research and teaching interests in the general area of inorganic chemistry. Applicants must be strongly motivated toward creative research and have a commitment to teaching at the undergraduate and graduate levels. In applying, please send curriculum vitae, list of publications, a brief statement of research interests (three pages or less) and, in addition, have three letters of recommendation sent to **Professor Harden M. McConnell, Chairman, Department of Chemistry, Stanford University, Stanford, California 94305.**

Stanford is committed to Equal Opportunity through Affirmative Action in employment, and we are especially eager to identify minority persons and women with appropriate qualifications. Applications should be received by January 15, 1990. (NW4629)A

United Medical and Dental Schools of Guy's and St Thomas's Hospitals

RESEARCH ASSISTANT 1B

DIVISION OF PHYSIOLOGY

required in our St Thomas's Campus to use microepifluorescence techniques to study intracellular ions in isolated cells. Other duties involve preparation of cells for epifluorescent studies and day to day running of the laboratory. Candidates should have a good BSc degree. Appointment for a period of one year.

Salary range £9,816-£12,381 plus £1,650 LWA according to age, qualifications and experience. For a job description please contact Mrs F Diamond on 01-928 9292 ext. 3341.

Applications with full CV and names and addresses of two referees to the **Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** by 11 January 1990 quoting reference STH/PHYS/465. (2350)A

THE UNIVERSITY OF WOLLONGONG

P.O. BOX 1144, WOLLONGONG, N.S.W. 2500
PHONE (042) 27 0555 FAX (042) 27 0433 TELEX 29022
AUSTRALIA

The University of Wollongong has established a reputation as an energetic, innovative institution. It has grown rapidly in recent years and currently enrols some 8,000 students in seven faculties, Arts, Commerce, Education, Engineering, Health and Behavioural Sciences, Mathematical Sciences and Science.

Professor of Applied Mathematics

Applications are invited from outstanding scholars whose teaching and research activities will further enhance the reputation in Applied Mathematics of the University. The Department of Mathematics has an established research programme in "Engineering and Industrial Mathematics" which also includes members from the Faculty of Engineering. The appointee will be expected to take a leading role in this research programme through his or her own research, industrial collaboration and enterprise. The research and teaching of the Department covers the whole spectrum of Pure and Applied Mathematics and Statistics and the successful applicant will also be expected to contribute to the balanced development of these disciplines.

A restructuring will, from next year, place the Department in a Faculty of Informatics with the Department of Computing Science, Electrical and Computer Engineering and an Information Technology and Communication Unit. Further information from Professor David Griffiths 61 42 27 0845. Reference AC 89-80. Closing date 19 January, 1990.

Professors may, with approval, undertake a limited amount of consultative work. Appointment as Head of Department on a rotating basis is a requirement. The University reserves the right to fill an advertised Chair by invitation. Remuneration will be based on a salary of $A65,847 per annum and includes a flexible benefits package.

Initial inquiries may be made to Mr Ross Walker 61 42 27 0934. Applications should quote the Reference, contain details of qualifications, employment history, research interests, publications and the names and addresses of three referees and should be addressed to the Recruitment Officer (Academic Staff). A secure fax is available at 61 42 27 0700. Please mark envelope "Confidential-Appointment".

Equality of employment opportunity is University Policy. (W6852)A

POSTDOCTORAL POSITIONS IN IMMUNOLOGY AND MOLECULAR VIROLOGY

Two positions are available immediately to study apitopes of human immunodeficiency virus (HIV-1) recognized by cytotoxic T lymphocytes (CTL). Approaches being taken include the construction of recombinant viral vectors, cloning of human anti-HIV CTL and use of synthetic peptides. Experience in immunology or molecular biology/virology is desirable. Send curriculum vitae and the names of three references to: **Dr. Ken Rosenthal, Department of Pathology, McMaster University Health Sciences Centre, Hamilton, Ontario, Canada L8N 325.** (NW4759)A

POSITION AVAILABLE

RESEARCH ASSOCIATE PROFESSOR OF PHARMACOLOGY — To work on the isolation of insulin mediator and anti-mediator substances and elucidate their structure, mechanism of action and biosynthesis.

Candidates should have a strong chemical background in the isolation and identification of biological components knowledge of physico-chemical techniques such as mass spectrometry, mono spectroscopy would be an advantage. Competence and biological assay is essential. Applicant should be well informed in the mechanism of insulin action. Previous experience with insulin mediator would be an advantage.

Send Curriculum Vitae to **Dr. Joseph Larner, Department of Pharmacology, University of Virginia, Charlottesville, Virginia 22908.** An Equal Opportunity/Affirmative Action Employer. (NW4739)A

DEPARTMENT OF CHEMISTRY

The Department of Chemistry and Biochemistry at Concordia University, Montreal hopes to make a tenure-track appointment in Biochemistry to commence in August 1990. The Department has strong research interests in the interface of Chemistry and Biology in Bioinorganic Bioorganic and Biophysical Chemistry. We are seeking an outstanding candidate with research interests in areas of Basic Biochemistry, such as: Enzymology, Metabolism or Membrane Enzymes, that will compliment our existing interests. The successful applicant will have to have a Ph.D. and Post Doctoral experience, will be required to establish a vigorous Research Program that will attract external funding, and teach Biochemistry effectively at the Undergraduate and Graduate levels. Start-up assistance will be provided by the University, while external funds are available from Quebec and federally from the Natural Sciences and Engineering Research Council of Canada. The current salary floor for Assistant Professors is $33,278 per year.

Concordia University is a predominatly English Institution located in downtown Montreal close to three other Research Intensive Universities. There are 29 full-time Faculty in the Department of Chemistry and Biochemistry with active Research Program in Biochemistry, Organic, Inorganic and Physical Chemistry, Photochemistry, and Material Science. At the present time there are 50 Graduate Students enroled at the M.Sc. and Ph.D. levels in the Department and about 15 of these are doing Research in the area of Biochemistry. The Department is housed adjacent to the Biology Department and this facilitates collaborative Research interactions between Biochemists in the two Departments.

All qualified individuals are encouraged to apply, but in accordance with Canadian Immigration requirements, this Advertisement is primarily directed to Canadian citizens and permanent residents. Applicants should supply a Curriculum Vitae, a short Resume of Research interests, a summary of start-up requirements and arrange for three letters of reference to be sent to:

Dr. P.H. Bird
Department of Chemistry and Biochemistry
Concordia University
1455 de Maisonneuve Blvd., West,
Montreal, Quebec
H3G 1MB (NW4758)A

IMPERIAL COLLEGE OF SCIENCE, TECHNOLOGY AND MEDICINE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT IN NEUROSCIENCE

Applications are invited from persons possessing, or who will shortly possess, a PhD in the neurosciences for an appointment for up to three years, to work on the cell biology of demyelination and remyelination in models of Multiple Sclerosis. The successful candidate will join a group investigating the cell biology of CNS glial cells during normal and abnormal development, and their response to damage. Previous experience in tissue culture, immunohistochemistry and neuroimmunolgy would be particularly useful.

The post is tenable from 1st March 1990. Initial salary will be in the range £14,031 – £15,177, inclusive of London weighting, on the RA1A scale. Applications should be made in writing (full CV, publication list, summary of research to date, and names and addresses of two referees) to **Dr Richard Reynolds, Department of Biochemistry, Imperial College, Kensington, London SW7 2AZ.** Interested persons can call Dr. Reynolds on 01-589 5111 ex 4135. (2347)A

POSTDOCTORAL POSITION

Available immediately for a Ph.D. in immunology to study T cell recognition. The work will focus on the role of CD8 and CD4 molecules and will include both molecular and cellular investigations. Previous experience with cellular immunological and/or molecular biological techniques would be an advantage but is not essential.

Send CV, including names and tel. no.'s of 2 references to **Dr. Terry Potter, Division of Basic Immunology, Dept. of Medicine, National Jewish Center, 1400 Jackson St., Denver, CO 80206.** (NW4761)A

PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

DIVISION OF PATHOLOGY

Senior Grade Microbiologist (Immunologist) 2 years, MRC.

To work on development and application of a primate model of human AIDS. This project is an essential part of the MRC AIDS-drected programme, as a model is needed for testing vaccine approaches and potential therapies and for studies of pathogenesis. The project is progressing well and offers unique opportunities for analysis of cell-mediated immune responses to infection. Advances in this area will be crucial to rational vaccine formulation.

The candidate for this post will ideally be post-doctoral, possessing a good understanding of cellular immunology and with research experience in this area, preferably in relation to virus infection. Experience in haematology or flow cytometry would also be valuable. However, applicants with research experience in areas such as virology or cell biology would be considered for the post.

The successful applicant will have the opportunity for contact with scientists working in AIDS research both at CAMR, where there is a large team engaged on a variety of projects, and within the MRC AIDS Directed Programme.

Salary will be on the scale of £11,778-£15,394 (under review).

National Health Service terms and conditions will apply.

This post may be discussed informally with Dr M Cranage or Dr T Ashworth on Ext 2317/2342.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wilts SP4 0JG, Telephone Idmiston (0980) 610391 ext 240, to whom completed forms should be returned by 5th January 1990 quoting post number 1130. (2344)A

Washington University, St. Louis

Postdoctoral – Research Associate Level

Applications are invited for two postdoctoral positions to investigate the cellular and molecular biology of bone development. A background in protein chemistry and/or molecular biology is desirable. Ongoing studies utilize cell culture and monoclonal antibodies to investigate cell surface molecules and factors influential in their expression. Positions offer competitive salaries and are available immediately. Curriculum Vitae and the names and addresses of two references should be sent to **Dr. Philip Osdoby, Department of Biomedical Sciences, Washington University, 4559 Scott Avenue, St. Louis, Mo. 63110.** (NW4748)A

Postdoctoral Position

Mammalian Oocyte Development

A postdoctoral position is available in the laboratory of Dr. John Eppig to study mammalian oocyte development. Emphasis will be in two areas (1) the initiation of oocyte maturation, and (2) the expression and role of the *Mos* proto-oncogene in oocyte development. Experience in techniques of molecular biology is desirable.

Candidates should be available between the Spring and Fall of 1990. Send a CV and a letter of application describing qualifications to **Dr. John Eppig, The Jackson Laboratory, Bar Harbor, ME 04609 USA.** Three confidential letters of reference should also be provided.

(NW4753)A

Chair, Department of Biochemistry

TEMPLE UNIVERSITY SCHOOL OF MEDICINE

The search for the Chair of the Department of Biochemistry has been extended. Candidates should have proven leadership ability and must be nationally recognized for their scientific contributions to biochemistry or related fields. The successful candidate must have demonstrated interest and ability in effective teaching and the capability of providing the administrative leadership to continue and extend the department's established strengths in research, teaching and service. An excellent opportunity exists to expand an already strong department and its collaborations with other Basic Science departments, as well as with the Fels Research Institute for Molecular Biology and Cancer Research, and the Thrombosis Center. Applications will be accepted until 15 February 1990 and should include curriculum vitae, a summary of current research, a description of teaching and administrative experience, and the names, addresses and telephone numbers of three or more references. Mail applications to: **Helen R. Buckley, Ph.D, Chair of the Search Committee, Department of Microbiology and Immunology, Temple University School of Medicine, 3400 North Broad Street, Philadelphia, PA 19140.**

Affirmative Action/Equal Opportunity Employer.

Choose (NW4756)A

TEMPLE UNIVERSITY

CT BIOMED BAD DEYNHAUSEN

KNOWLEDGE ENGINEER

The "Center of Technology Transfer Biomedicine" is a new Institute founded in collaboration with the University Bielefeld, located at a Medical Center in Ostwestphalia and a spa with campus like surrounding.

The "Division Expert Systems Biomedicine", invites a qualified person (Ph.D. or relevant experience in the field of biomedical sciences) to participate in the area of knowledge based systems. Salary depending on qualification: Pound 15.000-20.000. Native English speaker and knowledge in German required.

Further details: **Dr. B. Petkoff, Chief, Expert Systems Biomedicine, ZTB GmbH Bad Oeynhausen, W. Germany 4970,** Phone: 49-5731 9929. Equal Opportunities Employer.

(W6867)A

UNIVERSITY OF REGENSBURG, FRG

5 YEARS PROFESSORSHIP (C3) IN CELLULAR NEUROBIOLOGY

Applicants should be qualified in neurobiological research at the cellular level and adequately familiar with modern methods. Cooperation within resident Special Research Programme on Sensory Systems is requested.

Candidates must be qualified for temporary professorship by Habilitation or equivalent qualifications as senior scientist.

C.V., list of publications, and summary of research achievements should be sent to the **Dean, Faculty of Biology and Preclinical Medicine, University, Universitätsstr. 31, D-8400 Regensburg, FRG until January 30, 1990.** (W6848)A

THE UNIVERSITY OF MELBOURNE

RESEARCH FELLOW GRADE 1 (EXTENDIBLE TENURE)

CELL BIOLOGY FERTILIZATION IN PLANTS

School of Botany

A postdoctoral research position is available for studies of cell-cell interactions during fertilization in seed plants as part of a three year project funded by the Australian Research Council led by Dr. J. M. Pettitt, Department of Pathology and Immunology, Monash Medical School, and Professor Bruce Knox, School of Botany, University of Melbourne. Candidates should have a Ph.D. with experience in monoclonal antibody technology, protein chemistry or molecular biology.

The position is available for three years subject to the continued funding by A.R.C.

Further information concerning the position or the department may be obtained from Professor R. B. Knox, telephone (613) 344 5063 or FAX No. (613) 344 7049.

Salary is in the range: $A27,953-$A31,808 per annum (Research Fellow Grade 1).

Closing Date: 3 January 1990.

Position Number: 606A075

Written applications should reach The Director, Personnel Services as stated below.

Applications, in duplicate, including names, addresses and fax numbers of at least three referees and quoting the relevant position number should be addressed to The Director, Personnel Services, The University of Melbourne, Parkville, Victoria, 3052, Australia.

An equal opportunity employer. (W6849)A

HENDRIX COLLEGE
Biology Department
Two faculty positions:

(1) Developmental Biologist

to teach zoology, anatomy and embryological development;

(2) Microbiologist

to teach general microbiology and advanced course(s) in candidate's speciality. Both positions are tenure-track assistant professor, entry-level, and require participation in teaching introductory biology, direction of undergraduate research (start-up funding is available), student advising, and faculty governance.

Apply by February 1, 1990 to: **Dr. Bruce Haggard, Chairman, Biology Department, Hendrix College, Conway, AR 72032.**

An Equal Opportunity/Affirmative Action Employer (NW4736)A

SUNDERLAND HEALTH AUTHORITY

Leukaemia Lymphoma Resear
Laboratory

POST DOCTORAL RESEARCH ASSISTANT

Required from January/Februa 1990 to fill vacancy arising fro present incumbent gaining post U.S.A. Appointment initially f 1 year, renewable subject to pe formance. This is a spacious, we equipped laboratory, generous funded.

Experience in culture, stim lation and functional analys of human blood mononucle cells essential and familiarity wit ELISA techniques expecte Current research includes stud of immune consequences c blood transfusion, immuno pathology of Hodgkin's and othe lymphomas.

Salary on scale £10,458 £16,665, according to experienc and qualifications. Drive, initia tive and enthusiasm are essentia and will be rewarded. For furthe details/visit to department, tel 091 5656256 ext. 248. (Dr Kay).

We aim to be an Equal Oppor tunities Employer. (2298)A

RESEARCH ASSOCIATES IN REPRODUCTIVE BIOLOGY

UNIVERSITY OF MISSOURI

Two postdoctoral positions for recent Ph.D.s with experience in biochemistry, molecular endocrinology, or reproductive physiology to study either the biosynthesis, expression and function of alpha-interferons and 73 related lymphokines produced by mammalian embryos or the progestational control of protein synthesis and secretion in the mammalian uterus. Submit curriculum vitae and names of three references to **Dr. R.M. Roberts, 158 ASRC, University of Missouri, Columbia, MO 65211.**

(NW4752)A

MOLECULAR AGING

Two postdoctoral positions now available for persons trained in molecular techniques relevant to characterizing novel senescent-related genes and their cognate proteins. Support available for two or more years. Salary commensurate with experience. Send CV and names of four referees to **Dr. S. Goldstein, University of Arkansas Medical School and Veterans Hospital, 151 Research, 4300 West 7th Street, Little Rock, Arkansas, 72205,** tel. (501) 660-2069; Fax (501) 661-1202, ext. 3980.

(NW4747)A

BIOLOGICAL NMR SPECTROSCOPISTS

The Pittsburgh NMR Center for Biomedical Research is searching for one or possibly two Ph.D.-level scientists with experience in applications of NMR spectroscopy and imaging to metabolic studies in animals. These are full-time staff appointments and salary depends on experience and qualifications. Responsibilities include collaborative interaction with medical scientists, probe construction, and development and implementation of new NMR techniques. The Center is multidisciplinary involving scientists from both the University of Pittsburgh and Carnegie Mellon University. The Center houses a 4.7-Tesla, 40-cm Bruker BIOSPEC II and a 2.4-Tesla rapid imaging spectrometer is under construction. In addition, center personnel have access to a 7.0-Tesla, 15-cm bore Bruker BIOSPEC II and Bruker AM-300 and AM-500 spectrometers.

Applicants should send a Curriculum Vitae and have three letters of recommendation sent to: **Dr. Chien Ho. Pittsburgh NMR Center for Biomedical Research, Carnegie Mellon University, 4400 Fifth Avenue, Pittsburgh, PA 15213.** Review of applications will begin on February 15, 1990 and will continue until suitable candidates are recruited. Carnegie Mellon University is an Affirmative Action/Equal Opportunity Employer. (NW4745)A

Project Investigator

who will conduct independent research in the isolation of total RNA and poly(A+)–RNA. Construction, screening and expression of cDNA libraries. Molecular cloning. DNA sequencing. Northern and Southern blotting. Recombinant DNA methods. Purification and characterization of proteins. Tissue culture of mammalian cells. Ph.D. Degree in Biochemistry/Molecular Biology or Related Field. One year Research Training. One year Molecular Biology Research Experience. A minimum of 3 publications in the area of Molecular Biology and in particular in construction, screening, and expression of cDNA libraries and protein purification. 40 hours/week. $21,800 annual salary. Contact **Texas Employment Commission, Houston, Texas** or send resume to **Texas Employment Committion, TEC Building, Austin, Texas 78778.** Job Order #5757185. Ad Paid for by an Equal Opportunity Employer. (NW4763)A

UNIVERSITY OF TASMANIA

Applications are invited for suitably qualified men and women for the following position.

RESEARCH FELLOW IN PHYSICS

(Ref. 165/89)

The Department of Physics requires a theoretical physicist/mathematical physicist to work on a joint University of Tasmania/University of Queensland Australian Research Council funded research project on infinite dimensional algebras and field theory applications. Candidates should have a Ph.D. and relevant research experience.

The position is available for up to three years, and the appointment will be in the Junior Research Fellow scale (A$27,953 to A$31,808 per annum), with the possibility of assistance with removal expenses.

For further information contact Dr P.D. Jarvis, tel. (61.02) 202401, or Dr M.D. Gould, tel. (61.07) 3772673.

Applications quoting the reference number and including curriculum vitae and the names and addresses of three referees should be addressed to reach the Staff Officer, University of Tasmania, G.P.O. Box 252C, Hobart, Tasmania 7001 by 9 January 1990.

The University is an Equal Opportunity Employer. (W6842)A

Molecular biologist

Position open for a molecular biologist. Research project includes demonstration of the gene, and receptor expression and the role of cytokines in human endometrium. Send CV to **Dr. Tabibzadeh, Dept of Pathology, Elmhurst Hospital, 79-01 Broadway, Elmhurst, NY 11373 or call: 718-830-1685.** (NW4755)A

POSTDOCTORAL POSITION

Available for investigating regulation of cell-to-cell communication via gap junctions. Experience with protein chemistry and molecular biology or patch clamp methods preferred. The position is available for up to 3 years with possible extension.

Send CV and 3 letters of reference to **Dr. Camillo Peracchia, Department of Physiology, Box 642, University of Rochester, Medical Center, Rochester, New York 14642, USA.** (NW4728)A

BIOSCIENCE WRITER

with business reporting experience, some computer (Macintosh) friendliness, for position as Associate Editor on periodical of major N.Y. publisher. Salary, plus perks, commensurate with qualifications. [An equal op. employer]. Resume to **Box No. NW4760, c/o Nature, 65 Bleeker St., New York, NY 10012.** (NW4760)A

STANFORD UNIVERSITY PSYCHOLOGY DEPARTMENT

is seeking applicants for a professorship at any level in Physiological Psychology starting Autumn 1990. Scholars with a strong research record in sensory processes or the biological basis of cognition or behavior are encouraged to apply. Send curriculum vitae, copies of scholarly papers, and three letters of recommendation to: **Physiological Search Committee, c/o Mrs. Frances Martin, Dept. of Psychology, Stanford Univ., Stanford, CA 94305-2130** by February 15, 1990. *Stanford University is an Equal Opportunity Employer.* (NW4764)A

STUDENTSHIPS

UNIVERSITY OF CAMBRIDGE

Research Opportunities in Physical Chemistry and Chemical Physics

Applications are invited from students expecting good Honours degrees in Chemistry, Physics or Materials Science for studentships which will become available from October 1990 in the following areas:

☆ ATMOSPHERIC CHEMISTRY
☆ GAS PHASE KINETICS AND PHOTOCHEMISTRY
☆ HETEROGENEOUS CATALYSIS
☆ SOLID STATE CHEMISTRY
☆ SPECTROSCOPY
☆SURFACE SCIENCE
☆ X-RAY DIFFRACTION AND ELECTRON MICROSCOPY

CASE and Quota SERC Studentships as well as fully funded industrially supported Studentships are available. Further details and information concerning visits to the Department may be obtained (quoting reference RS/NT) from **Professor D. A. King, Department of Chemistry, Lensfield Road, Cambridge CB2 1EW.** (2352)F

UNIVERSITY OF OXFORD

RESEARCH STUDENTSHIPS

The Department of Human Anatomy invites applications for several research studentships in 1990, including the possibility of a Wellcome Trust Prize studentship. The department is well endowed with modern research facilities and at present research interests cover the following topics: neuroscience, endocrinology, membrane physiology, developmental and cell biology. Detailed information on these research programmes can be obtained from the Department.

Applicants, who should have or expect to be awarded a first class or upper second honours degree in one of the biological sciences, should send a copy of their curriculum vitae, a statement of their research interests, and the names of two referees to: **Professor R W Guillery, FRS, Department of Human Anatomy, South Parks Road, Oxford, OX1 3QX, by 15 January 1990.** (2341)F

AWARDS

NASA PLANETARY BIOLOGY INTERNSHIPS

The Marine Biological Laboratory, Woods Hole, MA, invites applications from graduate students and seniors accepted to graduate programs for awards of $2000 plus travel to participate in research at NASA centers and collaborating institutions for appoximately 8 weeks. Typical intern programs include: global ecology, remote sensing, microbial ecology, biomineralization, origin and early evolution of life. Application deadline: 1 March 1990.

For information/applications, contact: Greg Hinkle, Planetary Biology Intern Program, Department of Botany, University of Massachusetts, Amherst, MA 01003.

An Equal Opportunity/Affirmative Action Institution. (NW4737)N

THE HEART RESEARCH INSTITUTE, SYDNEY, AUSTRALIA

RESEARCH FELLOWSHIPS AND ASSISTANTSHIPS AVAILABLE IMMEDIATELY

The Heart Research Institute is a new dynamic National Institute, comprising five major groups with interests in cell biology, immunology, molecular biolcgy, biochemistry and coagulation with particular emphasis on mechanisms of atherogenesis. Several research fellowships and assistantships are available at the Heart Research Institute as a result of recent successes in funding applications to the Australian Research Council, the National Heart Foundation, the National Health and Medical Research Council, the New South Wales Cancer Council and other bodies. Applications are invited in the following areas:

1. Effects of thermal stress on the release of coagulation-associated molecules by human endothelial cells: Dr. Joan Dawes. Relevant Reference: Human Pathology, Vol. 18, 234 (1987).
2. Free radical damage to proteins and the roles of protein hydroperoxides as reactive intermediates (3 positions: Prof. Roger Dean). Relevant References: Biochem J. 250, 87 (1988); 256, 205 (1988); Analytical Biochemistry 176, 353 (1989).
3. Glycosaminoglycan degradation by macrophages and the possible role of glycosaminoglycan fragments in atherogenesis: Prof. Roger Dean. Relevant Reference: Bioscience reports, 4, 1017 (1984).
4. One Molecular Biologist and one Cell Biologist to study a newly described chemotactic factor in inflammation: Dr. Carolyn Geczy. Relevant Reference: J. Immunol. 141, 2110 (1988).
5. Oxidation of low density lipoprotein and its influence on atherogenesis. Dr. Wendy Jessup. Relevant Reference: Biochemical Journal 262, 707, (1989).
6. Roles of metallothionein in protection against free radical-mediated cardiotoxicity by adriamycin: Dr. Jeremy Simpson. Relevant References: Toxicology 53, 231, (1988); Biochemical J. 250, 87 (1988).
7. Molecular mechanisms of endocytosis with special reference to the LDL receptor related protein: Dr. Keith Stanley. Relevant Reference: Nature 341, 106, (1989).
8. Mode of action and interaction of antioxidants: Dr. Roland Stocker. Relevant reference: Science 235, 1043 (1987).

Most positions are available for two or three years with the possibility of continuation. The position associated with Project 6 is a part-time position for one year in the first instance. Salaries are in accordance with NH&MRC scales. Further information is available on request to the named members of the staff of the Heart Research Institute. Written applications should be made to:

Professor Roger Dean, Director, Heart Research Institute,
145 Missenden Road, Camperdown, Syndey, NSW 2050
AUSTRALIA
including c.v., publications list and the names of two referees.
Phone: **+61 (2) 550 3560, Fax: +61 (2) 550 3302.**

(W6844)E

FELLOWSHIP IN NEUROIMMUNOLOGY

Position is available for post-doctoral Fellowship in Neuroimmunology. Candidate should have Ph.D., or M.D./Ph.D. degree. Research experience in Immunology for a minimum of 2 years is essential. Candidates with experience in molecular biology will be preferred.

Please send curriculum vitae and three letters of recommendation to: **Sudhir Gupta, M.D., University of California, Irvine, C264A Med Sci I, Irvine, CA 92717.** Telephone: (714) 856–5818.

UCT is an Equal Opportunity and Affirmative Action Employer.

(NW4741)E

UNIVERSITY OF GLASGOW
POSTDOCTORAL FELLOWSHIP
in Molecular Neurobiology

A 3-year appointment supported by the Medical Research Council is available for work on cloning and functional analysis of genes characteristic of a particular class of mouse CNS neurone, in the laboratory of Professor R. Wayne Davies. Candidates should have good practical experience in recombinant DNA technology, and will have the opportunity to learn transgenic and chimaeric mouse technology. The laboratory is in the new Robertson Institute for Biotechnology within the Department of Genetics which is active in many fields ofmolecular biology research.

Salary will be within Research Assistant 1A scale £10,458-£12,879 per annum.

Further particulars may be obtained from **Professor R. Wayne Davies, Robertson Institute for Biotechnology, University of Glasgow, Glasgow. G12 8QQ** (041 339 8855 ext. 5102), to whom a letter of application with full c.v. together with the names and addresses of three referees should be sent on or before 9th February, 1990. (2339)E

COURSES & CONFERENCES

ÉCOLE EUROPÉENE DE BIOLOGIE THÉORIQUE: EBT90

Abbaye de Solignac, France. 2–22 Septembre 1990

Title: Structures and functions in biological organizations (theoretical basis for modeling and simulation).

Aims: Complexity in biological organizations necessitates the development of particular methods (modeling and simulation); experimental biology suffers from a lack of communication between life sciences and physics and mathematics. So, although experimental methods within these sciences may be different (there is no homeostasis in physics systems but homeostasis is the basis of the definition of experimental procedure validity in life sciences), the structure of the processes (unstable state typology, spatial heterogeneity distribution, dynamics structures — oscillations, chaos, limit cycle . . .) are likely to be described by the same types of formalisms. Theoretical biology utilizes this property to build new methods to answer the question of complexity in biological organizations.

Maximum number of participants: 50.

Languages: Courses and lectures in French or English depending on speaker; supporting documents (courses and lectures texts) will be available.

Programme: First week: optional courses (33 hours); second and third weeks: lectures (63 hours)

— *optional course "biology":* General biology, Symetry and polarity, Main functions and controls (animal physiology), Morphogenesis and full plant physiology, Genetics and evolution, Evolution and diversity, From ecosystem to biosphere.

— *optional course "Mathematics":* Basic linear algebra, Differential equations, Stochastic modelling and statistical approach, Fundamental physics: the main formalisms, Introduction to PDE-modeling, Recurrent equations, Qualitative dynamics.

— *Lectures:* Epistemology, Singularities and catastrophs, Dynamical systems, System sciences and cybernetics, Physics, Form analysis, Automata, Theoretical computering, Neurology, Electrophysiology, Genetics, Metabolic networks, Morphogenesis, Ecological dynamics.

Cost: 1180 EEC ecus (*including accommodation and documents*).

EBT90 is organized by the Société Française de Biologie Théorique *with the support of the INRA Formation Permanente office.*

EBT90 is granted by the Commission des Communautés Européennes and by the Conseil Régional du Limousin.

Informations and detailed programme:

Dr. A. Kretzschmar, INRA, B.P. 91, 84140 MONTFAVET - France.

Registration form (to be requested before 28 February 1990):

Formation Permanente INRA (Att. Pascaline Garnot), 145 rue de l'Université, 75341 PARIS Cédex 07 - France.

INDUSTRY, UNIVERSITIES AND WEALTH CREATION

Worldwide Trends and Opportunities for Europe

Queens' College, Cambridge
4-6 July 1990

This international conference will bring together industrialists and academics from Europe, USA and Japan, to explore collaboration between companies and universities, especially in research and new business generation.

Authoritative perspectives will be presented by speakers prominent in their fields, for example, Sir Geoffrey Allen (Unilever), Professor P Fasella (EC, DG XII), Professor H Fusfeld (USA).

The intention is to highlight opportunities for Europe and to stimulate specific action to be taken up by European companies and universities.

Designed to interest senior industrialists, academics and government officials who are decision-makers and leading players in the European scene, the main headings for the 4 sessions of this 2½-days conference programme will be:–

1. International Perspectives: strategic approaches in Europe, the USA and Japan
2. Case material illustrating worldwide experiments in industry/university partnerships in research
3. Industry/Higher Education interaction in the development of new business.
4. Opportunities and the way ahead for Europe.

Those who have had experience of practices in this field in America and Japan will also be welcome.

For further details, please contact:–

continued on page 16

SITUATIONS WANTED

BIOCHEMICAL PHARMACOLOGIST in permanent position seeks a new job in 1990. Aged 42, unusually wide scientific experience, Oxford degree and doctorate. Special interests include drug metabolism, cardiovascular pharmacology and the endothelial derived factors (publications). Fluent German. Apply Box No. W6861, c/o Nature, 4 Little Essex St., London WC2R 3LF.

(W6861)B

MISCELLANEOUS

KNOWLEDGE is one bit (of variable strength) per synapse. Fo reinforcement to work it must be delivered to the correct synapse (or failing that the correc neurone). This can be bes achieved if there is a binary enumeration of synapses (or failing that of neurones). The homeobox deletions, the cell lineages of caenorhabditis and the symmetry of vitiligo can all be interpreted as evidence of the enumeration of biological structures. — Box No. 2338, c/o Nature, 4 Little Essex St., London WC2R 3LF.

Call for Papers

Announcing an important new quarterly journal for 1990 on the innovative field of GENE TRANSFER . . .

Human Gene Therapy

Editor-in-Chief: W. French Anderson, M.D.

Human Gene Therapy, a new quarterly journal, answers the need for a central forum dealing with all aspects of gene transfer in mammals.

As a major new frontier, gene therapy deserves the focused attention of its own publication. Since human gene transfer has been approved for clinical trials, we are at the threshold of an era where this new therapeutic approach will probably be used in the treatment of presently incurable diseases. Several therapy protocols are being tested in preclinical animal trials. Cancer, AIDS, and genetic diseases are the initial targets.

Original scientific contributions will include:

- ***Techniques for gene transfer into mammalian cells***
- ***Construction and testing of retroviral vectors***
- ***Examination of the life cycle of retroviruses where it is applicable to the use of retroviral vectors***
- ***Regulatory mechanisms for controlling gene expression***
- ***Animal models for human diseases***
- ***Studies evaluating gene transfer and expression in animals***
- ***Results of preclinical safety and efficacy studies***
- ***Results of clinical studies***

Other topics in *Human Gene Therapy* will include ethical, legal, regulatory, social, and commercial considerations.

Human Gene Therapy will address itself to all aspects of this specific field including broader social issues; additionally, this important new publication will serve as a resource for current information as well as a repository for future reference.

Biochemical Endocrinology Symposium

The Twelfth Annual University of California, Riverside-Nichols Institute Symposium on Cellular and Molecular Endocrinology will be held Thursday and Friday, March 29 and March 30, 1990 on the University of California, Riverside campus at the foot of the Box Springs Mountains.

The purpose of the meeting is to foster communication among scientists who are interested in the cellular, biochemical and structural aspects of endocrinology. The meeting will have four sessions devoted to the topics of (a) Control of Cell Growth, (b) G-Protein and Regulation of Ion Channels, (c) Regulation of Gene Expression and (d) Animal Disease Models.

Thirteen internationally recognized scientists will present lectures on their work in these areas. They include the following: Donald M. Bers (Riverside), Ralph A. Bradshaw (Irvine), Arthur M. Brown (Houston), Richard Cate (Cambridge), Susanna Cotecchia (Durham), Sidney Fleischer (Nashville), Richard D. Klausner (Bethesda), Jeffrey A. Ledbetter (Seattle), Donald P. McDonnell (Houston), John W. Newport (San Diego), Paul M. Quinton (Riverside), Timothy A. Stewart (South San Francisco), and David O. Toft (Rochester).

Registration fees for the meeting are $25.00 per participant ($15.00 for postdoctoral students/fellows; $10.00 for students and $125.00 for physicians wishing to enroll in the Continuing Medical Education [CME] Program [Category 1] through the University of California, Los Angeles School of Medicine).

For registration and further information please write: **Dr. Anthony W. Norman, Endocrinology Symposium, Division of Biomedical Sciences, University of California, Riverside, CA 92521; telephone: (714) 787-5705; FAX: (714) 787-5504.**

FOR COVERAGE OF TODAY'S BIOTECHNOLOGY

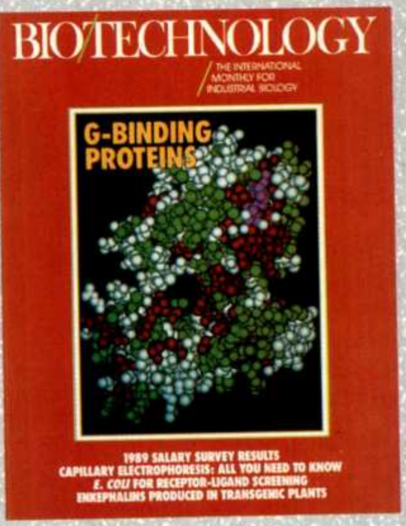
INDUSTRY TURN TO THE SPECIALIST

BIO/TECHNOLOGY

Each month, BIO/TECHNOLOGY offers its readers more news, features, evaluations and up-to-the minute information than any other biotechnology publication.

TRULY INTERNATIONAL PERSPECTIVE

Bio/Technology's scientific correspondents report from around the world on vital details of commercial and scientific strategies, government regulations, funding issues, new laboratories, scale up, financial news, patents and new biological materials. This essential information helps you monitor competition and developments worldwide, allowing you to make informed decisions within your work.



BIO/TECHNOLOGY
THE INTERNATIONAL MONTHLY FOR INDUSTRIAL BIOLOGY
G-BINDING PROTEINS
1989 SALARY SURVEY RESULTS
CAPILLARY ELECTROPHORESIS: ALL YOU NEED TO KNOW
E. COLI FOR RECEPTOR-LIGAND SCREENING
ENKEPHALINS PRODUCED IN TRANSGENIC PLANTS

COVERAGE OF ALL BIOTECHNOLOGY RELATED DISCIPLINES

From soil improving bacteria to animal husbandry and from transgenic mouse milk to fermentation, Bio/Technology covers all biotechnology related disciplines. The magazine's in-depth editorial deals with basic research techniques right up to large scale production.

THE VERY BEST ORIGINAL BIOTECHNOLOGY RESEARCH

Bio/Technology is the only international journal to publish original research specifically about biotechnology. Each paper is carefully refereed, ensuring that the research you see is of far-reaching importance.

ORDER YOUR SUBSCRIPTION TODAY

For the annual subscription rate of just £70.00 we will send you 12 monthly issues packed with information. Simply complete the order form below.

ORDER FORM
